Departure Delays Are you flying to:			Arrival Delays
Airport	**Delay**		Arrival traffic is experiencing airborne delays of 15 minutes or less.
Logan International Airport, Boston, MA (BOS)	1 hour 46 minutes	Snow	
Newark International Airport, Newark, NJ (EWR)	2 hours 17 minutes	Thunderstorms	
John F. Kennedy International Airport, New York, NY (JFK)	4 hours 3 minutes	Congestion	
LaGuardia Airport, New York, NY (LGA)	3 hours 10 minutes	Emergency	
Chicago Midway Airport, Chicago, IL (MDW)	1 hour 9 minutes	Equipment Outage	
Chicago O'Hare International Airport, Chicago, IL (ORD)	1 hour 10 minutes	Construction	
All other airports	Delays of 15 minutes or less		

When the participants had to find the definition of three aviation-related terms, 16% were unable to find the definition for at least one of them. Therefore, we recommend eliminating the use of these terms when they are not essential. This would eliminate unnecessary detail, simplify the site, and make it easier to use and understand.

Issue 4: User Confusion with Using the View by Region Maps

The fly.faa.gov Web site provides users with a **View by Region** search function that allows users to look up airports by searching in different geographic regions. These regions include the Northeast, North Central, Northwest, Southeast, South Central, and Southwest regions, along with Alaska and Hawaii. When a user uses the **View by Region** function, they are taken to a map that contains only states that are part of a region. However, it is not easy for someone with little knowledge of geography to determine the region for a particular state. The participants got lost when looking for airports that were not on the main U.S. map because they were unable to determine the relationship of regional maps to the main U.S. map. This was especially difficult for states such as Ohio that lie at the edge of a region. These issues make the **View by Region** method difficult for the general public to use and the participants found the **View by Region** maps to be confusing. This issue received a mean severity rating of 4.0, *SD* = 0.0.

One question asked the participants to find delay information for an airport that was not available on the main map or on the **View by Major Airport** menu. Only 71.9% of the participants found the correct answer for this question, indicating that the participants had some difficulty finding information when they needed to drill down on the maps.

There are several recommendations that could alleviate some of the issues related to the use of the **View by Region** method. First, the site could place an outline around the different regions or use color coding to highlight the different regions on the U.S. map. This would help users identify which states belong in which region. The site could display split portions of the main U.S. map on the same page to better orient users to the different regions. To familiarize people with relevant geographic information, the site could label states, both on the main U.S. map and on the smaller regional maps. The site could also offer users a drop-down menu that listed the various airports by state.

Issue 5: Lack of User Knowledge Regarding Three-Letter Airport Identifiers

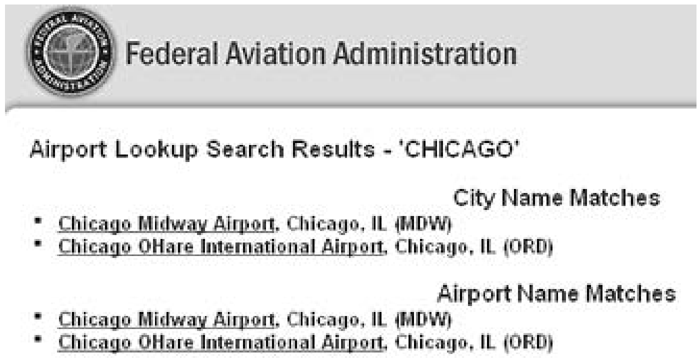
All commercial airports have three-letter identifiers, and using them is an efficient way to obtain delay information about an airport. The site provides a function that allows users to type a three-letter identifier directly into the **Search by Airport** text box, which will take the user to the details page for that airport. It also provides cues to site users by labeling airports on the main U.S. map with their three-letter identifiers (see Figure 1). However, many participants did not know the correct three-letter identifiers for airports and did not use the cues on the main map to determine the correct identifier. This issue received a mean severity rating of 3.3, *SD* = 0.6.

The site should emphasize that the **Search by Airport** text box accepts regular airport names and city names in addition to three-letter identifiers. Although the **Search by Airport** text box does have a label indicating that users can enter city, airport code, or airport name information in this field, we recommend that the Web site provide the user with specific examples to highlight and better explain the different search options.

Issue 6: The Search by Airport Function Returns Redundant and Irrelevant Results

City name searches using the **Search by Airport** function generate an intermediate results page that lists multiple airports. These listings often contain redundant and irrelevant results. This issue received a mean severity rating of 3.3, *SD* = 0.6. For example, a search for Chicago generates a search results page listing two airports: Midway and O'Hare International. The site lists each result twice, once under **City Name Matches** and once under **Airport Name Matches** (see Figure 4). This format is confusing and users may not

Figure 4. The www.fly.faa.gov results page for a Search by Airport search for Chicago



realize that both links take them to the same information. Some participants questioned why the site listed an airport twice. We recommend that the **Airport Lookup Search Results** page consolidate search results and list airports only once in any search results list.

Issue 7: User Spelling and Misspellings and Their Impact on the Search by Airport Function

User spellings and misspellings can have a serious impact on the **Search by Airport** function. In some instances, the correct spelling does not work, but a misspelling does. For example, typing *O'Hare* does not return any results, but *Ohare* does. Typing *LaGuardia* returns no results, but *La Guardia* does. In addition, common misspellings do not produce any results at all, even when the system could provide reasonable guesses about what the user intended. For example, *Newyork* does not produce any search results at all. This issue received a mean severity rating of 3.3, *SD* = 0.6. The participants quickly became frustrated and confused when the site did not return any search results for correct spellings or reasonable misspellings. The search function should always result in a hit when the correct spelling is used, should provide "best guess" search result even when users make spelling mistakes, and should ignore spacing errors.

Issue 8: Inconsistent Use of Pop-up Windows

The fly.faa.gov Web site is inconsistent in its use of pop-up windows. When users access information using the **Search by Airport** method or when they click on the color-coded dots on the main site map, the Web site displays the search results in a pop-up window. However, when users access information using the **View by Major Airport** method, the site displays the same information in the current browser window rather than in a pop-up window. This issue received a mean severity rating of 3.0, *SD* = 0.0.

During the assessment, some participants accidentally closed the browser by clicking the **Close** button when search results appeared in the main browser window. These participants had become accustomed to results appearing in a pop-up window. When search results appeared in the main browser window, they still reacted as if they were in a pop-up window and accidentally closed down the site, along with the browser.

We recommend that the site be more consistent in how it returns search results and **Airport Status Information** pages. Users become confused when the site responds differently to similar actions. If the standard convention of the site is to bring up search results in pop-up windows, then the site should bring up all search results in pop-up windows.

DISCUSSION

The level of aviation-related expertise had an impact on many aspects of user performance. Experts were more likely than novices and moderate-level users to have had some prior interaction with the fly.faa.gov Web site. They were also better at finding delay information on the Web site. Experts appeared to have a better conceptual understanding of the different types of airport delays than both novices and moderate users. Finally, experts indicated that they found the information on the Web site to be slightly more comprehensible than both novices and moderate level users. Although we realize that there may be some performance decrement for people who have no affiliation with the FAA, we expect that their performance and their issues should be most similar to our novice users.

On the basis of performance differences, we recommend that the primary goal of site designers should be to make the site more usable for people who do not have an aviation background. If people in the general public visit this site without an aviation-related background, we would expect them to have substantial difficulty (a) understanding which delays were relevant for them, (b) understanding how airport delays differ from airline delays, and (c) interpreting much of the jargon used by aviation experts. Although both experts and novices use the site, simplifying the Web site should help all users, not just novices. Links to additional information can be provided for expert users.

Subjective reports indicated that the participants were generally satisfied with the fly.faa.gov Web site, and objective data revealed that they could successfully complete most tasks using the site. By evaluating user performance data in conjunction with user comments and researcher observations, we were able to identify a number of human factors issues with the Web site that we would not have identified by relying solely on subjective data.

After identifying issues, we rated each one in terms of its impact on site usability, discussed each issue in detail, identified supporting data when appropriate, and provided recommendations for improving the usability of the Web site. Many of the suggested improvements should be easy to implement and should further increase user satisfaction and site usability.

CONCLUSION

One of the primary lessons that we learned from this usability evaluation is that developers should not simply rely on subjective reports of usability when evaluating e-government Web sites. It is just as important to observe users interacting with a Web site and collect objective performance data to better identify usability issues. By having people use the Web site to find different types of information, we were better able to identify those areas of the site that caused problems for users. To encourage organizations to perform usability evaluations on e-government sites, we should ensure that they provide value by identifying important usability issues that can be remedied through redesign. As we saw in this evaluation, subjective reports often fail to identify these issues. If research on Web site usability fails to identify significant usability issues, it is likely that such evaluations will not be used.

We also found that having researchers rate the severity of usability issues improved our evaluation. Future e-government usability assessments could reap benefits by using this technique. Many times, when a usability assessment is performed, the output of the assessment is a laundry list of issues that usability experts present to site designers. If guidance is given on issue severity or criticality, it is usually ad hoc and is not derived using any formal methodology. By requiring evaluators to explicitly rate each item on frequency, impact, and severity, they are required to think about how and in what ways the problem will affect the user. This user-centric focus is the key element of this methodology. It allows site evaluators to provide designers with a roadmap of how they can best focus their effort to provide a more optimal user experience. Additionally, we recommend that usability assessments use more than one evaluator to make severity ratings. We found that different evaluators might have different priorities, but by using combined severity ratings from three or more evaluators, you can increase the reliability of the ratings (Nielsen, 2003).

By employing an evaluation processes like the one used in this study to evaluate e-government sites, whether they are G2B sites, G2C sites, or G2E sites, designers and system developers can better allocate limited resources during the design process. In general, it is important that e-government Web site designers take into consideration the demographics of those who will use their Web site or application. If an e-government Web site or application, initially targeted to users with a specific area of expertise, is going to be redesigned for use by the general public, the site must be evaluated for usability. Based on the results of such an evaluation, changes need to be made to ensure that the site is usable by the broadest possible audience.

Chapter 5.8
Quality Enhancing the Continued Use of E-Government Web Sites:
Evidence from E-Citizens of Thailand

ABSTRACT

This study empirically examines Web site quality toward the enhancement of the continued use of e-government Web sites by citizens. The web site quality under examination includes three main aspects, which are information quality, system quality, and service quality. The participants were 614 country-wide e-citizens of Thailand. The data were collected by means of a web-based survey and analyzed by using multiple regression analysis. The findings revealed that the three quality aspects enhanced the continued use of e-government Web sites, with system quality providing the greatest enhancement, followed by service quality and information quality.

INTRODUCTION

Electronic government, so called e-government, has been broadly defined as the use of information and communication technology (ICT) to transform government by making it more accessible, effective, and accountable (infoDev & CDT, 2002). The Internet is indeed the most powerful and popular means of delivering e-government. Hence, Web sites have been employed as a platform for delivering a wide range of government services electronically.

By using e-government Web sites, citizens can conveniently access government information and services and gain greater opportunities to participate in the democratic process (Fang, 2002).

Citizens can access government information and services anywhere and anytime. Thus, the time spent in traveling and waiting is reduced. From the government's point of view, the more citizens that use e-government Web sites, the more operation and management costs are reduced.

To obtain these benefits, the initial adoption and subsequent continued use of e-government Web sites by citizens are required. In general, an information system indicated that its eventual success depends on its continued use rather than first-time use (Bhattacherjee, 2001; Limayem, Hirt, & Cheung, 2003). Likewise, initial use of e-government Web sites is an important indicator of e-government success. However, it does not necessarily lead to the desired outcome unless a significant number of citizens move beyond the initial adoption and use e-government Web sites on a continual basis. To enhance the continued use, this study proposes that quality of e-government Web sites is one significant factor.

According to DeLone and McLean (2002), the three quality aspects, information quality, system quality, and service quality, are the determinants that effect user's intention to use an information system. In practice, these three aspects have been employed to study the initial intention to use the information system and to evaluate the quality of information system (e.g., Lee & Kozar, 2006; Negash, Ryan, & Igbaria, 2003; Wilkin & Castleman, 2002). However, there is a lack of prior research that uses information quality, system quality, and service quality to examine the continued use in the context of e-government Web sites.

This study therefore aims to examine the Web site quality toward enhancement of the continued use of e-government Web sites by citizens. The population of interest for this study is e-citizens of Thailand, a group of citizens who has experienced Thailand's e-government Web sites. The reason that makes Thailand an ideal place to study is that e-government is considered a new innovation to Thai citizens and is conceived as a fundamental element to encourage the country development.

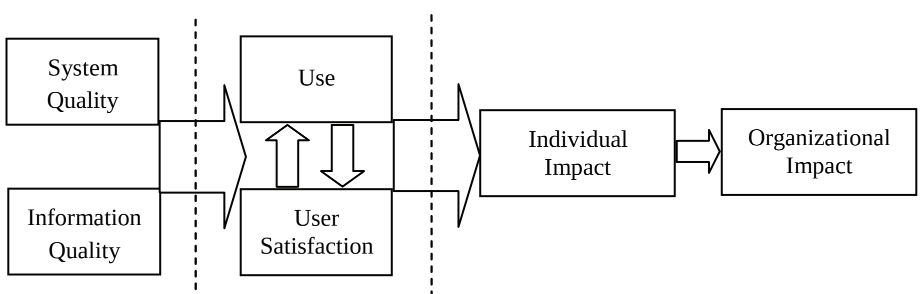
In the next section, the background of this study is briefly reviewed. Thereafter, the research model and hypotheses development, research methodology, and data analysis are presented. Finally, the discussion, limitations, and suggestions for future research are given.

BACKGROUD OF STUDY

DeLone and McLean's Information System Success Model

In order to ascertain the success of an information system, DeLone and McLean (1992) proposed the Information System Success Model (referred hereafter as the 'D&M IS Success Model') as shown in Figure 1. The model asserts that system quality and information quality are the determinants of system

Figure 1. Original DeLone and McLean's Information System Success Model (DeLone & McLean, 1992, p.87)



use and user satisfaction which effect individual and organizational impact respectively.

However, Pitt, Watson, and Kavan (1995) noticed that commonly used measures of information system effectiveness focus on the products, rather than the services. They then proposed that service quality needs to be considered as an additional measure of the D&M IS Success Model. DeLone and McLean (2002) therefore reformulated the D&M IS Success Model by including service quality as an additional determinant that effects the use and user satisfaction as shown in Figure 2.

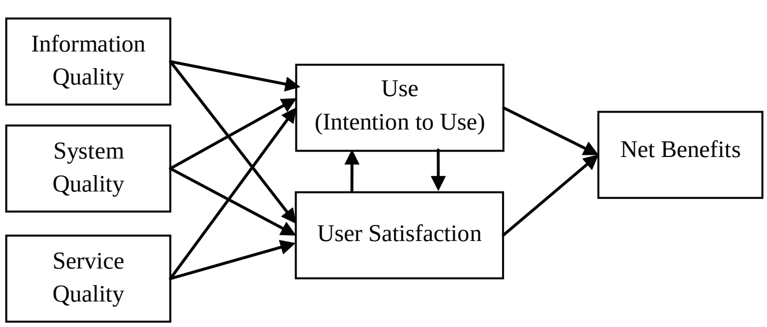
D&M IS Success Model has become popular for the specification and justification of the measurement of the dependent variable in an information system research. In the summer of 2002, a citation search yielded 285 refereed papers in journals and proceedings that referenced D&M IS Success Model during the period 1993 to mid-2002 (DeLone & McLean, 2003). In practice, a number of empirical studies (e.g., Iivari, 2005; Molla & Licker, 2001; Seddon & Kiew, 1994) gave support for the associations among the measures identified in the D&M IS Success Model.

E-Government in Thailand

Like many countries, Thailand has been fully cognizant of both the potentials and the benefits of e-government. Since 1996, the e-government development has been driven by the National Information Technology Committee (NITC). Several programs, such as computer training for mid-level officers, specifying minimum requirements of information technology equipment for government agencies, and the establishment of a Chief Information Officer (CIO) in the public sector, have been imposed to support and promote this initiative (Chamlertwat, 2001). The SchoolNet Thailand (a national school informatization program to empower all schools to access a large pool of information resources using the Internet), Government Information Network or GINet (a government backbone network to facilitate intra- and inter- agencies communication and information exchanges), and the development of legal infrastructure to support the application of information technology have also been initiated under the first National IT Policy Framework for the year 1996–2000 (IT 2000) (Ateetanan, 2001).

In March 2001, the two-year period e-government project was established by NITC to establish a framework for building up e-government and to implement some pilot projects. In March 2002, the National IT Policy Framework for the year 2001–2010 (IT 2010) was approved by the cabinet and e-government was a manifest flagship, in addition to e-industry, e-commerce, e-society, and e-education. Subsequently, in September 2002, the cabinet further endorsed the first National ICT Master Plan for the year 2002–2006. The master

Figure 2. Reformulated DeLone and McLean's Information System Success Model (DeLone & McLean, 2002, p.2974)



plan devises seven key strategies. One of which is e-government (NECTEC, 2003).

As a result, e-government has been developing rapidly in Thailand. In early 2004, NECTEC initiated the first on-line survey of government e-services. The survey revealed that all 267 government agencies have Web sites to provide information to the public (NECTEC, 2005a). With accordance to the global ranking, the E-government Readiness Survey of United Nations (United Nations, 2003; United Nations, 2004; United Nations, 2005) reported that Thailand owned an E-government Readiness Ranking at 56 from 191 global countries in 2003, moved up to the 50th rank in 2004, and finally at the 46th rank in 2005.

In terms of overall usage, there is not much usage of e-government Web sites compared to other Web site categories. According to the Truehits 2005 Award (Truehits, 2006) government Web sites occupied the 15th rank from 19 Web site categories and had proportion of usage only 1.64%, which went down 0.13% from the previous year.

At this stage it is not clear if Thai citizens will continue using Thailand's e-government Web sites. Hence, better understanding of the factors that enhance citizens to continue using e-government Web sites can create greater value for Thailand's government and also other governments all over the world.

RESEARCH MODEL AND HYPOTHESES DEVELOPMENT

Based on the review of the aforementioned literature, the conceptual research model used to guide this study is proposed as shown in Figure 3. The model is based on the three quality aspects of the D&M IS Success Model, adapting to the e-government Web site context. In the following, the meaning of all constructs and the theories supporting the relationships are presented.

Information Quality

According to DeLone and McLean (1992), information quality is concerned with the measure of the information that the system produces and delivers. When applied to this study, the information quality focuses on characteristics of information produced by e-government Web sites.

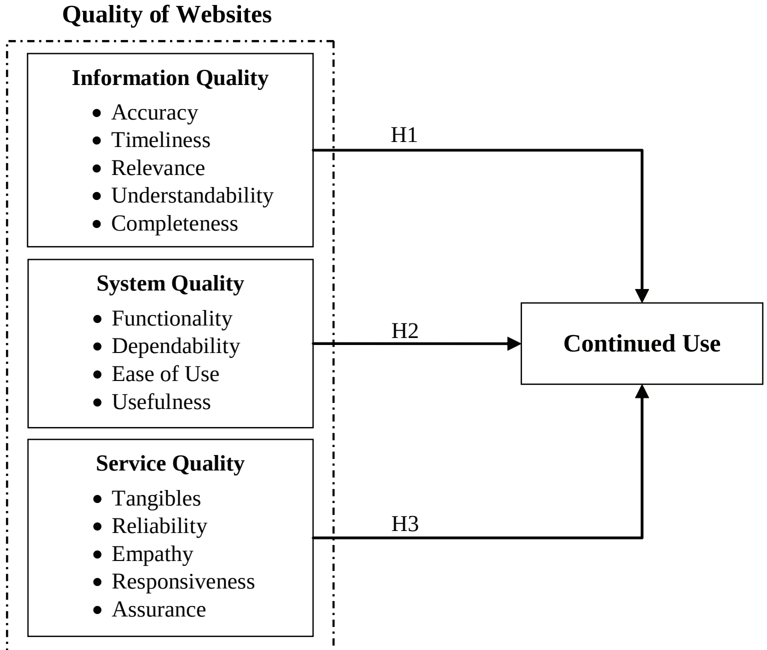
Quality of information is believed to be the most salient factor for predicting customer decision-making behavior (Jeong & Lambert, 2001) and user intention to use a particular system (DeLone & McLean, 1992, 2002; Molla & Licker, 2001). Furthermore, information quality has long been found associated with customer or user satisfaction in previous empirical studies (Seddon & Kiew, 1994; Spreng, MacKenzie, & Olshavsky, 1996; Szymanski & Hise, 2000; Negash, Ryan, & Igbaria, 2003; Iivari, 2005).

Concerning to the case of e-government, the quality of information on the Web sites is very significant since most citizens use e-government Web sites for informational purposes (Accenture, 2004), and the first phase of e-government implementation is to publish government information (infoDev & CDT, 2002). If e-government Web sites contain low information quality, they are useless. Furthermore, high quality information encourages citizens to use the Web sites (Cullen & Hernon, 2004). Hence, the following hypothesis is proposed:

H1: *Information quality of e-government Web sites enhances the continued use of e-government Web sites.*

According to a review of related literature (Bailey & Pearson, 1983; Doll & Torkzadeh, 1988; Wang & Strong, 1996), the fundamental

Figure 3. Conceptual research model



dimensions of information quality is composed of five dimensions: accuracy, timeliness, relevance, understandability, and completeness. This study thereby uses these five dimensions to measure citizens' perceptions toward information quality of e-government Web sites. Table 1 shows a brief definition of each dimension.

System Quality

According to DeLone and McLean (1992), system quality is concerned with the measure of the actual system which produces the output. The system quality in this study therefore focuses on features and performance characteristics of e-government Web sites regarding the quality in use or the citizen's view of quality.

System quality, in the sense of quality in use, has been found as a significant determinant of overall user satisfaction (DeLone & McLean, 1992, 2002; Seddon & Kiew, 1994; Negash, Ryan, & Igbaria, 2003; Iivari, 2005), user acceptance (Bevan, 1999), and system use (DeLone & McLean, 1992, 2002). The more satisfied the user is with the system the more he or she will be inclined to use it. Conversely, if system use does not meet the user's needs, satisfaction will not increase and further use will be avoided (Baroudi, Olson, & Ives, 1986). Therefore, this study postulates that:

H2: *System quality of e-government Web sites enhances the continued use of e-government Web sites.*

Based on a review of related literature (Bailey & Pearson, 1983; Doll & Torkzadeh, 1988), this study identifies and categorizes the characteristics related to the quality in use and user satisfaction into four core dimensions: functionality, dependability, ease of use, and usefulness. Ease of use and usefulness are also excerpted from Davis's (1989) Technology Acceptance Model (TAM). This study therefore uses theses four dimensions to measure citizens' perception toward system

Table 1. Information quality dimensions

Dimension	Definition	Contributing Authors
Accuracy	The information is correct and reliable	Bailey and Pearson (1983) Doll and Torkzadeh (1988) Wang and Strong (1996)
Timeliness	The information is current and timely	
Relevance	The information corresponds to the need and is applicable for the task at hand	
Understandability	The information is clear and easy to comprehend	
Completeness	The information has sufficient breadth and depth for the task at hand	

Table 2. System quality dimensions

Dimension	Definition	Contributing Authors
Functionality	The required functions are available in the system	Bailey and Pearson (1983) Doll and Torkzadeh (1988) Davis (1989)
Dependability	The system is accurate and dependable over time	
Ease of Use	The system can be accessed or used with relatively low effort	
Usefulness	The benefits that the user believes to derive from the system, including convenience, saving time, and saving cost	

quality of e-government Web sites. The definition of each dimension is summarized in Table 2.

Service Quality

Service quality refers to the quality of personal support services provided to citizens through e-government Web sites, such as answering questions, taking requests, and providing sophisticated solutions to citizen's problems. This definition is consistent to service quality of DeLone and McLean (2002, 2004) that concerns the measure of the user support services delivered by the service provider.

Table 3. Service quality dimensions

Dimension	Definition	Contributing Authors
Tangibles	Physical facilities, equipment, and appearance of personnel	Parasuraman, Zeithaml, and Berry (1988)
Reliability	Ability to perform the promised service dependably and accurately	
Empathy	Caring, individualized attention the service provider gives its customers	
Responsiveness	Willingness to help customers and provide prompt service	
Assurance	Knowledge and courtesy of employees and their ability to inspire trust and confidence	

Prior literature on marketing has indicated that service quality is an important determinant of customer satisfaction (Cronin & Taylor, 1992; Bitner, Booms, & Mohr, 1994; DeLone & McLean, 2002, 2004) and repeat patronage (Zeithaml, Berry, & Parasuraman, 1996), especially in pure service situations where no tangible object is exchanged (Parasuraman, Zeithaml, & Berry, 1985; Solomon, Surprenant, Czepiel, & Gutman, 1985). With regards to e-government, service quality is needed since citizens differ in education, knowledge, and experience. The service quality therefore acts as an enabler of the citizen's capability to use e-government Web sites. Hence, this leads to the hypothesis:

H3: *Service quality of e-government Web sites enhances the continued use of e-government Web sites.*

Based on the SERQUAL developed by Parasuraman, Zeithaml, and Berry (1988), the quality of service is composed of five dimensions: tangibles, empathy, reliability, responsiveness, and assurance as defined in Table 3. The SERVQUAL is both a reliable and a valid measure of service quality and is also applicable to a wide variety of service contexts (Parasuraman, Zeithaml, & Berry, 1988). Thus, the SERVQUAL dimensions are used to measure citizens' perception toward system quality of e-government Web sites.

RESEARCH METHODOLOGY

Participants

The participants were 614 e-citizens from five regions of Thailand. The majority of the participants are living in the capital of Thailand (Bangkok) and vicinity (77.36%), followed by the central region (9.77%), the northern region (5.70%), the northeast region (3.58%), and the southern region (3.58%). The dispersion of participants in this study was comparable to the Internet user profile of Thailand, wherein Internet users are concentrated in Bangkok and vicinity, and the rest are distributed in other regions with nearly equivalent proportion (NECTEC, 2005b). Figure 4 shows the participant dispersion in this study compared to the Internet user profile of Thailand.

Demographic characteristics of the overall participants are summarized in Table 4. The proportion of the gender of participants is equal. Most of them are between 21–30 years of age (64.01 %), have a bachelor's degree (54.89%), work in private sectors (58.79%), and have monthly income between 10,001–20,000 Baht (36.64%). About half of participants (62.21%) have experienced Internet for 6-10 years.

In terms of experience with e-government Web sites, the most frequently mentioned experience is searching, inquiry, or complaint (79.32%), followed by online transactions (68.24%) and downloading forms (60.75%). The five most frequently mentioned topics are tax (75.90%), tourism (56.84%), education (55.37%), citizen registration (35.67%) and communication (31.60%). The participants' experience with e-government Web sites is illustrated in Table 5.

Instrument Development

The questionnaire was used as an instrument to gather data from participants. The measurement items for information quality, system quality, and service quality were rated on a 5-point Likert scale (1=Strongly Disagree; 2=Disagree; 3=Neutral; 4=Agree; 5=Strongly Agree). Table 6 lists the measurement items.

The validity of the questionnaire was strengthened through an extensive review of the literature and an agreement among professionals. In addition, the pretest through 25 convenience samples was employed to determine if the intended audiences had any difficulty understanding the questionnaire and whether there were any ambiguous

or biased questions. Based on the feedback of the pretest, one reverse word item was dropped since it caused confusion.

To ensure the measurement items are measuring the same construct, the most widely used measure named Cronbach's alpha was employed for each construct to measure the internal consistency among all items. As observed from Table 7, the reliability analysis gave alpha coefficients exceeding .70 which are typically regarded as an acceptable reliability coefficient (Nunnaly, 1978); one exception was for the scale of completeness which is a little bit lower than .70. However, the lower limit of acceptability may decrease to .60 in exploratory research (Hair, Anderson, Tatham, & Black, 1998). Therefore, the items measuring the constructs were acceptable and reliable.

Data Collection

In order to eliminate costs, data coding time, and human-error, and to easily reach citizens in different geographic areas across the country, a web-based survey with a probability list-based method, which samples participants based on a list, was employed to collect data. The bundled script program was used to check and advise participants, thereby ensuring that all items in the questionnaire were filled in completely and appropriately. To take steps toward ensuring the integrity of the data, the IP address of each participant and the time used for completing the survey were recorded.

After the survey was uploaded to the server, the 3,600 invitations for participation, including a link to the Web site, were randomly emailed to an alumni mailing list in a variety of faculties (e.g., science, agriculture, engineering, pharmacology, liberal arts, business administration, information technology, and humanities) of five universities across five regions of Thailand. The selection of these five universities resulted from a three-stage sampling. First, a stratified sampling was performed to cluster Thailand into five regions. Second, a simple random sampling was done to select a university corresponding to each of the five regions. Third, a simple random sampling was employed to select some email addresses corre-

Table 6. List of measurement items

Construct	Dimension	Description
Information Quality	Accuracy	Using e-government Web sites enables me to have accurate information.
		I can trust the information on e-government Web sites.
	Timeliness	Using e-government Web sites enables me to access the newest information.
		Using e-government Web sites enables me to access up-to-date information when compare to deal with other sources.
	Relevance	Using e-government Web site enables me to have information that is relevant to the site.
		Using e-government Web site enables me to have the information that I need.
	Understandability	Information on e-government Web sites is easy for me to comprehend.
		Information on e-government Web sites is clear for me.
	Completeness	Using e-government Web sites enables me to access adequate information.
		I find information on e-government Web sites is sufficient for the task at hand.
System Quality	Functionality	E-government Web sites provide necessary information and forms for downloading.
		E-government Web sites provide necessary online transactions.
		E-government Web sites provide service functions that I need.
		E-government Web sites present a variety of services
	Dependability	E-government Web sites perform right at the first time.
		Every time I request e-government Web sites, the Web sites are available.
		The government will not misuse my personal information.
		I feel safe in my online transaction with e-government Web sites.
	Ease of Use	I can easily login to e-government Web sites.
		Getting the information that I want from e-government Web sites is easy.
		It is easy for me to complete transactions through e-government Web sites.
		The organization and structure of e-government Web sites is easy to follow.
	Usefulness	Using e-government Web sites enable me to accomplish tasks more quickly.
		The results of using e-government Web sites are apparent to me.
		Using e-government Web sites can cut traveling expense.
		Using e-government Web sites can lower traveling and queuing time.
		Using e-government Web sites enable me to do business with the government anytime, not limited to regular business hours.

continued on following page

Table 6. continued

Service Quality	Tangibles	If I need help, I can find a way to reach a government staff such as email or webboard on e-government Web sites.
		There is staff who will respond to my request indicated on e-government Web sites.
	Reliability	If I send a request via email or webboard to the government, I will receive the right solution from the government staff.
		If I send a request via email or webboard to the government, I will receive the solution that matches to my needs from the government staff.
	Empathy	If I send a request via email or webboard to the government, I will receive the response that shows the willingness to help from the government staff.
		If I send a request via email or webboard to the government, I will receive the response that shows the friendliness of the government staff.
	Responsiveness	If I send a request via email or webboard to the government, I will receive prompt response from the government staff.
		If I have a problem with e-government Web sites, the government staff will quickly resolve my problem.
	Assurance	The government staff seem to have sufficient knowledge to answer my questions.
		The government staff seem to have an ability to solve my problem.
Continued Use		In the future, I would not hesitate to use e-government Web sites.
		In the future, I will consider e-government Web sites to be my first choice to do business with the government.
		In the future, I intend to increase my use of e-government Web sites.

Table 7. Reliability analysis results

Continued Use	3	3.232	.865	.873

sponding to each of the five selected universities. Sending the invitation emails to the alumni mailing list can guarantee that the participants have experience with the Internet and hence probably enabled us to reach e-citizens. In addition, previous studies indicated that e-government Web sites are particularly popular among those who have at least a college education (Larsen & Rainie, 2002; Wangpipatwong, Chutimaskul, & Papasratorn, 2005). Finally, 1,159 e-mail addresses turned out to be invalid and the invitation emails could not be delivered to the recipients. However, there were 2,441 valid e-mails that did reach the recipients.

Responses to the survey were collected for a two-month period (February 1, 2006 to March 31, 2006). Respondents were screened according to whether they had experience with e-government Web sites. Only those who had previous experience continued with the survey. Out of 799 responses, 614 responses indicated experience with e-government Web sites. All these 614 responses were then used in the analysis after they were verified to be valid and complete without any unusual data or multiple responses. The number of valid responses conforms to finite population sampling formula (Yamane, 1973), along with a 95% confidence level and a 5% precision level.

Data Analysis

A multiple regression was chosen as the appropriate method to examine whether information quality, system quality, and service quality of e-government Web sites will enhance the continued use of e-government Web sites. Together with the analysis, assumptions of multivariate normal distribution, linearity, and homogeneity of variance were tested. There were no violations of these

Table 8. Regression analysis results of information quality, system quality, and service quality on continued use

Construct	Unstandardized Coefficients		Standardized Coefficients	t	p	Collinearity Statistics
	B	Std. Error	Beta			VIF
(Constant)	.293	.144		2.031	.043	
Information Quality	.218	.067	.153	3.251	.001	2.371
System Quality	.547	.073	.390	7.515	.000	2.901
Service Quality	.221	.044	.199	5.072	.000	1.660

R^2 = .434; F = 155.793; p = .000

Table 9. Regression analysis results with the finest model

Dimension	Unstandardized Coefficients		Standardized Coefficients	t	p	Collinearity Statistics
	B	Std. Error	Beta			VIF
(Constant)	.283	.137		2.067	.039	
Usefulness	.441	.041	.413	10.826	.000	1.713
Empathy	.179	.042	.179	4.298	.000	2.043
Accuracy	.123	.043	.106	2.846	.005	1.635
Assurance	.105	.043	.102	2.406	.016	2.111
Relevance	.094	.046	.079	2.066	.039	1.715

R^2 = .483; F = 113.514; p = .000

assumptions. The Variance Inflation Factor (VIF) less than 5 confirms the lack of multicollinearity (Studenmund, 1992). Finally, the number of cases is very well above the minimum requirement of 50+8k for testing the multiple correlation and 104+k for testing individual predictors, where k is the number of independent variables (Green, 1991).

ANALYSIS AND RESULTS

To examine the Web site quality toward enhancement of the continued use of e-government Web sites, information quality, system quality, and service quality were simultaneously regressed on the continued use of e-government Web sites. The results revealed that these three quality aspects significantly accounted for 43.4% of the variance in the continued use of e-government Web sites ($R^2 = .434$, $F = 155.793$, $p < .001$). As shown in Table 8, system quality ($\beta = .390$, $p < .001$) yielded the greatest enhancement on the continued use, followed by service quality ($\beta = .199$, $p < .001$), and information quality ($\beta = .153$, $p < .01$). Therefore, all proposed hypotheses were supported.

Afterward, all fourteen dimensions corresponding to information quality, system quality, and service quality were regressed, using stepwise method to investigate the finest model of enhancement. As shown in Table 7, there were five dimensions, usefulness ($\beta = .413$, $p < .001$), empathy ($\beta = .179$, $p < .001$), accuracy ($\beta = .106$, $p < .01$), assurance ($\beta = .102$, $p < .05$), and relevance ($\beta = .079$, $p < .05$) which formed the finest model of enhancement.

CONCLUSION AND DISCUSSION

The aim of this study was to examine the Web site quality toward enhancement of the continued use of e-government Web sites by citizens. The study was motivated by the lack of empirical studies that uses information quality, system quality, and service quality to examine the continued use in the context of e-government Web sites.

As predicted, the results revealed that Web site quality corresponding to information quality, system quality, and service quality enhanced the continued use of e-government Web sites. The higher the level of information quality, system quality, and service quality, the higher the citizens' intention to continue using e-government Web sites. The results thereby corroborate that information quality, system quality, and service quality enhance not only initial intention as DeLone and McLean (2002) asserted, but also the continued use in the context of e-government Web sites.

Further, the results also revealed that system quality provided the greatest enhancement on the continued use of e-government Web sites, followed by service quality and information quality. This outcome resembles e-business study (Lee & Kozar, 2006) that found online customers considered system quality as the greatest significant factor in selecting the most preferred e-business Web sites.

When considering the dimensional perspective, the results showed that there were five dimensions which formed the finest model of enhancement. These five dimensions were ordered in significance as usefulness (of system), empathy (of service), accuracy (of information), assurance (of service), and relevance (of information). This outcome thereby suggests that government should ensure that these five dimensions are well integrated in the e-government Web sites. The following are some of suggestions.

- **Usefulness:** E-government Web site should provide useful services compared to the traditional way, such as convenience, saving time, and saving cost.

- **Empathy:** Responsible staff should give caring and individualized attention to citizen, such as providing individualized attention to individual concerns and requests, through email communication rather than a generic auto-reply message.
- **Accuracy:** Information on e-government Web site should be correct and reliable.
- **Assurance:** Responsible staff should have the knowledge and ability to inspire trust and confidence. The staff should provide impeccable response to convey trust and confidence to citizens.
- **Relevance:** Information on e-government Web site should be relevant to the site and corresponds to the need.

Furthermore, government should obviously disclosure the usefulness of e-government Web sites. The government may highlight the unique features of the Web sites compared to dealing with government staff for the same services and promote the idea that the Web sites facilitate the access to services anywhere and anytime with saving time and cost.

To conclude, it is a necessity for the government to recognize the quality of e-government Web sites, since it enhances the continued use of the Web sites. Government should ensure that the significant dimensions corresponding to information quality, system quality, and service quality are well established. Finally, the next challenge for government involves changing the citizens' perception and the means in which the information, system, and service are presented and delivered to the citizens corresponding to their needs.

LIMITATIONS AND RESEARCH DIRECTIONS

Although the study provides meaningful implications, it has two limitations. First, the dimensions used to measure information quality, system quality, and service quality are equally weighted. Future research may try using dimensions that are unequally weighted. Second, this study intends to elicit data from e-citizens who are ready for e-government. To regard the digital divide, future research should elicit the data from citizens who have lower level of education, lower income, and also citizens who lack access to the Internet.

Tiziana Guzzo
IRPPS-CNR, Rome, Italy

ABSTRACT

This chapter analyzes how the development and use of mobile and Web technologies are changing the way to search information, to plan, to buy, and to travel. The new technologies are changing several aspects of our life, such as the way in which people work, buy, learn, travel, and how they relate to each other, and so on. The tourist sector certainly represents one of the most dynamic markets, able to capture innovations and opportunities provided by the Web, in such a way that gets to be an out-and-out model of e-business. Internet access now is not restricted to personal computer. In fact the use of mobile devices is becoming increasingly important. The chapter's goal is to analyze social implications of Web applications and mobile devices and how they are improving the attitude of the customers both the fruition of tourism services and to development of sustainable tourism.

INTRODUCTION

The widespread use of Internet and Web technology in every aspect of our daily life has brought great change in the consumers habits in any field but mainly in the tourism sector. Every year, million of tourists approach to Internet in order to find tourist information: vacations, flights, guides, last minute, cruises, destinations and routes. This situation is changing the concept of tourism. In particular, tourism was defined by the World Tourism Organisation as "the activities of persons travelling to and staying in places outside their usual environment for not more than one consecutive year for leisure, holidays, business, health treatment, religion and other purposes".

DOI: 10.4018/978-1-60566-156-8.ch027

A new concept of "intelligent tourism" is spreading, based on all those innovative technological solutions offered by Web that allows achieving information on cultural, artistic and other kinds of natural interest.

The Web imposes itself more and more as relevant reference and indispensable resource in the tourism sector both for customers and tourism companies, thanks to undisputed advantages such as:

- Speed for information exchange,
- Improvement of interaction among people located in different places,
- Improvement of information sharing, knowledge and services availability for all the users.

These above three aspects are very important because they are producing the markets globalisation and the spatial and of temporal boundaries break down. Moreover the information and knowledge production and sharing improves both quality development of social inclusion. Moreover, the success of the Web and mobile technologies in the tourism sector is given by very competitive prices, but also by the ability to differentiate the offer, by the improvement of possibility to reach the market niches and by proposing new services with a good usability degree. The user is not a passive subject and when s/he visits a business site s/he knows that s/he will not be able to find negative aspects of a choice. This has brought to the creation of virtual communities where users share their own travel experiences with other tourists and where the potential tourist consumer finds relevant information. The tourist seems in fact to prefer descriptions and testimonies of other people that have already visited that place.

In the next sections we introduce the passage from the old economy to the new economy in tourism sector, in particular we describe how the advent of e-commerce has marked the passage from traditional travel agencies to Internet. In succession we describe the different tools tourist used for Web and mobile and their social aspects. Finally we describe the new scenarios of tourism using the new technologies and how the mobile devices can develop the sustainable tourism, increasing both tourism demand and tourism supply.

FROM TRAVEL AGENCIES TO ONLINE TOURISM E-COMMERCE

The tourism initially involved an elite activity. In the last years it has beenbecoming a mass phenomenon shared by million of people all over the world, and it has been becoming one of most relevant economic sector of most countries. Data provided by World Tourism Council (1997), in fact talk of seven hundred million of arrivals of tourists all over the world. The tourism represents the 7% of the total occupied people and the 2% of global gross domestic product. It is a dynamic phenomenon, mutable and complex, it can be defined as a "social fact", it changes with transition of tendencies, of orientations, of necessities and needs of society.

In the past tourists had to go to the travel agencies, i.e. in the physicals commercial places where to plan and buy a travel. These agencies execute activities of reservation and selling of single tourism services or services packages confectioned by Tour Operators. This means that people, have to go to a physical place to use such services. The choice of the agency can be limited by the physical distance. Moreover services obtained depended by operators, by their personal skills and by their limited information.

When tourists visit different locations guidebook can be very useful. The paper guidebooks more frequency used by tourist in the old economy. Even if they are still now the principal tool used by travellers, because it is easy to consult and information is well structured, they have a lot of limits. Information in tourist paper guidebooks can be outdated because items written many years before could not be updated, hotels and other tourist activities could be ceased (Schwabe, 2005). Actually the new Web and mobile technologies can provide more timely and complete information than paper guidebooks. In fact user can obtain an updated answer to her/his question, more than a paper guidebook and improve the information quality and consequently the travel quality.

Thanks to technology innovation of the last thirty years, not only users have obtained several advantages but also the tourist companies. The most innovative ones in fact, can actually be able to redefine their own organization structure and relationship with partners, optimising the operating costs and improving the quality of services.

Information and Communication Technologies (ICT) have allowed tourism companies to increase their efficiency and their market value. In fact ICT offer the chance to share data-bases with other organizations and other customers' information resources and services. Besides ICT allow to optimize other internal functions, either lowering costs and by expanding services to offer (Poon, 1993).

In latest three decades the tourism sector has been characterized by three technological phases: Computer Reservation System in the 70s, Global Distribution System in the 80s and Internet Revolution since the second half of 90s. (Buhalis, 1998). The first two have allowed to create, to develop and to globalize availability of services by travel agencies, who have exclusive access to automatic booking systems. The last phase has allowed the customer to perform bookings by themselves, redefining the entire business tourism system, modifying the same tourism fruition and improving the tourist experience. (Stipanuk, 1993).

The first change registered in tourism market according to these technological evolutions is a great increase of e-commerce. On-line tourism is one of the most meaningful achievement cases of the e-commerce in the world. The tourism products in fact have ideal characteristics for e-commerce, they can be represented in Web site utilizing potentiality of multimedia and hypertextual communication. Some studious, such as Werthner and Klein, assert in fact, that tourism is considered as one of more important field of application in the World Wide Web.

Some statistic data can help to understand the Internet impact on tourism sector. According to research of Eyefor Travel Research (2007), the tourism e-commerce field represents about the 30% of Web purchases. In 2005 the on-line booking represented the 33,6% of the worldwide tourism market, in 2006 the market quote of travel agencies is of 36,6%, it goes over with the 37,5% by on-line market. However the United States remains on the top of e-commerce for tourism services creating a gap with other countries.

In Figure 1 it is possible to see how the online market is very important and relevant respect to offline market. In Europe the off-line canal is traditionally the one preferred by consumers but it is loosing more and more market quote to vantage of on-line tourism, the online selling since 2002 to 2006 are increased constantly of 43% per annum. Data in the next table is showing the Internet relevance to improve relation between demand and supply operating on promotion and vending of tourism services to consumers. The trend of on-line tourism market (Figure 2), in fact, shows an yearly increase on-going ascent of 30% in 2006 respect to 2005. Among reasons of this increase there are different factors; first of all the raise of Internet utilise, then the coming of low cost companies and last the expansion of large band-width and of electronic credit card.

Analysing the European countries scenario of on-line travel market, United Kingdom is the best one with 34% thanks mainly to large presence of low-cost flight. In the second position there is Germany with 20% of on-line travel market. On the bottom of it there is the Southern Europe, the reason of this gap is also due to socio-cultural factors. The UK consumers in fact, are used to buy everything on the Web, thanks to wide presence of large band-width and frequent usage of

Figure 1. Value of tourism European market: Comparison online offline (Reference: Mele, 2007)

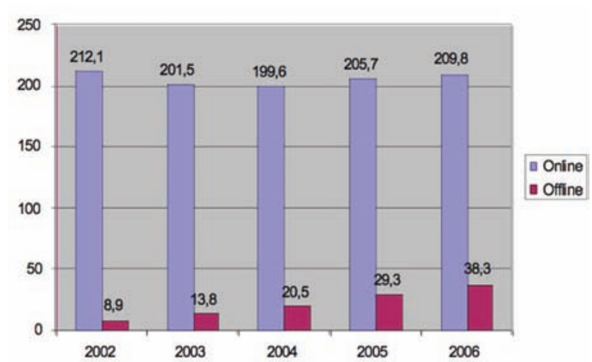

Figure 2. Trend in European online travel market (Reference: Mele, 2007)

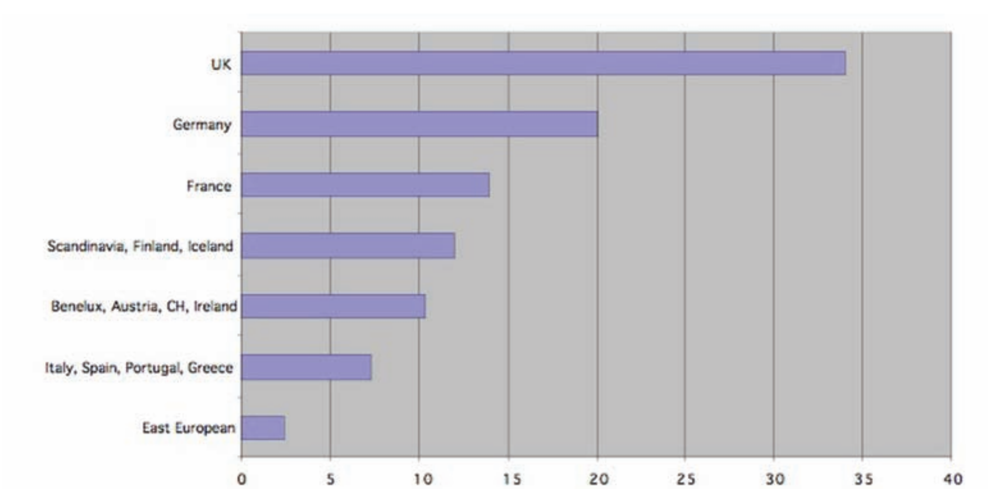
YEAR	TOURISM MARKET (SELLING)	ONLINE SELLING %	ONLINE % SELLING INCREASE
2002	221.036	4,04	77
2003	215.303	6,4	54
2004	220.094	9,3	48
2005	235.017	12,4	43
2006	247.16	15,5	30
2007	253.506	18,4	22
2008	259.723	21,1	17

electronic credit card. In Southern Europe there is distrust to buy in Internet especially by people more traditionalists. There is a cultural distaste to use credit card because they fear to be deceived.

Moreover, there is a short access to the large band-width. It's noticeable that the Web diffusion depends on structural and cultural factors linked to countries' policies and economies. In Figure 3 is represented the European scenario of on-line travel market 2006.

Regarding the service typologies the purchases more frequent on the Web in the European online market are occupied by: Air travel 56%, following booking hotel and travel packages 16%, train 8%, car renting 3% and finally car ferry 1%. Increasing also others segments as holiday houses and cruises. Another data about European scenario is about selling channel: in 2006 the direct sellers

Figure 3. Geographic status of the European online travel market 2006 (Reference: Mele, 2007)



accounted for 69% of online sale and intermediaries the 31%. This is way low-coast companies sells flight tickets directly to consumers by their sites, avoiding intermediaries actions.

The new trend of tourism is also influenced by duration and kind of holiday. In particular short trips, especially in the weekend, are growing. The Online Travel Agencies (OTA) have understood (exploited) this tendency and created the Dynamic Packaging, that allow travellers to organize the travel about their needs.

As reported by travel weekly (www.travelweekly.co.uk) "Dynamic Packaging is the practice of selling holiday components separately rather than in a single package." OTA have to create the Dynamic Packaging to compete with the prices and flexibility offered by online retailers. In general, we can affirm that tourist behaviour shows the wish to adapt vacation to his/her own needs, adopting consequently travel solutions.

The business travel are the most purchased on Internet due to several advantages: convenience, best prices, speed and availability of tools to search travel and services, possibility to change default packages for personal needs, possibility to choice the hotel franchising, the renting society, possibility to read on one page all options about flight and so on.

After to have analysed the transition from offline to online market tourism, in the next section we will describe the new online tools for Web and mobile that improve the quality of tourism services fruition.

NEW TOOLS FOR WEB AND MOBILE INTERACTION

New technologies in hand (at disposal) of tourists have deeply enhanced the tourism information quality. We know that Internet usage is still increasing dramatically, mainly through personal computers and mobile devices. So far, much of this growth has come from new Internet users. Another aspect to consider is that in the short to medium future, users will be accessing the Internet more frequently using a variety of other mobile devices for different purposes and some of these will be quite surprising.

Users can use advanced tools such as wikis, blog, personal spaces, mush-up and their own passage to mobile devices to organise their travels and relate to each others.

Wiki is a Web-based application that allows users to add content and also to edit content supporting collaborative writing, opening discussions, interaction and Web-authoring (Desitlets 2005). At the same time it also allows to delete every content of a new page or another already written by others, to restore an old version, to avoid risks of damages by hackers or non-collaborative members. Thanks to wiki everybody can write everything about a place, a city or a country, and can read everything, or improve what is already written.

Wiki is the most important example of collaborative online community, and applied to a tourism site give to every traveller the chance to share their own experience and to collaborate with other members, activeness and loyalty to the site is guaranteed. The Web site www.wikitravel.org represents an example of a collaborative and updated online global travel guide.

Another kind of Web application important for tourism is represented by personal pages (that can be part of a social network). Technically they are more simple than wikis, in fact they only represent a page created and modified by only its owner. But their technical ease allows users to concentrate on their own contents, and besides they can also build their own buddy network by adding other user's personal pages to their "friend list". Every page becomes in this way an host joint to a bigger network, and every user can discover new paths by starting from the page of a friend. A personal space usually includes blogs: diaries of text or pictures in chronological order (such as Blogspot), personal pages where the contents

Figure 4. Different types of usage of wikis and wikipedia (Reference: White, 2007)

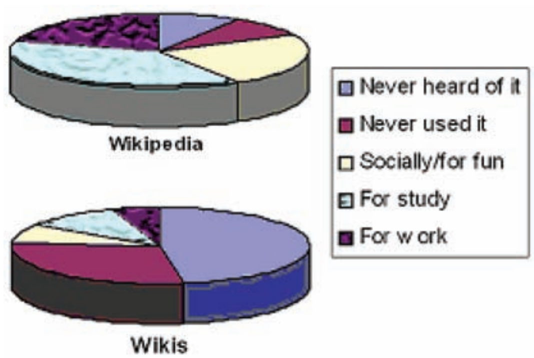


Figure 5. Different types of usage of blog (Reference: White, 2007)

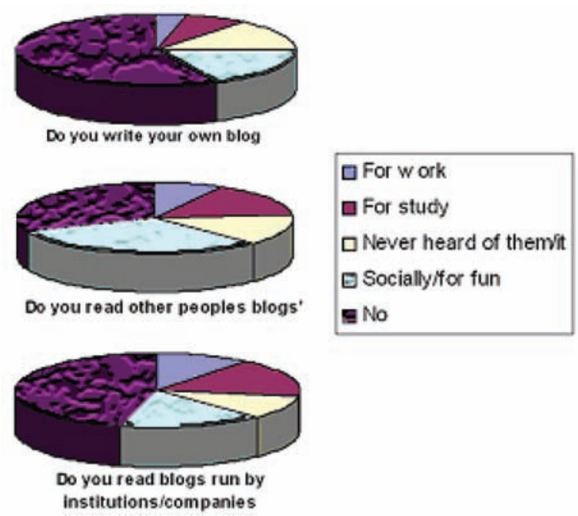


are more static and includes every kind of multimedia items (such as MySpace) or every other thematic social content (list of Web links, list of news, musical tastes, and so on).

It is easy to understand that Internet promotes the making of thematic sub-network such as travel blogs. In the blog every author talks about her/his own favourite topics, and it's easy to quote other's news or opinions in this way; for example, a list of travel blogs links each other to compose a thematic travel network. In fact, new Internet users do not utilize only one tool at time. They use a wide set of Web tools: they write their daily thoughts on a blog, post their best pictures on a photo blog, collect their favourite Web sites on social bookmarks, and so on.. Every kind of new Web application has one special feature that makes the difference among the infinite offer of Internet; however there is the necessity to do not neglect the role of the "pass the word" in the choices of potential tourists. After the vacation, contacts are kept by email and messenger, different opinions are compared on forum, suggestions before leaving are read online, the best offers and discounts are accessible everywhere and every time. In fact, the advanced tools do not swap tools such as emails or forums.

It is important to have an idea about how Internet users relate to wikis and blogs. (Fig. 4-5). About wikis, David White (2007) reports in his research, that most users not know what they are, but when talking about Wikipedia (the famous free encyclopaedia created and continually updated by its users) he reports that nearly the 80% have used it for study, work or simply for fun (see fig. 3). Instead about blogs, users have been asked about their own blogs, other blogs and institutional blogs. What emerged is that only the 20% write their own blog and nearly the 75% read other's blog to work, to study but the most of them is for fun; but if we talk about blogs run by institutions or company the percentage decrease to 45%.

We can easily see that blogs are more used than wikis for fun because they are easier to use and similar to personal diaries then more appropriated to socialise, they are more used by young target under 18 then from 18 to 34 years, less by adult public. Instead Wiky are more complex and reference target is heterogeneous, they are in fact more used for study and for work.

The question is: what does make new Web tools really powerful? This question find its answer in the fact that one of the main goals of Web operator is actually of giving to every content a real meaning; this is the goal of the semantic Web (also called Web 2.0). The simple text of any content over the Internet can always be misconceived by search engine and other Web applications; the goal of semantic Web is giving every object (a picture, a paper, a clip and also papers) a real meaning, and this is possible by linking one or more keywords to that particular object. In this way it is possible for every user to find e.g. pictures of a "puma" without obtaining sport wear brand "Puma" images. The same text, can now have two or more meanings! That's the reason of users' vitality for social networks and new collaborative Web tools, which represent the first step to give texts, pictures, video clip or every other object a real meaning. Moreover, tagging is a new emerging way to categorise, share and search information based on meaning of keywords that facilitate tourists in their choices.

Once contents of every kind are meaningful, becomes important accessing these information and the Web tool that helps user to do that is: RSS (Really Simple Syndication). RSS is a new file format used to communicate information by following a syntax. It is used to spread news, new blog posts and new multimedia object, and it is read by software (Web based or not and also called "aggregator"). Thanks to RSS provided by almost every kind of site, users can read news about their favourite site without visiting every single site. Users can also rearrange their own subscribed feeds to obtain thematic news, by adding labels or tags, the same kind of keywords we talked about Web 2.0. It is easy to understand that the use of RSS allows everybody to improve their own information needs, besides it represents a tool available by every kind of technological device, from a desktop computer or even a small cell phone or a palmtop.

This technology has several positive impacts also for tourism supply. Many companies have adopted RSS feeds in their Web sites to keep a communication with their customers and enhance their search engines optimisation. It is difficult keep update offers and purposes because they are short life. This technology is characterized as a demand-pull rather than a supply push model. (Sigala, 2007). Furthermore, information flows about travels, special offers or more interesting places are real time provided on computer's monitor by a special software (Web-based or not) called "aggregator".

We have already talked about sites that offer the chance to upload pictures, tagging them with keywords (giving these pictures a real meaning), organizing them by creating albums or slideshows; but now the new scenario is about people, or travellers, who can take pictures with digital camera and/or smart phones and immediately send to these to online services. For travellers this means they can prove their skills and their travel experience; for all the other Internet users means to have the chance to find pictures from all over the world, especially when some special happening occurs. This new trend allows old media such as newspaper and television news to report flash news by showing images or video clip, taken from (respectively from Flickr or YouTube).

Another very important field on mobile devices applications for social activities (and consequently for tourists) are organizers and planning sites. They allow to set a calendar of events (to be shared with other users or customers) that can be subscribed, edited and shared. For example Google Calendar allows a hypothetic travel or service agency, to set a special calendar of event about new destinations, prices updates or happy-hour promotion. The users and customers can subscribe this particular calendar, and they can even receive on their own cellular phones SMS reminders that advice about expiring offers or new item added in that particular moment. These mobile technologies make available tools to plan the complete travel and the localization of the places of interest. Among these technologies we find the Internet mapping: the digital interactive maps that supply information on the hotel proximity, restaurants, stores, services, monuments, situated historians, archaeological sites. It is also possible to know the territory classified in different topics (sport, well-being, wine and food, information on traffic, weather forecast). The customer can generate personalized itineraries, search useful services and visualize more specific information on places of interest.

Newer technologies also allow mixing different applications (usually Web-based applications) to each other, to obtain a completely new one with new different functions. These are called "mash-ups", and they represent the newest scenarios in new Web technologies. The most famous mashups are those regarding Google; the Mountain View company in fact, has built a global system of satellite maps covering the whole world, and thanks to GPS devices, users can add new information such as pictures, short videos or information of any kind, exactly relating to a place on the map. In this way tourists can share information of any kind, in a very simple and funny way. Tourists can create their own path by describing with words, by drawing the route on a digital map, by adding digital pictures relating to a special point on the map. So they can create thematic itinerary and share for other tourist, just as every other digital tool we previously described.

Almost every Web 2.0 site involves the chance to interact with the site itself and other users too. The whole Web based application (and so, also online tourism market) is going towards Web 2.0 and so called Mobile2.0, this means that collaboration among users and participation is fundamental for the content site. The future of the e-commerce plays a very important role in the field of the collaboration and sharing: friendships, fellow traveller, socialization are carrying elements of each kind of travel. The main use of mobile devices by tourists is photo and video sharing whit others by personal blog or site.

Portable mp3 devices also give another chance for the tourists. In fact, they allow tourists to bring with them, in a very low weight, a large amount of video or audio files, such as thematic guides. Some operators have also started to provide their customers, with mp3 devices already filled by guides about the subject of the travel (a museum tour, a walk in the historical centre of a town, and so on).

The main reason that allows to tourism to benefit from the use of mobile technologies is the new services to travellers on the move. An example of this technology is the location – based Services.

The term *location-based services* (LBS) refers to information services that are accessible through a mobile handset and based on the current geographic location of the mobile device (Antikainen, H., 2006). The most commonly used is the satellite-based Global Positioning System (GPS). The conventional application areas of LBS include mapping, tracking, routing and logistic, electronic yellow pages, data collection and public safety (Beaulieu & Cooper 2001, Maguire 2001, Veijalainen et al. 2001, Zipf & Malaka 2001).

The primary functions of LBS for tourism are usually regarded as being the localization of persons, objects, and places, search of restaurants, shops, hotels, or points of interest in proximity and information about traveling conditions. Currently, mobile services facilitate the reservation of last-minute trips, rental cars, and hotels; and they provide information about changes and delays of flights and trains, offer guides on restaurants, events, and sightseeing opportunities at the destination (Berger *et al.* 2003, Eriksson 2002).

In the last years mobile devices such as mobile phones with embedded camera, palmtop, notebook and last but not the least GPS systems, have enhanced the use and the production of personal sites and blogs. In fact they allow everybody to post, not only reviews of a new bed & breakfast but also the pictures of the rooms or a short movie showing the landscape.

This brings to birth of the mobile virtual communities. In the next section will be analyse the social aspect of virtual communities.

SOCIAL ASPECTS OF VIRTUAL TRAVEL COMMUNITY

All these new tools that we have described are changing the way of people to interact and to communicate among them. In fact, the users can use these tools and meet new people in a virtual community that is a virtual place where people can speak (textual chat), can meet (video chat), can discuss about different matters (newsgroup and forum), can play and can exhibit themselves (personal home page and free Web).

The first sociological definition of "virtual community" was given from Rheingold in 1993 where he defined the virtual communities as: "… social aggregation that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form Webs of personal relationship in cyberspace. A virtual community is a group of people who may or may not meet one another face to face, and who exchange words and ideas through the mediation of computer bulletin boards and networks".

The first element of a virtual community is the absence of territorial boundaries due to its missing physical dimension; it changes for anyone the perspective to interact with other people according to their own needs and interests enhancing the real interaction and communication possibility. Whatever reason motivates a user to join network, sooner or later, s/he will need or curiosity to interact with other.

The advantage of Web is that it encourages humans to establish "weak" relationship with unknown people; this enables the communication also among persons that have different social characteristics. Moreover the on-line communication usually is uninhibited favouring sincerity in the discussion. The impact in the real social life is not decried but reinforced. The networks represent an aggregation form similar to society in which we live: weak and strong relationship, need comparison and exchange.

This form of social aggregation is not ground on politic, ethnic, linguistic, religious affiliation but volunteer cooperation between individuals that share the same interests, hobbies and goals.

It is easy to understand that Web community has become a term who involves any group of people who communicate online. These people can share different goals, interests or hedonistic pleasures. The term "online community" is also used to mean community network. One of the fields where all these concepts are successfully applied is the online travel community. This is a virtual community where backpackers, globetrotters, and other adventurers from all over the world to join together at different online platforms to exchange information, experiences, and plans in their favorite pursuit travel. In fact, in the travel and tourist industry, Internet encouraged more and more people to join into virtual communities to satisfy their needs, to fulfil their asking tips and suggestion before having a "real" travel.

Recently also travel organizations have realized the power of the new technologies for the core of their activity and the importance of virtual travel communities for their own marketing actions, by broadening their borders.

The travel and tourism virtual communities represent an ideal place without space and time, where people can meet experiences and different worlds. The travel is in its own nature delocalised in respect to point in which oneself is; for this reason it needs a strong communications and information exchange.

The travel experience is rich of emotional and relational contents that for this nature can be shared in the community. A person accesses a virtual community for different reasons: to search information and services, to contact different kind persons, to find partners to share experiences, amuse (oneself). All that is very compatible with tourism that is an "experience reality" and that needs of aggregation places.

Wang, Yu and Fesenmaier (2001) study, analysed needs of online tourists communities related to tourism organization marketing.

They have identified three main classes of needs: functional, social and psychological one. Functional needs include: transaction, information, entertainment, convenience and value. Social ones include: relationship, interactivity, trust, communication and escape among humans. Finally, psychological needs are include: identification, engagement, and sense of belonging, relatedness and creativity. In their work they pointed that since tourism is traditionally studied referring to geography location and space, it is noticeable that tourism-market organizations lack skill in how an online community can be used as a marketing tool. In fact, we cannot forget technological evolution about Internet since the last 15 years. They also predict growing of community concept as the Internet becomes more and more widespread with the new global economy. The network technology has allowed people to be more connected to each other.

People can obtain a lot benefits by joining themselves to the community depending on the different nature of communities and the various characteristics of community members (i.e. many people want to make efficient business transactions and interact with others people; many other rather want to have fun, meet fellow traveller and to express their own opinions; many other still want to develop a sense of belonging, to express their cultural and economic interests and establish relationships).

In 2004 Wang and Fesenmaier expanded their theory with a further study on modelling participation in an online travel community. In particular, were examined the relationship between members' needs and their level of participation in a virtual travel community. In their work they added to the user's needs identified in their previous papers, a hedonic need (including entertainment, enjoyment, amusement and fun). According to them, members participate in on line travel communities to satisfy four fundamental needs: functional needs, social needs, psychological needs and hedonic needs. In this latter work the authors also analyse the role of demographic differences in the behaving of tourism online consumer. It was hypothesized that users' needs in a VTC are not constant but can change with demographic characteristics such as gender, age, education and so on. For example female members usually attach more relevance to hedonic needs, while male members are more significant to membership duration. Other important results of their analysis are about differences according to different ages. For example they observed that groups who are aged 56 or more, versus young members are less attached to functional needs. The aged 20 or younger attribute greater importance than the older groups to social and psychological needs. Differences are also found between members with different education level and their respective needs.

All virtual travel communities have some common features. Communities mostly provide a warm, trusting, and supportive atmosphere. When members share information, they do it with great care and responsibility. They rely on each other more than they do on outdated travel guidebooks or on second-hand and static information from conventional travel literature. They also have to attract a lot of members and give them benefits and satisfactions to be successful. This aspect is very important for tourists because they need to solve a wide range of problems, starting from the pre-visit, the post-visit and of course the travel itself. Before the new technological and digital tools, the traveller could only trust a travel agency operator, but now s/he can find help to choose her/his destination, to solve the most common problems during the planning of the travel (medical suggestions or documents needed), and obviously buying the cheapest flight rate; every question asked by the traveller finds an answer from a user already experienced in that way. But not only, virtual communities are also widely used by tourists to enhance their journey;

in fact as seen before, mobile devices allow users to access the infinite Web without sitting in front of the computer at their home, and heavy guidebooks are now substituted by light mp3 reader or other mobile devices. Finally, tourism virtual communities are important after the travel itself, in fact if a traveller has made use of others' resources, it is now the time to contribute with his own by uploading pictures, writing a review or an itinerary, answering to other's questions, or by simply writing his personal blog to share with friends, but sooner or later someone will find his writing and they will find it useful.

Every user approach a community to search something for himself. This usually is the first step in a lot of other cases, and it is important because the user identifies himself with the community; after this first step her/his loyalty is guaranteed, and it is very easy that s/he will become also a content creator contributing to the growth of the community.

NEW SCENARIOS ABOUT TOURISM AND NEW TECHNOLOGIES

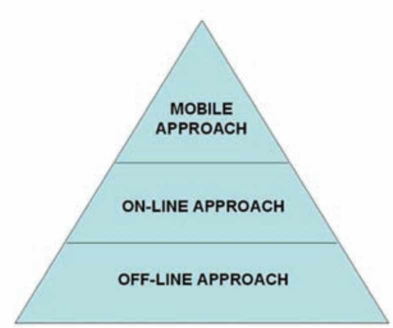
In the early section we analyse the technological and cultural changes trigged by Internet in the tourism fruition and the motivations that encourage the users to belong to a virtual community. All the different modalities used by tourists to plan, buy and do their own vacations, can be classified in off-line, on-line and mobile approach; we can represent them in a pyramid (fig. 5).

The bottom of pyramid is occupied by off line approach; they firstly appeared in chronological order and are the most used by people because they are largely widespread and accessible to the large part of the tourists. Moving upward we find the online technologies more powerful but less widespread and less accessible to users. On the top of the pyramid there are very advanced technological tools (such as mobile devices) but fewer diffused than the other, in fact the pyramid tightens.

It's easy to imagine that in the future this pyramid will probably completely reversed. The traditional paper guidebooks will probably be less utilized and available to tourists while online tools on advanced mobile devices will be largely accessible and commonly used.

The objects in the pyramid of Figure 6 are sorted to help us to simply keep in mind evolution of tourism tools. The basis of the pyramid contains "old economy tools" such as paper guidebook and travel agency. Indeed, they are the most common tools used by travellers, and are concrete objects based on an economy made of selling of products (the paper book itself) or services (travel agency). The next step is represented by the rising of the Web technology; in fact Internet has deeply changed everything, and of course economy too. Everything was concrete in the old economy has now become immaterial and "made of bits". People have Web pages to browse using a computer instead of such a book to read in several contexts. They contain forums, blogs, personal pages and wikis. Then, over the Web era, the top of the pyramid contains technological mobile devices. They are obviously the most advanced tools among the all previously described, and we also have to point that they have to be used jointly with the previous one. In fact, all Web applications will use mobile device so users will have access to information from anyplace and anytime.

Figure 6. Tourism technology evolution



In this way, what we have hypothesized about the future of this evolution (the previously described rotation bottom up) is already in progress, because mobile devices of every kind are used much more than other Web tools. This is causing tourism to benefit from use of mobile technologies about new services to travellers on the move.

Every new technology that we described, can be used to enhance tourist's experience, and they can also be a great chance for local administrations or local tourist promotion organizations to improve their tourism appeal and promotion between appropriate operators.

Mobile technologies give great opportunity to increase the value of territory and to develop sustainable tourism. The virtual community is in fact one of the most effective business models and provides great opportunities for both tourism organizations and customers. (Armstrong & Hagel, 1996).

Users more and more approach to mobile virtual communities to search new and unique contents, uncontaminated places, not commercials and far from mass-tourism. The new tools can allow promoting a sustainable tourism with respect of people and places.

People are searching more and more a high quality environment, but environmental resources on which tourism is based are limited. That's why it is very important to invest in a sustainable tourism. This kind of tourism is defined by the World Tourism Organisation as "tourism which meets the needs of the present tourists and host regions while protecting and enhancing opportunities for the future." A fundamental characteristic of sustainable tourism is that it creates safeguard and respect for the environment and local traditional culture. Moreover it recognizes the centrality of hospitality.

Tourism is a worldwide phenomenon that is very important for the socio-economic development of a lot of countries. It can contribute to the progress of a country but there is the risk it causes environmental degradation and loss of local cultural heritage.

Through digital mobile communication, the natural and cultural heritage that characterize the geographical area, could be communicated in an integrated way to tourist to guide him/her, also by geo-referenced information, toward their own fruition and knowledge with the other purpose, to contribute, through tourism, to the developing of minor tourist centres and their own neighbouring zones. The tourist communication can be made using a Personal Digital Assistant (PDA) or a Smart Phone and thanks to GPS system, it is so possible not only to localize the tourist on the territory, but also the cultural heritage of the location, by sending to users, on their wireless devices, the geo-referenced information with geographic route to reach that particular cultural heritage. The information sent to tourists can be personalized, integrated, complete, clear and multimedia: it can be communicated by text, but also map, video clip, 3D images and audio files.

Social innovations consist of tourists that can reach also places that are not necessarily promoted by tourist book guides or catalogues and they can be reached by messages concerning particular events at the particular time in that place.

Local administrations will have the opportunity, to promote and improve their own territory, to reinforce the sense of belonging and share memories and experiences. The promotion of these cultural aspects of a country will give the chance to have a positive impact on local economies and particularly on the tourism sector.

Promotion of a territory can produce added value to the economy of a place. To promote the local typical products, the local artisan products, to characterize thematic itineraries, fairs, that distinguish a country, is very important to improve the productivity, to create new job and new opportunities and to stimulate the development and innovation. The promotion of a territory is an important moment in the economic development of a community.

Thanks to the use of virtual communities, moreover, local people can enter in contact with people from all over the world and can attract tourists interested in culture and nature of their country.

The use of mobile technologies for sustainable tourism will remove the risk of cultural marginality or isolation because they represent an opportunity for cultural exchange and a possibility to integrate local knowledge into social, economic and cultural development. The importance of natural and cultural safeguarding is confirmed by increased demand of tourism, that joints attention for nature with the interest for intangible culture.

The intangible culture refers to a set of non-physical characteristics, practices, representations, expressions and skills that characterizes cultures, people and places.

The protection and safeguarding of cultural tradition: social practices, typical products, performing arts, rituals and festive events, language, knowledge and practices concerning landscape, has played an important role in the cultural politics and programmes at all levels (local, regional, national, European and international) in recent years. Furthermore people's interest to knowledge and their research of tourism that improves these aspects will remove the risk that a large number of cultural traditions can be lost.

Mobile technologies in the tourism sector represent an important opportunity to improve the vitality of a community. Its bring economic, environmental, image benefits. For example it can stimulate performing of traditional events and festivals that otherwise could be lost. Moreover mobile technologies can stimulate the development of the tourism in marginal regions and can reduce emigration from local areas. They can improve job and earning perspectives of the local population and improve the quality of the tourism activities and the related skills. Moreover they can improve the quality of life of the local population due to the creation of facilities and services, upgraded infrastructure, health and transport improvement, restaurants, food, and so on.

CONCLUSION

In this chapter we explained how mobile technologies have modified tourism sector and how they became important for the tourists themselves and for the global economy.

We have provided a description of the main social implications of the Web technologies earlier, and mobile later. We have analysed how users approach tourism Web applications; they firstly use (for example) Internet to buy low cost flight or to plan trips, later they start writing their blog, sharing their pictures or reviewing their trips, and in this way they start contributing to build a virtual community that will be used by other users for advices to buy their tickets, to plan or share their trip or just for fun. That's why all this, is now called social network.

The next step we have analysed is the coming of mobile devices that have revolutionized the way that tourists enjoyed their experiences. In fact, it is obvious that Internet, as described above, helps tourists before and after their trips, but now, thanks to mobile devices, the high potential of Internet is brought straight to their hands to facilitate the fruition of tourism. Mobile technologies can improve accessibility, information and service provisioning and safety for both tourists and tourism resorts.

Then we have hypothesized a pyramid representing on the bottom the old economy of a travel agency or a paper guidebook, in the centre all the new economy tools belonging to the Internet world, and on the top the mobile devices. Anyway analysing the future scenario we have also described the rotation of the pyramid because in the near future mobile devices will be more accessed and utilised than old economy tools, and what was rarely diffused in the past, will be commonly used.

Finally we focused on the issue of sustainable tourism a new way to travel respecting environment and traditions, by merging information sharing and new technological devices.

Thanks mobile devices several small places and particular events far from commercial routes can be promoted by local administrations and discovered by tourist, contributing both sustainable tourism and development of small place's economy.

KEY TERMS

Mobile Interaction: The relation between users using mobile devices, it allows users to communicate and to access Web applications from any place.

Mobile Technologies: A parent category for mobile telephony, mobile computing, and miscellaneous portable electronic devices, systems, and networks.

Online Tourism: The purchases, the selling or the consultation about services tourism on Internet, both Web and mobile technologies.

Social Network: A community of people who share interests and activities, or who are interested in exploring the interests and activities of others. Each user create contents and uses others' contents.

Sustainable Tourism: A tourism which meets the needs of the present tourists and host regions while protecting and enhancing opportunities for the future.

Virtual Travel Community: A group of people that primarily interact via communication media such as forum, blog, chat room, instant messaging and that are interested in sharing information about tourism or travel.

Web Interaction: The relation between users and Web applications in order to search information about their own needs or for fun.

Chapter 5.10

Healthcare Quality and Cost Transparency Using Web-Based Tools

Jiao Ma
Saint Louis University, USA

Cynthia LeRouge
Saint Louis University, USA

ABSTRACT

This chapter explores the use of Web sites to provide patients with understandable information about the quality and price of healthcare healthcare transparency). Our first objective is to discuss patients' perceptions of empowerment and need for quality and cost information when choosing medical providers and facilities for healthcare procedures. To meet this objective, we address issues of patient awareness of sources of healthcare quality and cost information, perceived responsibility for managing healthcare costs, and knowledge of appropriate actions to exercise choice of providers. Our second objective is to investigate the potential of Web-based tools, which provide healthcare quality and cost information, to facilitate patients' decision-making processes regarding choice of provider for healthcare services, particularly common outpatient procedures. To meet this second objective, we use insights from user-centered design procedures (e.g., focus groups and in-depth interviews) associated with the development of a healthcare transparency Web-based tool.

DOI: 10.4018/978-1-60566-016-5.ch011

INTRODUCTION

On May 10, 2006, Carolyn Clancy, M.D., Director of the Agency for Healthcare Research and Quality, testified before the Joint Economic Committee of the U.S. Congress outlining the commitment of the Department of Health and Human Services (HHS) to provide Americans with understandable information about the quality and price of healthcare. This vision has four objectives:

- Promote quality transparency;
- Promote price transparency;

- Facilitate the greater use of health information technology; and
- Transform healthcare so its incentives support a consumer-oriented healthcare system.

The synergy of these objectives is an informed and empowered healthcare consumer with a panoramic view of his/her healthcare situation.

The Internet has done much to facilitate this view by providing an ever-expanding bounty of information about health prevention and maintenance; however issues such as the general understandability and accuracy of this information still remain. Interactive tools and features that provide communication channels (e.g., peer support groups) and personalized information are increasingly common supplements to content pages. Monitoring devices have also been an area of great advancement and promise.

It is evident that patients have an appetite for prescriptive and preventative healthcare information and tools. However, does this need also exist for healthcare cost and quality transparency? The first objective of this chapter is to better understand patients' perceptions of empowerment and need for procedure quality and cost information when choosing medical providers and facilities. The second objective of the chapter is to address the potential of Web-based tools to facilitate and enable the patients' decision-making processes. To meet these goals, questions of interest include:

- Do patients perceive quality and cost information as important to their choice of healthcare provider?
- Do patients feel empowered with quality and cost information to make decisions about where to have medical procedures (e.g., mammogram and bone density tests) or tests (e.g., spinal tap or allergy testing) performed?
- Would a Web-based tool that provides quality and/or cost information be compatible with the patients' decision-making processes?
- What factors should be considered in designing a useful and usable Web-based tool to provide quality and/or cost information for patients?

We review existing literature, assessment of existing healthcare transparency Web applications, and insights from user-centered design techniques from an on-going study involving developing such a tool to reveal issues, controversies, and problems associated with healthcare quality and cost Web-based tools, and discuss solutions. We adapt the constructs from a Theoretical Compatibility Model (Karahanna, Agarwal, & Angst, 2006) to use as thematic dimensions to organize our presentation of Web-based quality and cost tool compatibility, as well as provide insight within the landscape of existing information systems research.

BACKGROUND

In America's democratic consumer culture, consumers can easily obtain information about price and quality for most purchases using existing resources (e.g., mass media such as TV, print publications, Web sites) to assist with purchase decisions. A noted exception is healthcare where cost and quality information is still limited (Greenberg, 2006). In a consumer-driven system, healthcare buyers with financial incentives will demand quantitative and qualitative information on competing health plans, facility options, providers, and specific healthcare treatment. Plans and providers will be motivated to supply this information in order to manage cost and utilization as necessary to stay competitive.

Healthcare transparency is about disseminating information (quality and cost) in a patient-friendly manner to allow patients to make informed healthcare decisions based on value. Ideally, transparency creates incentives at all levels and motivates the entire system to provide better care for less money (HHS, 2007). Providers will improve when they see how their practices compare to others, and consumers benefit from making informed decisions. Additionally, it is theorized that healthcare transparency will encourage patients to become better healthcare shoppers by factoring quality and price into decisions about care, which will lead to a positive impact on management of healthcare costs at both individual and industry levels (Openshaw, 2006). It is through these ideals that some embrace healthcare transparency as an element in change and reform in America's healthcare system (Greenberg, 2006). A modern healthcare system and a democratic consumer culture demand a modern information strategy (Lansky, 2003).

The Internet plays and will continue to play a key role in consumer research, plan enrollment, ongoing administration, and customer service (Beauregard, 2006). According to Coulter (2005), alternative ways of accessing health advice are becoming more popular. For instance, a recent UK survey of people aged 45 and older found over 30% of respondents had searched for health information on the Web. In addition, the Agency for Healthcare Research Quality (AHRQ) recommends a wealth of Web-based resources for healthcare quality information and tips, as well as print resources (AHRQ, 2007) to assist consumers in making more informed healthcare decisions. As such, emerging Web-based tools and resources are a logical choice for providing patients with healthcare quality and cost information—for example, CompareYourCare hosts 22 tools (including three English/Spanish bilingual tools) that compare and rate the quality of healthcare, according to national treatment guidelines, and assist self-care by providing up-to-date information and skills to better manage an illness or maintain good health (http://www.compareyourcare.org/). This site was developed by the Foundation for Accountability (FACCT), and is owned by HealthGrades Inc. Among the efforts of making healthcare more "transparent," a handful of states like New York, Florida, Maryland, and Texas provide state-sponsored Web sites (e.g., New York State Healthcare Report Card at http://www.abouthealthquality.org/index/about) which enable patients to compare hospital and, physician prices (a range of charges or average prices) and performance.

The aforementioned states are using this type of "transparency" to force poorly performing providers out of business and push providers at the high end of the spectrum to voluntarily lower their fees (Lemov, 2006). Hospitals were found to respond positively to public reporting by immediately improving their quality scores during the preparation of disclosing quality data. Most of the hospitals were able to spot their failings from site information and changed policies as appropriate to meet the standards.

The objectives of these sites are not only to prompt organizational action, but also to influence patients' decision-making behavior. Site information about the cost and quality of care is offered to patients to accommodate their higher responsibilities in paying and managing healthcare costs. However, despite the free and easily accessible data, little empirical evidence has shown that patients have altered their behaviors in response to publicly reported quality or cost measures (Lemov, 2006). In fact, there is little elaboration on patient issues related to cost and quality transparency. Furthermore, there is no clear indication that patient input was considered in creating the design and content of these sites. Hence, this chapter focuses on trends, issues, controversies, and solutions for using Web-based tools to provide healthcare transparency from the patient perspective.

TRENDS, ISSUES, AND CONTROVERSIES

Quality and Cost in the Healthcare Decision Process

Do patients perceive quality and cost information as important to their healthcare provider decision-making process?

Service marketing literature indicates that customers attempt to evaluate both functional quality (i.e., delivery quality, which includes an assessment of reliability, responsiveness, assurance, empathy, and tangibles) as well as technical performance quality in deriving quality judgments. However, the entire quality judgment will be made on delivery quality elements, if someone lacks the ability to assess technical quality (Gronroos, 1984). In reference to healthcare, Bowers and Keife (2002) pointed out that functional quality traditionally has received more weight, because patients often lack the technological sophistication to understand details of their diagnoses and treatment and place paternalistic trust in their physicians to make the right decisions.

However, times are changing. The 1996-2000 FACCT study on patients and healthcare quality found that patients are beginning to seek outside information and use it to ask questions of their healthcare providers and participate in healthcare decisions (FACCT, 2000). About one-third of the patients in the FACCT study used the Internet for seeking health information. When selecting a physician, the FACCT study found that patients were interested in factual information, such as years in practice, malpractice record, hospital affiliation, and so on. About 28% of those studied accessed Web sites to read and post messages about a physician. Segmentation of the adult population in the FACCT study suggests that the most passive healthcare participants are older men with lower than average incomes with at least one chronic condition, while the most aggressive information seekers are women with higher-than-average incomes.

Recent trends also show a shift related to healthcare costs. American healthcare is moving toward consumer-driven health plans, which require significant copays or deductibles and/or utilize personal flex spending accounts (these accounts allow participants to allocate limited amounts of pre-tax dollars to cover healthcare costs). As early as 1986, Rosenstein (1986) called attention to the trend in making patients more financially responsible for medical care services by increasing their out-of-pocket costs. For patients with consumer-driven plans, cost is an important factor. In fact, Rosenstein predicted that cost will eventually become one of the major criteria used in healthcare selection. In response to patients' increased concerns regarding costs, changes in healthcare are under way. For instance, walk-in retail clinics, which target providing convenient access/limited service at a competitive price, are spreading nationwide. More than a dozen clinic operators plan to open thousands of clinics in stores such as Wal-Mart, CVS, Walgreen's, and Kerr Drug. Prices at these walk-in clinics are posted on an electronic sign as in a fast-food restaurant (Schmit, 2006).

Cost and quality information are not separate issues, but are intertwined in making an assessment of healthcare value. In a national survey of healthcare consumers in Taiwan on patient perceived quality and expensiveness, Cheng, Wei, and Chang (2006) found that patients indicating higher perceived quality (i.e., physician technical or functional interpersonal skill ratings) were less likely to report that charges were expensive. Using consumer cost theory, this study concluded that perceived value rather than the price or quality alone is the essence of competition in the healthcare market. Hence, when the quality of the healthcare services meets a consumer's expectation and the consumer considers the price to be worth the anticipated quality, then consumer satisfaction emerges and consumption of those services continues.

Consumer Empowerment

Do patients feel empowered with cost and quality information to make decisions about where to have medical procedures performed?

The traditional paternalistic approach of decision-making in healthcare assumed that (1) doctors and patients shared the same goals; (2) only the doctors were sufficiently informed and experienced to decide what should be done; and (3) patient involvement would be limited to giving or withholding consent to treatment. Evidence shows that higher engagement of patients in decision-making and active involvement in managing their healthcare leads to more appropriate and cost-effective use of health services and better health outcomes (Coulter, 2005). Consumer empowerment includes consumer activation and public disclosure of performance information (Bethell, 2000). Consumer activism refers to patients proactively seeking information about healthcare, health, quality, and cost (e.g., looking up information about a new prescription such as precautions and side-effects). Public disclosure refers to a critical mass of patients having timely access to relevant and understandable information about healthcare performance (e.g., obtaining information on healthcare professionals' backgrounds before agreeing to see them).

When it comes to quality and cost information, the healthcare industry has been described as an imperfect competitive market of uncertainty and information asymmetry (Cheng et al., 2006). This asymmetry impairs patient empowerment in the decision-making process. Healthcare might be the only industry where a consumer can walk through the door, obtain a service not knowing how much it costs, and walk out without paying. This point is highlighted by a recent study, which found patients were able to guess the price of a Honda Accord within $300 and estimate the tab for a coast-to-coast round-trip airline ticket within $37, but were off by $8,100 for a four-day hospital stay (Howley, 2006). Hence, public disclosure of healthcare quality and cost information provide information that is not presently known. This additional information may empower consumers to exercise judicious choices in healthcare decisions, such as where to have medical procedures performed.

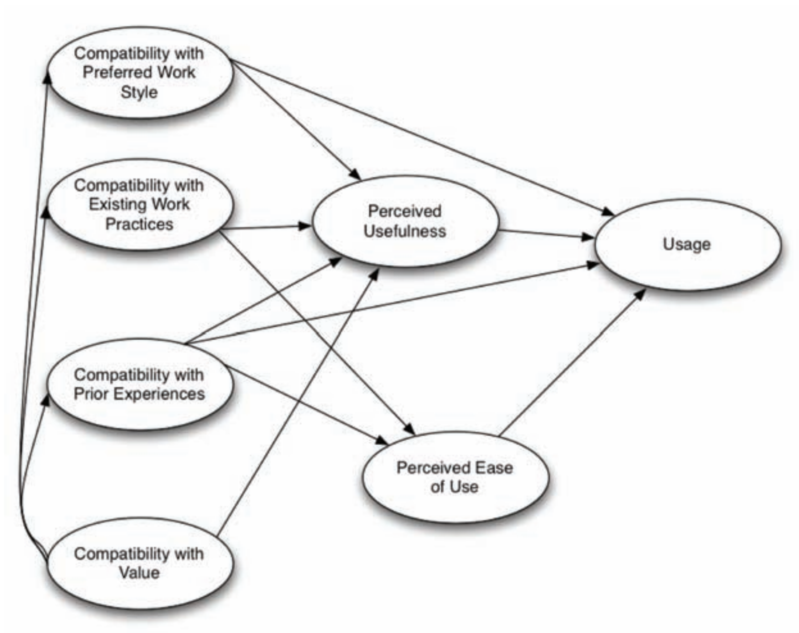
Web-Based Quality and Cost Tool Compatibility

Would a Web-based tool that provides quality and/or cost information be compatible with the patient's decision-making process?

While the trend is toward patient empowerment and healthcare information seeking, the question of compatibility between a Web-based tool and the patient's decision-making process is not yet sufficiently answered. Compatibility is a multi-faceted issue. Two general aspects of compatibility are normative/cognitive compatibility (referring to feelings or thoughts) and operational compatibility (referring to the compatibility of an innovation to what people do) (Rogers, 1995; Tornatzky & Klein, 1982). With respect to cognitive compatibility, patients' thoughts and feelings on how cost information factors into their healthcare decision model need to be considered. If cost information is not currently a major factor, a key challenge in controlling costs through cost transparency will be how to best reframe patients' thinking about cost as a decision factor. With respect to operational compatibility, the propriety of a Web tool used for this purpose and its design need to be further considered. Recent work in the information systems domain further breaks down operational compatibility into compatibility with preferred work style, existing work practices, and prior experience, as well as elements of technology acceptance (Karahanna et al., 2006).

There is little evidence in research, and to some degree in practice, to determine whether

Figure 1. Theoretical compatibility model (from Karahanna et al., 2006, pp. 789)



providing healthcare quality and cost transparency via the Internet is compatible with patients' existing needs and preferences. Compatibility in this context is complicated by the issues that what is deemed as relevant information is situational to patients (e.g., specific insurance coverage or health condition). The information infrastructure needs to offer information that people want, and distribute it when and where they need it. In addition, the information delivered by a Web-based tool needs to be personalized to meet each patient's and family members' specific needs (e.g., health needs, language, culture, information seeking behavior) (Lansky, 2002).

To begin to explore the compatibility issue, we adapt the compatibility antecedent constructs from the Theoretical Compatibility Model (Karahanna et al., 2006) to use as a dimensional (thematic) framework to disclose potential compatibility issues. Figure 1 shows the model from the Karahanna et al. study; the model exhibits some statistically significant relationships, along with theoretical relationships proposed for "compatibility with existing practices" that could not be tested. We use the adapted model as a priori prescriptive framework, as opposed to an assessment of a completed innovation in the previous research.

Table 1 provides a comparison of compatibility construct definitions used in the previous study with those used in this study. Some adaptation of construct definition is needed to suit the context of patients' volitional use of a Web-based tool. In the forthcoming section, we propose this model as a way to inform future design and acceptance of an innovation.

PATIENT COMPATIBILITY: CONSIDERATIONS TO ENHANCE EASE-OF-USE AND VALUE

What factors should be considered in designing a useful and usable Web-based tool for providing quality and/or cost information to patients?

To address the final question of interest, we continue the discussion using insights from user-

Table 1. Comparison of construction definitions between Karahanna et al. (2006) and current study constructs

Karahanna et al. (2006) Construct	Karahanna et al. (2006, pp. 787) Definition	Current Study Construct	Current Study Definition
Compatibility with Preferred Work Style	Captures the possibility offered by the technology of being consistent with a desired work style	Compatibility with Preferred Task Style	Patient's self-concept regarding the functionality (way) they would like to explore healthcare cost and quality information; cost and quality functional requirements
Compatibility with Existing Work Practices	Measures the extent to which a technology "fits" with a user's current work process	Compatibility with Existing Task Practices	Current practices patients use to find cost information or information seeking strategies used to find health information on the Internet.
Compatibility with Prior Experience	Reflects a fit between the target technology and a variety of users' past encounters with technology	Compatibility with Prior Experience	Existing knowledge or perceptions of fact regarding cost/quality information and experience in using healthcare cost comparison sites.
Compatibility with Value	Epitomizes the match between the possibilities offered by the technology and the user's dominant value system	Compatibility with Healthcare Cost and Values	Patient's dominant value system that affects factoring of healthcare cost and quality into healthcare decisions.

centered design procedures associated with the development of a particular healthcare transparency Web-based tool (sponsored by a healthcare insurer). We provide insights regarding patients' preferred task styles, existing task practices, prior experiences, and values to use as considerations in developing a transparency tool compatible with the patient perspectives. Insights from these procedures are not intended to draw final conclusions, but to inspire further work in research and practice in meeting patient healthcare quality and cost transparency needs through the use of Web-based tools.

User-Centered Design Methods

The user-centered design (UCD) methods that were used include focus groups and in-depth interviews (IDIs in-depth interviews (IDIs) with primary target users. Participants for both the focus groups and IDIs were randomly selected from a consumer sample provided by a professional marketing firm. The following selection criteria were used to define the sample:

- A variety of group and individual health insurance plans were represented
- A mix of males/females
- Variety in the age range between 18–55 years
- Participants were involved in, or responsible for, household healthcare decisions
- Insurance customers with an annual deductible under $500 and those with an annual deductible in excess of $500
- Participants were computer and Internet users

Members of the pool were assigned to either a focus group or an IDI. Two focus groups were conducted with the potential users of a Web-based tool. Each focus group consisted of eight-to-ten participants and lasted approximately one and one half hours. One focus group included insurance customers with an annual deductible under $500, and one group with an annual deductible in excess of $500. An experienced moderator and a panel of analysts conducted and analyzed the focus groups, respectively. Appendix A provides a general outline of the protocol used to explore beliefs and attitude structures related to healthcare transparency and the use of a Web site to provide this transparency. Exact questions and the flow of conversation evolved around the topics to best suit the characteristics and flow of the groups.

Twelve people participated in IDIs individually. IDIs are a nondirective, qualitative type of interview with an emphasis on listening to people talk in response to a minimal number of specific questions, which are primarily open-ended (Miller & Crabtree, 1999). This research technique provides value through qualitative insight into the belief and attitude structures, which may be used, particularly in business contexts, for strategy development. The IDIs were conducted by a professional interviewer and each lasted approximately 45 minutes. The objectives of these interviews that guided the discussion were: (1) to examine reactions to the concept and design of the Web-based tool, and (2) to extend exploration of focus group topics regarding healthcare transparency beliefs and attitudes. The IDIs began with a discussion of beliefs particularly related to cost transparency and migrated to concept evaluation. Projective techniques were used during the IDIs to allow respondents to engage in free-flowing and creative descriptions of their healthcare cost and quality information needs and how to meet these needs using the prototyped Web-based tool. The concept discussion was followed by a prototype review. The prototypes used in the IDIs were high-fidelity mockups of screen designs, which were a lifelike simulation of the final product with a refined graphic design. However, the back end of the product was simulated rather than real (Isensee & Rudd, 1996).

The Theoretical Compatibility Model in Figure 1 was used as a coding scheme for organizing insights from the investigation using the UCD techniques into compatibility dimensions. Two researchers participated in the coding process and worked together to reach final coding consensus.

Preferred Task Style

To make a decision on the choice of a provider or facility, the UCD data indicated that patients need quality information to accompany cost information, which aligns with the previous discussion of value. When it comes to quality information, participants stated they wanted performance metrics for the healthcare facilities. For cost information to be useful, it must be specific. In other words, participants indicated that patients need explicit and accurate cost information for obtaining the procedure of interest at specific facilities, instead of an average or a range of costs. Hence, the ability to specify parameters within the Web-based tool to customize information to individual situations is important. For example, some participants indicated they liked to be able to calculate their "out-of-pocket" costs based on their individual plan benefits. To meet this need, a calculator to determine "out-of-pocket" cost is an appropriate feature. As another example, some patients want to limit their search to facilities within a specific driving distance.

Multiple sources of data enhance usefulness, particularly regarding quality. To illustrate, some participants expressed an interest for a health transparency Web tool to include links to facility Web sites for further research regarding quality. In addition, people who have undergone similar procedures were considered as a valuable source of information. This was expressed by the desire for online discussion groups and other forums to communicate with other patients. As another alternative, a simple star ratings system was recommended to provide patient feedback for each facility that offers a specified procedure.

However, the UCD data recommended avoiding situations in which patients drown in data and cannot make use of the information. Healthcare cost information must address specific information needs, in order to be useful and meaningful to the patients. Participants mentioned the following factors, which need to be considered in specifying meaningful data regarding healthcare quality and cost transparency:

- Type of service anticipated by the patients
- Specific hospital/clinic providing the service
- Insurance carrier or coverage medium of the patient
- Benefit plan of the patient (deductible, co-insurance, out of pocket limit)
- Procedural information about procedures (such as side-effects and recovery time) is desirable and should be presented with intuitive graphics and imagery where possible.

In seeking to affect patient behavior, entities offering such tools should consider that the Web tool alone might not be enough for a patient to finalize a decision. Participants indicated a Web-based tool should afford users the opportunity to have personal contact via telephone with a "live person," either during or after using the site for questions, or to call a facility for confirmation once they have narrowed down their choices.

Compatibility with Existing Task Practices

The Web-based tool should function in a way that matches patients' natural information seeking behavior. This corresponds to the fact that the user interface needs to be intuitive, informative, and visually appealing, as expressed in various ways by participants. In reviewing UCD data to affirm these generalizations with specific examples, search, sequencing, and support considerations were mentioned.

A desirable search function should generate only effective and "on target" returns. In inquiring what patients may search for, the indication was that patients would seek information to better understand a specific procedure or learn more about a facility beyond the cost information for a procedure of interest. The name of a facility or procedure would be a common search parameter. Regarding the sequencing of information, proxies for quality or general descriptive information (e.g., bed counts, nursing care information) about a facility must be provided before patients can utilize the cost information in their decision-making processes, again aligning with concepts of value using consumer cost theory.

Support services in various forms are an existing practice with many technological tools. Like most users of complex information technology, healthcare patients feel most comfortable knowing a support person is available to help them, in case they encounter problems with the Web tool or have additional questions.

Compatibility with Prior Experience

Utilization of health transparency Web-based tools is a new experience. In recognizing this, participants indicated that public relations and marketing efforts are a must to promote awareness and, most importantly, the value of a health transparency Web-based tool.

Earlier in this chapter, we discussed the general information asymmetry that currently exists, that patients are not well informed regarding healthcare costs, and generally do not know where to look to find this information. Given this asymmetry, patients have little to no experience in accurately estimating healthcare costs and tend to make inaccurate estimates of the costs (Howley, 2006). The UCD data indicates patients may not only be unaware of a specific price or range for a procedure, but that patients may also be unaware that different facilities can have different costs for the same medical procedures or treatments (e.g., colonoscopy). In addition, even if armed with information regarding cost differences, participants doubted that they were empowered to select a facility for medical procedures. Many believed this decision was completely under the control of the physicians. If health transparency tools are to affect behaviors, the lack of knowledge regarding the patient's role in the decision process needs to be remedied through patient education. As such, health transparency Web tools may include such content as "next steps," "how to compare," or "discussing costs with your doctor."

Compatibility with Values

Consumer attitudes and expectations about healthcare are shifting toward increased clinical performance and public accountability. Some patients have become activists who demand and use information about medical treatments, healthcare products, and healthcare standards (Kizer, 2001).

On the subject of healthcare standards for a Web tool, participants indicated concern about the source of the information. Patients demand impartial and credible sources to help with their decisions. The Web tool prototype that participants reviewed during the IDIs was sponsored by a health insurance carrier. Remarks regarding the sponsorship indicated that trust in insurance carriers was generally low among the participants. Many participants believed that carriers bear the responsibility for healthcare costs, and hence, are driven by a "profit motive." Consequently, concerned participants suspected that data provided by the carrier might be biased toward increasing a carrier's profit. To offset perceptions of biased data, there were recommendations to add information provided by credible sources, such as independent ratings of facilities and providers. Examples given included performance metrics, backgrounds, customer evaluations, and activity information (e.g., annual numbers of services performed) for both physicians and facilities.

Regarding the decision process, the UCD data revealed that patients predominantly based their choice of care decisions on the quality of the physician performing the procedure, which is measured using three criteria: (1) past experience with that physician, (2) the physician's reputation and specialization in that procedure, and (3) recommendations of others (e.g., family and friends). The obvious caveat relative to this chapter is that the cost of a medical procedure is not currently a primary factor that patients consider when making decisions regarding personal or family medical procedures.

Part of the emphasis on quality is attributable to minimizing health risks. Participants pointed out that healthcare service was viewed differently from other professional services. Specifically, they indicated some healthcare procedures (e.g., a life-threatening surgery) could not be viewed as commodities. It was also expressed that when it came to a loved-one, particularly a child, even if a procedure was "simple," the focus was quality. Consequently, patients do not view these types of healthcare decisions as potential "shopping" experiences. Also, participants expressed that they had less desire to control costs than with other types of purchases. One focus group participant stated, "Healthcare is perceived [as] too important to be considered as a shopping experience." Participants indicated that they are more likely to research cost information on the Internet for autos, electronic products, and other types of professional services (e.g., funeral, legal service) than they would be for healthcare cost information.

The other reason for concentrating on quality in the healthcare decision process is attributed to the fact that most consumers are not paying directly for medical procedures, whereas they are for other products. Furthermore, patients often feel entitled to insurance coverage or some other form of cost coverage. Participants disclosed a long-standing perception that healthcare costs are someone else's problem. Consequently, UCD participants expressed no need to take responsibility in controlling overall healthcare costs. Underscoring this general position, participants overwhelmingly defined their costs of interest as "out-of-pocket" costs for a medical event, which resulted from copay or coinsurance. Hence, the only time the cost of the procedure may change patient behaviors is when patient out-of-pocket cost is impacted. When patients are not concerned about the cost of procedures until it hits their pocketbook, the potential of the Web tool to change behavior may be restricted. We make the prior statement with caution, because even in cases where out-of-pocket costs exist, UCD data does not reveal any clear indication that patients would use cost information from Web tool on a voluntary basis to change any care decisions.

Earlier in this chapter, we discussed recent trends that show a shift to a greater consumer burden regarding healthcare costs. Some participants in both the IDIs and focus groups showed some variance in their concerns about costs given the nature of the procedures and who were receiving the procedures (less concern with a child or loved-one). Based upon patients' existing values regarding healthcare cost responsibility and defining costs as their out-of-pocket expenses, could movement toward a greater consumer burden shift healthcare transaction processes toward "more of a shopping model?" Cosmetic surgery typically involves out-of-pocket costs and may provide a useful perspective in contemplating this question. Lee and Hoo (2006) argue that most physicians are compensated differently from the way the other professionals were. They further state that physicians would handle medical transactions differently, depending on how they were paid. For instance, a cosmetic surgery transaction has all the characteristics of a normal market transaction in which the seller has a financial interest in how all aspects of the transaction affect the buyer. The cost information of the typical cosmetic surgery is often readily available in three ways: (1) a package price in advance covering all services and facilities; (2) price comparison/shop-around prior to the surgery; and (3) a price that is lower in real terms than the price charged a decade ago for comparable procedures despite considerable technological innovations in the interim. Advertisements may even indicate a price range. There is ample evidence to suggest that consumers consider costs and "shop around" and that cosmetic surgeons compete with at least some consideration to costs. In contrast, in more typical physician-patient interactions, physicians are not paid to be concerned about all aspects of the transaction and therefore typically ignore the effects on the patients of a variety of costs, including cost of time, the cost of drugs, and other additional costs. In summary, differences exist in decision-making for elective medical procedures (e.g., cosmetic surgeries), as opposed to necessary ones (e.g., life-saving surgeries). According to information retrieval studies (Taylor, Cool, Belkin, & Amadio, 2007; Xu & Chen, 2006), costs constitute a relevant factor in information seeking process of elective "less threatening" medical procedures, however, they may not be as relevant or important in selecting essential procedures.

CONCLUSION

Although trends are moving toward patient empowerment and considerations of healthcare quality and cost, patients are not currently empowered when it comes to healthcare quality and cost information. In addition, patients perceived that they had limited responsibility for healthcare costs. The ultimate reason to look at compatibility issues early in the design process is to have some foresight to determine and enhance the potential for technology acceptance and outcomes. In aggregating literature and insights from the UCD data, what healthcare transparency Web tools have to offer may become more compatible with the patients' decision-making process as the healthcare industry continues with emerging trends toward patient information empowerment and increasing patient healthcare cost burden.

Currently, providing health transparency through a Web-based tool will likely influence the consumer healthcare decision processes the most in situations not involving extremely serious healthcare conditions and when the consumer bears the greatest cost burden. Web-based tools that provide understandable comparative cost information and quality indicators may best enable healthcare patients in the decision processes. Furthermore, such tools may also best serve their purposes by providing features that help the consumer deliberate (e.g., forums with peers, calculator, and further contact information).

The Theoretical Compatibility Model (Karahanna et al., 2006) proved to be a viable framework for analyzing the patient perspective and may be well suited to further explore and test consumer health informatics issues related to quality and cost transparency (e.g., acceptance of such Web sites and actual changes of behaviors resulting from using the Web site), as well as other consumer health issues (e.g., adoption of various forms of patient health records). Future work will include assessing existing and forthcoming healthcare transparency Web tools' ability to raise cost and quality awareness and encouraging the use of this information as a change agent for decision-making.

APPENDIX A: FOCUS GROUP PROTOCOL OUTLINE

- To discover the current state of cost information –
  - Do patients have an awareness of costs – if so, sources?
  - How/if patients currently use cost information?
- To discuss the future state of cost transparency –
  - Relevancy of information – what do they need to know, when?
  - Information access – how do they want to get the information?
  - Credibility of information – what makes it trusted?
  - What other factors must play in with cost – i.e. quality?
  - At what point in time does the shopping process start? Proactive, Reactive, not Active?
  - Roles of decision makers/influencers – family members, friends, third party sources, physicians, etc.?
  - Which care situations are open to choice/cost considerations, and which ones aren't?
  - What features are most important when a procedure needs to be done? How does this vary by situation?
- To explore how to encourage use of cost information as a change agent -
  - Discussion about plan designs – current vs. prototypes – what would encourage cost research/factoring into decision-making?
  - Incentives to factor price into decision-making?
- To determine what patients mean by quality of care.

ABSTRACT

The User Experience (UX) is a crucial factor for designing and enhancing the user satisfaction when interacting with a computational tool or with a system. Thus, measuring the UX can be very effective when designing or updating a Web site. Currently, there are many Web sites that rely on collaborative tagging: such systems allow users to add labels (tags) for categorizing contents. In this chapter the authors present a set of techniques for detecting the user experience through Collaborative Tagging Systems and we present an example on how to apply the approach for a Web site evaluation. This chapter highlights the potential use of collaborative tagging systems for measuring users' satisfaction and discusses the future implications of this approach as compared to traditional evaluation tools, such as questionnaires, or interviews.

DOI: 10.4018/978-1-60566-208-4.ch009

INTRODUCTION

Collaborative tagging is the process by which users add metadata to a community-shared content, in order to organize documents for future navigation, inspection, filtering, or search. The content is organised by descriptive terms (tags), which are chosen informally and personally by the user. The freedom to choose unstructured tags is the main distinctive feature of collaborative tagging systems, as compared to traditional digital libraries or other systems of content organization, where the creation of metadata is the task of dedicated professionals (such as librarians) or derives from additional material supplied by the authors (Bennis et al. 1998, Csikszentmihalyi, 1997). Like all socially-generated structures, tagging is an adaptable process; it takes the form best supported by the content, letting users decide the categorization of such content, rather than imposing a rigid structure on it. Collaborative tagging is most useful in an environment like the World Wide Web, where a single "content classification authority" cannot exist and there is a large amount of data content being continually produced by the users.

The widespread success of collaborative tagging systems over the last few years has generated a large collection of data reflecting opinions on, and evaluation of, web contents. In this chapter, we look into the possibility of exploiting this large database to evaluate the user experience (UX) of web sites. UX is a multi-faceted construct recently introduced into the HCI agenda to describe the quality of an interactive system (Garrett 2003; McCarthy and Wright 2005). This construct is used to indicate how people feel about a product and their pleasure and satisfaction when using it (Hassenzahl and Tracktinsky, 2006). Responses such as aesthetic judgments, satisfaction or frustration, feelings of ownership and identity are the most prominent aspects of user experiences investigated in this new, comprehensive, HCI research area (De Angeli, Sutcliffe and Hartman, 2005; Hartman, Sutcliffe and De Angeli, 2007; Norman, 2004). Normally, these responses are collected in formal evaluation settings via questionnaires and/or interviews. Collaborative tagging may offer an interesting alternative, one which is cheaper and less prone to experimental bias. In this chapter, we present a technique to extract semantics from tagging systems, and interpret them to describe the user experience when interacting with on-line content.

This chapter has the following organisation. Paragraph 2 reviews related works on collaborative tagging systems. Paragraph 3 describes three different techniques that can be used to extract semantics from tagging systems. Paragraph 4 reports a method to derive semantics differential attributes from collaborative tagging systems, 3, and its evaluation. Paragraph 5 summarizes the chapter, delineates future trends in the use of collaborative tagging systems for automating evaluation techniques and draws the conclusions.

BACKGROUND

Collaborative Tagging Systems (Golder et al., 2006; Mathes, 2004) offer their users the possibility to index contents for organizing web-related information, sharing knowledge and opinions. There is a growing number of successful web sites which include collaborative tagging, allowing users to index and share different types of contents. Del.icio.us (http://del.icio.us/), for example, specializes on bookmarking, categorizing and sharing URLs, Flickr (http://www.flickr.com/) allows users to tag photographs they own; Technorati (http://technorati.com/) is devoted to tag weblogs; and Youtube (http://www.youtube.com/) allows tagging videos. Other interesting examples are Snipit (http://www.snipit.org/), which offers the functionality of bookmarking sections of web pages, and CiteULike (http://www.citeulike.org/) or Connotea (http://www.connotea.org/) that allow tagging and commenting references to academic publications.

Collaborative tagging systems allow users to become active contributors in the classification of web-content. Because of this characteristic some authors refer to them as "folksonomy" (Mathes, 2004), short for "folk taxonomy", albeit there is still some debate whether this term is accurate (Golder et el., 2006). Users of collaborative tagging systems do not only categorize information for themselves, but they can also share their classification and browse the information categorized by other users. In fact, many collaborative tagging systems have features for sharing contents and their associated tags among users. They also, offer functionalities for keeping contents private, shared only within a pre-set list of users, or public (shared with everyone).Therefore, tagging is both a personal and a social activity. According to the number of people who can tag the same content and/or to the level of privacy of the tag (shared vs. personal).Collaborative tagging systems are distinguished in "broad" and "narrow" systems (Van der Wal, 2005). A broad tagging system is the result of one item being categorized by many people (Del.icio.us is an example). This can generate a very diverse set of tagging, as different users can enter their preferred terms, with obvious semantic and syntactic variations. There will be some terms that are used by many people to describe one item or many items which are described by the same terms. The concentration of terms can take advantage of power laws (like the Zipf distribution (Zipf, 1949; Newman, 2005)) to quickly see the preferred terms for an item or items.). It states that the frequency of the occurrence of a term is inversely proportional to its frequency class. Zipf has discovered experimentally that the more frequently a word is used, the less meaning it carries.

A narrow folksonomy is the result of one person categorizing one item (Flickr is an example). In this case, tags are private, but users could decide to share their own photos allowing others to view their tags and thus their categorization of contents. When the contents (and tags) are shared with other users a narrow folkosomy can approximate a broad one; nevertheless since the option of sharing contents and tags is leaved to the final user we cannot strictly rely on it.

This paper concentrates on broad collaborative tagging systems, where several users index and share different content. We regard the folksonomy produced by these systems as a result of collective intelligence and social creativity (Fischer 2006): different users contribute to the establishment and dissemination of knowledge. In this vision, collaborative tagging systems are not only important for their primary task (e.g., information retrieval), but they assume a fundamental role in the quest for understanding the user experience. People tag content with words which have both denotative and connotative meaning; these tags are a reflection of their opinion on the content, the service provider and the interface design. We believe that tagging systems act as social dynamics enablers representing the real ”vox populi”; in fact, users can take advantage of tagging information shared by others(Nov, 2007). Tagging systems leave the users free to express their own opinion without restricting them in a frame, such as a questionnaire. We believe that this method is more likely to capture the ecological perception of the web site audience. Collaborative tagging systems offer a lot of unstructured metadata (tags) associated to many different contents (web sites, photos, videos, etc.) that can be used for measuring the UX of these contents over the Internet.

Moreover, collaborative tagging systems allow detecting variations over time, by analyzing how tagging evolve. The goal of our research is to develop a methodology to extract meanings from collaborative tagging systems and to use this information in order to understand what people think about on-line contents. This methodology requires a two phased process: (a) detecting semantics from tagging systems; (b) interpreting the meaning of this information.

DETECTING SEMANTICS FROM TAGGING SYSTEMS

Information retrieval (IR[1]) from unstructured contents such as those produced by tagging systems) is a complex task. A major problem relates to the fact that no current tagging systems have synonyms control (e.g. "Mac" and "Macintosh" do not coincide in Del.icio.us). For this reason, in order to use the information contained in a collaborative tagging system, we need to use techniques extracting semantics from users' tags. In the following paragraph, we discuss three information retrieval techniques that can be used to extract semantic features from tagging.

Many information systems use keywords or key phrases to search or browse collection of documents for specific terms and information. Not only are keywords used for searching relevant documents but also to index and categorize the content. Relevant information is indicated by the authors of a document and is placed in appropriate sections for emphasizing them. Typical examples are the title, abstract and author's name written with bold or in appropriate places of the document. This approach is useful if employed within document collection explicitly managing this information, such as newspapers articles. Nevertheless this information is not available in general and providing them manually can be tedious or inapplicable depending on the amount of relevant keywords or terms we want to provide for each document.

IR algorithms were devised to address this problem, trying to automatically extract relevant terms and keywords from unstructured document collection. IR algorithms employ two different phases (Turney, 2002): keywords assignment, and keywords extraction. Usually, there is a training phase where an initial default list of relevant keywords is provided to the system, thus using a controlled dictionary. The wider is the list, the greater should be the number of documents used to train the system by manually indicating the keywords included in each document (chosen among the given list). These types of algorithms are called training-intensive, i.e. a big training set is required to obtain good performance.; On the contrary, keywords extraction does not need any training since the keywords are directly extracted from the body of each document by using the information learned from the training phase and some similarity measure. In the next section, we present a selection of three IR algorithms that can be used to automatically extracting semantics from collaborative tagging systems.

PMI-IR

The PMI-IR (Point wise Mutual Information – Information Retrieval) algorithm employs the technology of a search engine, such as Google Page Rank, or Yahoo, (Krikos, et al. 2005; Kraft et al. 2006)) to extract the frequency of searched keywords within a collection of documents. In general, the algorithm takes as input a word and a set of alternative terms for that specific word. The output is the selection of the terms whose meaning is the closest to the given word. That is to say, the algorithm finds the synonyms by analyzing the co-occurrences of the terms with the given keyword and among them.

This is exactly the case for tagging systems, where we have a collection of contents labeled with different words representing keywords for that collection and we would like to group words having the same meaning.

There exist different ways of measuring the co-occurrence between two terms, but the one used by PMI-IR algorithm is based on the Point wise Mutual Information (1), where problem represents the given word (tag in a folksonomy), {$choice_1$,..., $choice_n$} represent the n alternatives for problem and P(problem, $choice_i$), i=1,..,n the probability of the co-occurrence.

$$\text{Score}(choice_i) = \log2 \left(P(\text{problem}, choice_i) / P(\text{problem})\, P(choice_i)\right) \quad (1)$$

If problem and $choice_i$ are statistically independent, then the probability of co-occurrence is described by P (problem) P ($choice_i$). If problem and $choice_i$ are not independent (i.e., they tend to co-occur) the numerator in (1) will be greater than the denominator and the ratio will describe the independence rank between the two terms.

By considering that P (problem) is assuming the same value for each associated $choice_i$ and that the log function is monotonically increasing, equation (1) can be simplified as follows:

Score (choicei) = log2 (P (problem, choicei) / P (choicei)). (2)

The conditional probability value P (problem| $choice_i$) is assigned as a measure of how close the words are (synonyms). This measure can be computed, for instance, by using a search engine like Google page rank or Altavista advanced search. P (problem| $choice_i$) represents the number of documents returned by the search engine, called hits, when searching for problem and $choice_i$. The term which is the most similar to the problem is the one that maximizes the measure as shown in (3).

To clarify how this algorithm can be used for extracting semantics from tags, let us give an example. In the first instance we consider as co-occurring two words appearing in the same document, for example tags used in del.icio.us for categorizing the same web site; e.g. www.microsoft.com tagged with both the words 'explorer' and 'windows'. In this context, the score assigned to each $choice_i$ is computed as follows:

Score (choicei) = (hits (problem AND choicei) / hits (choicei)). (3)

The equation reported in (3) assigns as score the value of the ratio between the number of documents containing the two terms (problem and $choice_{i)}$ and the number of documents containing only $choice_i$

The tag which is most correlated to the problem is the one obtaining the highest score value computed as of (3). This is a reasonable is a reasonable measure of similarity among tags and a given term, yet is has some problems. In fact, a good similarity measure should include the totality of the tags included in a tagging system and not only within a basic set of $choice_i$ terms. Different tags can have different meanings depending on the interpretation of the author of the tags. Thus, this approach is suitable for narrow folksonomies where clusters of tags are created by some users who upload the contents using their own way of categorizing contents which are likely to have a narrow and well defined range of synonyms.

Collaborative Tag Suggestion

A new IR algorithm (Xu et al., 2006) has been recently introduced, which is based on tag suggestions for annotating documents in collaborative tagging systems. This method assigns reputation weights to the authors of tags, on the basis of the accuracy of words entered. The system suggests terms to use as tags for documents based on the words which are most frequently used by users with good reputation (good sense-making).

This algorithm still keeps into account the magnitude of the co-occurrences of terms but using a subset of terms used by certain experienced users. The objective is to evaluate which tags are relevant (keywords) for the documents in the folksonomy. This objective is achieved by a ranking among users indicating which ones participate positively (the most reliable) on the tagging process. The notation used for this algorithm is defined as follows:

- Ps (ti/tj; o): it is the probability that a user labels an object *o* with the tag *ti* knowing that the tag *tj* has already been used for the same object (i.e., document). To measure the correlation between the two tags on the object o, the algorithm considers the ratio between the number of users using both ti and tj, and the number of users using only tj.
- Pa (ti/tj): it is the probability that any object is labeled with the tag ti knowing that the tag tj has already been used for the same object. In this case the observation refers only to the tags and not to the objects. To

measure this correlation between the two tags, the algorithm considers the ratio between the number of users using both ti and tj, and the number of users using only tj.

- S (t, o): indicates the score of the tag t on the object o, computed by summing the number of users that labeled o with t.
- C (t): indicates the coverage of a tag, which is the number of objects labeled with t. The greater is the number of objects tagged with t, the less specific is the meaning of the tag t. In other words if t is used very often it is a generic term.

The algorithm works by iterating the selection of the tags ti for which S (t, o) is high and multiplying this by the inverse of C (ti). After selecting the ti with the maximum score, the scores of every other tag t' are changed according to the following statements:

- t' score S (t',o), is decreased removing redundant information, i.e. subtracting the value of the probabilities product of t' and ti used together. In this way the superposition of the suggested tags is reduced, as in S(t',o)= S(t',o)- Pa(t'/tj) S(/tj,o)
- t' score S(t',o), is increased if it co-occurs with the selected tag tj over the object o, as in S(t',o)= S(t',o)+ Ps(t'/tj;o) S(/tj,o). This procedure allows dealing with basic level variations of tags, normalising the score for tags like BLOG, BLOGGING, and BLOGS.

The drawbacks of this approach are related to the fact that there exist narrow folksonomies, like Flickr, where every object o (i.e. a document) is own by the user that uploaded it, or by users to whom the owner has granted access permissions. In these cases, we do not have access to all the information needed for running the algorithm over a wide number of tags. Thus the clustering process does not necessarily represent the users' opinion on the tagged topic; but a specific feeling about the shared content (e.g. a link to a web site, and thus the web site itself) can be detected by means of finding related words among a community of users sharing the same interests.

The Semantic Halo Algorithm

In our previous work we introduced a Semantic Halo technique in order to deal with word semantics in tagging systems (Dix et al., 2006). The basic idea consisted of using co-occurrences of tags to cluster their relationships and meanings.

The Semantic Halo is defined as a set of search results for a given tag made by a set of four features, labeled as **4A**:

- **Aggregation**. Representing all the tags linked or related to a given tag.
- **Abstraction**. It is similar to aggregation but it relates to a direction (increasing and decreasing), thus it contains two subsets:
  - Generalization, tags increasing abstraction with respect to the given tag,
  - Specialization, tags decreasing abstraction with respect to the given tag.
- **Ambience**. It is the context for a given tag. It includes all the possible tags appearing in the same context, and that will be useful for augmenting or refining the user query. This set is built from a basic context set.
- **Age**. It is a list of the Ambience feature elements over time. It helps in retrieving tags ordered by meanings given to them over time.

The algorithm was tested within the Del.icio.us community. In this environment, users submit their links to a website, adding some descriptive text and keywords, and Del.icio.us aggregates their posts with everyone else's submissions allowing users to share their contributions. The algorithm was implemented using Del.icio.us programming APIs (Application Programming Interfaces). This procedures allowed to collect results while the users where tagging. Because the Del.icio.us community is very large and active this test resulted in a quite complex but effective test.

For example, given the tag "university", which is quite general, our algorithm searched over Delicious for related tags and retrieved:

Ambience = {'open', {'learning', 'University'}}
Abstraction = {'online', 'education'} U {'colleges', 'high', 'degree', 'distance', 'Commons'}
Age = (('learning', 'University'), ('open'))[2]
Aggregation = {'soccer', 'gradschool', 'corps', 'indoor', 'course', 'masters', 'research institute', 'cites', 'cincinatti', 'peace', 'demographic', 'content', 'courses', 'innovators', 'urban', 'tournament', 'entrepreneurship', 'liverpool', 'york', 'community-college', 'schools', 'Illinois', 'abroad', 'Content', 'latino', 'Course', 'complexity', 'planning', 'Initiative', 'academiclibrary', 'enterprise', 'semantic-web', 'Education', 'grad', 'scholarship', 'teaching', 'college', 'school'}.

We can observe that the Ambience set is composed of two subsets, associated with two different contexts or meanings of the 'university' tag. The algorithm can solve also basic level variations[3] since the tag 'University' with the capital 'U' is strongly associated with the 'university' tag (without using any parser). The first part of the Abstraction set is related to generalization of the given tag, while the second part is specialization, thus providing a partition of the related tags in increasing and decreasing abstraction. The Age sequence is the ordered set of contexts (meanings) with respect to last updates. The Aggregation set lists all the related tags, and even if there are unwanted tags the majority (as shown in the example above) is clearly related.

The Semantic Halo algorithm is applicable in general to broad and narrow collaborative tagging systems but has the drawback of employing a clustering technique that can be less effective or precise in specific sub-domains originated by users' tags.

Summary

All the different algorithms presented in these paragraphs can be employed for extracting semantics from tags by automatically organising them in classes or synonyms. The designer can choose different algorithms or techniques depending on the characteristics of the considered tagging system.

PMI-IR is quite fast to compute and since it is a standard approach within the IR field, many implementations can be found. The drawbacks of this approach are related to the fact that tags have different meanings depending on the sense-making of the users. As a consequence, for retrieving useful semantics the algorithm should span over the entire collection of tagged contents (considering the different choice_i words). The Collaborative Tag Suggestion approach is very effective but it should be avoided when dealing with narrow tagging systems (Flickr for example) when every tagged content is owned by the user or shared with a specific subset of users granting permissions to them. Finally, the Semantic Halo can be used to extract semantics both from broad and narrow Collaborative Tagging Systems but it is less precise in specific sub-domains of tags (users' annotating contents in on specific domain or topic).

Choosing an IR algorithm is a first step for organizing unstructured content, which is a prerequisite for evaluating the UX over contents shared by tagging systems.

SEMANTIC DIFFERENTIAL IN COLLABORATIVE TAGGING SYSTEMS

This section describes a method to evaluate the information extracted from the tags in order to obtain a measure of the user-experience with web-sites. The evaluation phase in our approach is based on the elaboration of the concept of semantic differential introduced by the psychologist and communication scholar E. Osgood (1975). The original work of Osgood focused on the measurement of meaning, addressing issues of word semantics and psychological differences between words. In his influential research the author proposed a method (the semantic differential) to highlight individual differences in the attribution of meaning to words. The semantic differential measures people's reaction to stimulus words and concepts. Participants are invited to rate the stimulus with a bipolar scale. Each extreme of the scale is labeled by contrasting adjectives, such as bad-good. This technique has been frequently used in psychometrics to measure a number of psychological constructs, and more recently has been employed in HCI to build user satisfaction questionnaires. An example of opposite couples of adjectives used by Osgood methodology is shown in Table 1.

Osgood research has demonstrated that ratings on bipolar adjective scales tend to be correlated, and to cluster around three basic dimensions of response, which account for most of the covariation in ratings. These dimensions, labeled as Evaluation, Potency, and Activity (EPA), have been verified by factor analyses and replicated in an impressive variety of studies.

In our approach, there are no fixed couples of opposite adjectives but the information is extracted from the adjectives freely introduced by the user. The adjectives are then associated to one of the three dimensions evaluation, potency, and activity

Table 1. Opposite couples of adjectives used by Osgood

1.	Angular/Rounded,
2.	Weak/Strong,
3.	Rough/Smooth,
4.	Active/Passive,
5.	Small/Large,
6.	Cold/Hot,
7.	Good/Bad,
8.	Tense/Relaxed,
9.	Wet/Dry,
10.	Fresh/Stale.

Evaluation

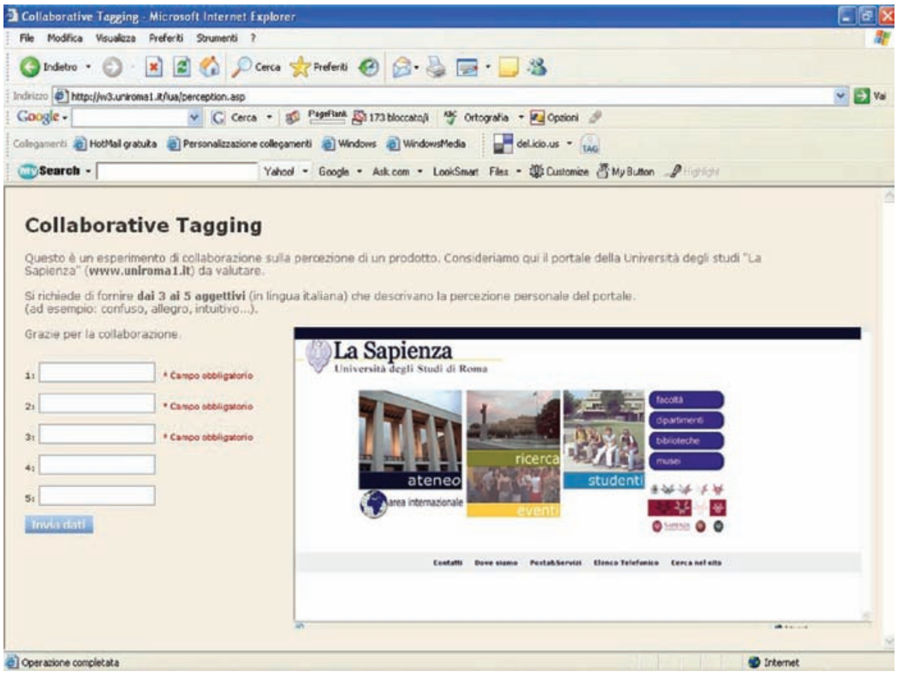
In order to test our methodology of semantic differential through collaborative tagging systems we built a basic collaborative tagging system. Users could add tags for categorizing contents, we explicitly asked users to use adjective as tags for categorizing the contents. Then by employing an IR algorithm we obtained a structured representation of the tags. Successively, we clustered structured tags into groups of adjectives. These groups of adjectives where used for applying the semantic differential technique and obtaining a measure of the UX on the web-site contents.

The objective of our evaluation study was to evaluate the experience of a community of users with respect to the Sapienza University of Rome Italian web portal (www.uniroma1.it). We choose this target because many users of the web portal were complaining about its features and usability. In fact, the Sapienza web portal has now been redesigned.

The community considered in this experiment is composed of 48 people. The majority of users (60%) were students. The remaining sample was split in 20% of administrative staff and 20% of academic staff.

Participants were invited to browse the web-site and tag it with their preferred set of adjectives. This

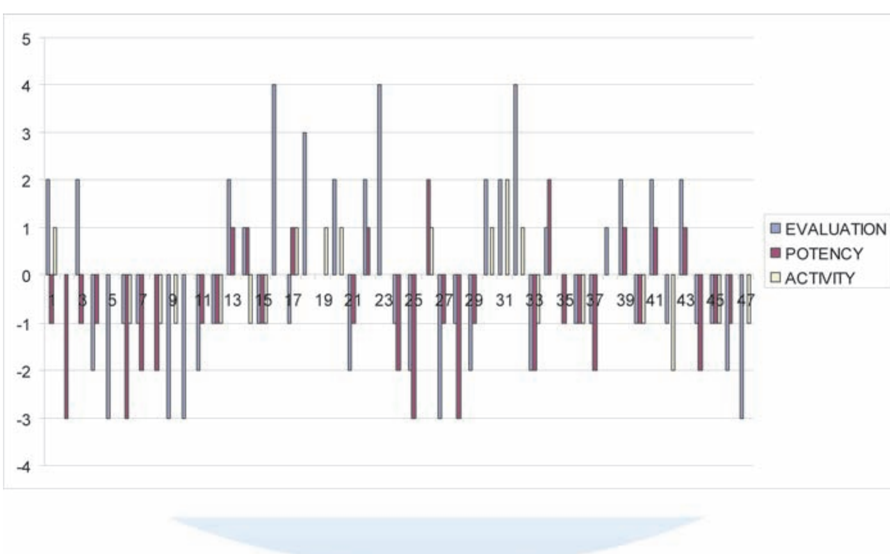
Figure 1. The custom collaborative tagging system including tagging labels and interested web site



system provided users with classic collaborative tagging functionalities, such as: presenting the document to be tagged and the text labels where the corresponding tags could be added. Figure 2 shows the tagging systems used for the experiment, even if displayed in Italian the tagging and web site area are clearly visible.

We collected around 162 tags from 48 individuals in a 2 weeks time-frame. As a first step we analyzed the frequency of each tag (adjective) as

Figure 2. A bar-chart view of the users with respect to the selected classes (evaluation, potency and activity)



presented in Table 2. Analysing the adjectives, it appears that there is a sort of binary distribution of the general tags among positive and negative evaluation. Looking at the frequency distribution (for example f= 11), we found that two very different tags (simple and dazed) are the most frequently used. This effect is evident for almost every couple of tags in Table 2. The effect was also evident in the complete dataset, even with less frequent tags. This let us hypothesize that even after the clustering process (assigning tags to the three classes: evaluation, potency and activity) the user perception would be split in two neat categories according to the overall binary perception: positive or negative.

We categorized the tags in the three classes according to the clustering proposed by Osgood in (Osgood et al, 1975), as shown in Table 3. We used the PMI-IR to automatically measure the distance between the selected adjective (Problem) and the couples of adjectives contained in the Osgood scale. This approach has been employed for the positive and the negative meanings of a tag. The three major factors for a tag to belong to a class are:

- **Evaluation:** Representing the overall feelings about the web site (adjectives like good or bad);
- **Potency:** Representing the expressive power and impact on the perception of the web site (adjectives like strong or weak);
- **Activity:** Representing the possibilities and functionalities (at informational level) offered by the web site (adjectives like: active or passive).

Table 2. Table showing the most occurring tags

Tag	Occurrence
Simple	11
Dazed	11
Clear	6
Sad	6
Comprehensive	6
Inconsistent	5
Intuitive	4
Useless	4
Poor	4

By using the clustering results we analyzed the experience of each user, expressed by the tags inserted in the system with respect to the selected classes (evaluation, potency and activity) and their positive or negative meaning. Figure 2 shows individual results for each user (1-47[4]).

Figure 3 suggests that, in general, the user evaluation of the web-site has been quite negative as most of the scores fell in the negative half of the scale. Potency is the weakest dimension. Furthermore this graph highlights that users with a positive evaluation of the web site focus their attention to that particular class (the Evaluation class), which deals mainly with strong feelings about a web site (adjectives like: good or bad, nice or ugly, etc.).

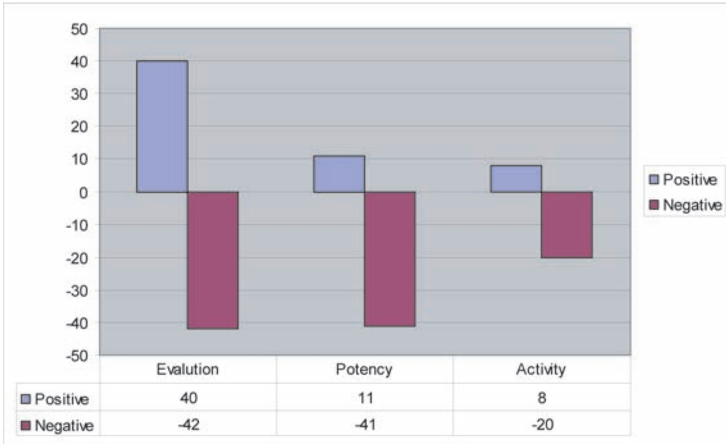
CONCLUSION

This chapter presented a UX evaluation approach consisting of three steps:: 1) select a collaborative tagging system containing the content for which we would like to evaluate the users' experience

Table 3. Classes assigned after the clustering phases and number of tags falling in their relative class; the third rows represent the number of tags per class with positive and negative meanings, (+n) stands for n tags in that category with positive meaning and (-n) for the negatives.

Evaluation	Potency	Activity
82 (+40) (-42)	52 (+11)(-41)	28 (+8) (-20)

Figure 3. A bar-chart view of the overall evaluation, potency and activity



(Del.icio.us for web sites, Flickr and YouTube for multimedia content, Technorati for blogs); 2) employ an IR technique to extract semantics for users' tags and group them together by cluster of synonyms or related tags; 3) use the data automatically extracted from the clusters of tags to detect the overall impression of users (UX) over the selected content (web sites, multimedia systems, blogs, etc.) by grouping tags according to the semantic differential technique. We reported an example of how this evaluation approach can be applied on an ad-hoc collaborative tagging system. Anyway, this procedure can be applied to a wide range of collaborative tagging systems. In our test we asked users to add adjective tags to keep it controlled but generally we will have plenty of available tags already inserted by users of collaborative tagging systems. What do you mean by that? You need to explain further by rewriting this sentence.

Our approach suggests the importance of collaborative tagging systems in the evaluation of the end users experience. It seems to be a promising and cost effective alternative to questionnaires or interviews.

Collaborative tagging systems are becoming increasingly popular on the Internet. There are many reasons why users are motivated in volunteering their time to support these on-line communities (Clary et al., 1998), adding information to collaborative tagging systems over the web; nevertheless such systems keep growing as a social phenomena. We can take advantage of this huge number of users to detect the user experience perceived by them when adding tags for categorizing a content of interest over the web.

KEY TERMS

Collaborative Tagging Systems: Collaborative tagging (also know as folksonomy, social classification, social indexing and other names) is the practice and method of collaboratively creating and managing tags to annotate and categorize content[5].

Distributed Intelligence: In many traditional approaches, human cognition has been seen as existing solely "inside" a person's head, and studies on cognition have often disregarded the physical and social surroundings in which cognition takes place. Distributed intelligence provides an effective theoretical framework for understanding what humans can achieve and how artifacts, tools, and socio-technical environments can be designed and evaluated to empower human beings and to change tasks[6].

Information Retrieval: Information retrieval (IR) is the science of searching for information in documents, searching for documents themselves, searching for metadata which describe documents, or searching within databases, whether relational stand-alone databases or hypertextually-networked databases such as the World Wide Web[7].

Semantic Clustering: Identifying and disambiguating between the senses of a semantically ambiguous word, without being given any prior information about these senses[8].

Semantics Differential: A type of a rating scale designed to measure the connotative meaning of objects, events, and concepts[9].

Usability Evaluation: Usability usually refers to the elegance and clarity with which the interaction with a computer program or a web site is designed[10].

User Experience: User experience, often abbreviated UX, is a term used to describe the overall experience and satisfaction a user has when using a product or system[11].

ENDNOTES

1 Searching a body of information for objects that match a search query, particularly a text or other unstructured forms (http://www.cs.cornell.edu/wya/DigLib/MS1999/glossary.html).

2 Round parenthesis are used in the mathematical sense that we are not enumerating a set here but we consider an ordered sequence in the case of Age feature.

3 Basic level variations are consider to occur when, having two words differing by the case or including or not a dash.

4 One user has been deleted from the sample because inserted tags as spam, due to the anonymous login to the system.

ABSTRACT

Adaptive Hypermedia is an effective approach to automatic personalization that overcomes the difficulties and deficiencies of traditional Web systems in delivering the appropriate content to users. One important issue regarding Adaptive Hypermedia systems is the construction and maintenance of the user profile. Another important concern is the use of Semantic Web resources to describe Web applications and to implement adaptation mechanisms. Web Usage Mining, in this context, allows the generation of Websites access patterns. This chapter describes the possibilities of integration of these usage patterns with semantic knowledge obtained from domain ontologies. Thus, it is possible to identify users' stereotypes for dynamic Web pages customization. This integration of semantic knowledge can provide personalization systems with better adaptation strategies.

DOI: 10.4018/978-1-59904-974-8.ch014

INTRODUCTION

With the enormous quantity of documents that are now available on the Web, accessing and collecting the desired and relevant data has become a difficult task that produces low quality results. The Websites adaptation allows the minimization of this problem as an adaptive application generates Website content or the structure in accordance with a class of users. In fact, the personalization aspects are a critical factor for the successful user experience. As a personalization example, it is common now to find several customization options in an increasing number of Websites. The reasons for this are due to the diversity of users and its experience, intents, needs, preferences and even available equipment and software. The design of a Website with thousands of daily visitors will face hard time to fulfill these very different expectations. The personalization resources available can help users to have a more personal interaction, by observing their needs and preferences.

There are many different definitions for "Web personalization" in the literature. In a more general sense, it is considered as a set of actions that fine-tune the results of some user interaction, regarding this user or a set of similar users (Mobasher, 2005). The practical personalization depends on the context. For an e-Commerce Website it may be related to the set of products that are shown to the user each time he logs on, but for other applications it may refer to the interface organization, the navigational structure and content options. All approaches have their specific problems and some of them are hybrid, combining their better techniques (Middleton, 2004; Kleinberg 2004). It is important to notice that a superior result for the personalization requires not only an efficient approach to the analysis of the contents or users behaviors, but it is also dependent on the Website life cycle. The personalization application should be integrated with tasks such as content management, users profile management, adaptation strategies and interface generation. These tasks are well known in Adaptive Hypermedia initiatives.

Adaptive Hypermedia (Brusilovsky, 2004, 2001; De Bra, 1999) has as its objective the establishment of better user experiences by adapting hyper-documents and hypermedia to the users' needs, preferences and goals. Usability improvement is achieved with the construction of models that represent the users' objectives, preferences, previous knowledge, and skills. The use of these models, together with some complementary information as context, usage records or adaptation rules, allows the identification of possible topics of interest, restrictions and personalization options. In addition, domain information is very important in this process and drives the adaptation choices. This can be with respect to different aspects of a Website, such as its content or structure. Briefly put, this adaptation is based on the relationship between information concerning the application domain and information regarding the user profile.

One important topic in Adaptive Hypermedia systems research is the generation and maintenance of the users' profiles. Some approaches create the user profile from data obtained at the registration process, others incorporate the results of interviews and some perform automatic acquisition of information tracking the resources usage. In general, the profile based on the user identification tends to generate information valid over long periods. In some circumstances, short-term information can also be very useful and this kind of profile relies almost exclusively on the user interaction.

Web Usage Mining originates in prior Data Mining research with the purpose of automatic or semi-automatic discovery of Websites users' access patterns to generate information to be used by recommendation systems or by personalization systems (Mobasher, 2005). Analyzing the approaches to the generation of users' profiles by Web Usage Mining, a general pattern is identified and involves several stages (Markelou, 2005; Woon, 2005) that are briefly cited. The first is the acquisition of usage data. The second stage is dedicated to the pre-processing of data and the identification of access sessions amongst other necessary adjustments due to the Web environment (proxy servers, cookies or access errors, for example). At the end of the second stage, data is organized in appropriate formats for patterns mining where association rules and clusters can be generated or frequent pathways indicated. The third and last stage deals with the analysis and handling of these patterns in specific applications or contexts.

From the analysis of the obtained patterns, clusters identified or validated association rules, it is possible to generate complementary information to support the adaptation stage of Adaptive

Hypermedia systems. Nevertheless, it should be clarified that the patterns are obtained mainly with the access information present in the data for each user session. As mentioned, Web Usage Mining makes possible the capture and analysis of the behavior characteristics of Website users allowing the use of mechanisms directed toward personalization and adaptation (Aldenderfer, 1984; Brusilovsky, 2004). Despite being appropriate, this approach can be extended and improved by the use of semantic information associated with content access and navigation information.

An Adaptive Hypermedia application can discover better personalization choices by relating the semantic knowledge of a domain application, such as structural relations, with the usage information, such as navigation patterns. Some complex objects and some specific relation will not be treated with content-based or user-based techniques, as they have no representation in these systems. The representation of such complex objects and relations is possible with a domain ontology, which provides constructs for concepts and its relations definition. In a Website case, ontology provides the content concepts description, the hierarchies between them and the representation of some other existing relations. Domain ontology can be constructed by experts, manually. It can also be accomplished by using Machine Learning, Web Mining and Natural Language Processing techniques. The nature of the application can suggest the more suitable technique or combination.

The use of semantic knowledge, along with usage information, can lead to better knowledge discovery, by treating relations not applied in the other techniques. In general, this improvement takes two forms, which are the use of the semantic information in the pre-processing stage, enriching the pattern generation, or the use of the semantic information in the last stage, in combination with the adaptation itself (De Bra, 2004).

This chapter describes some possibilities for the acquisition of user profiles based on Web Usage Mining and domain ontologies. The main objective is to present the integration of semantic information obtained through the Website domain ontology with usage information obtained from the data gathered from user sessions. In addition, there is the intention to bring information to discuss if it is possible to identify more precisely the interests and needs of a typical user with these resources. The following sections provide some important background information on the Web personalization and Web Mining, ontology construction and semantic integration possibilities. The requirements for the semantic knowledge and usage information integration are discussed and finally some aspects of an Adaptive Hypermedia application based on the concepts of semantic application modeling are presented.

BACKGROUND

This section describes some concepts related to the main topic of this chapter. It provides the necessary background to the analysis of related works presented in the next section and to understand the integration approach described.

Web Personalization

The definition of Web personalization is found in the literature with some variations. In a general form, it is considered as a set of actions that adjust the results of user interaction, regarding this user or a set of users (Mobasher, 2000). In some cases, like an online bookstore, it corresponds to products indications. The scope for this kind of personalization can be very broad, ranging from items such as books or music to stocks, computers or cars. Another personalization example is the flexible organization of the user interface or the selection of contents. For example, the layout elements can be presented with more textual information, with differences in graphic elements, the options displayed in menus or the hyperlinks may be organized in more adequate manner for some user and the content may be more concise or have more details.

The approaches for the personalization can be grouped in content-based, collaborative-filtering or in some hybrid forms with both characteristics. Its differences rely on the strategies and information used to the personalization options generation.

In the content-based approach, the users' personal profiles represent mainly their interests. The Websites content is classified with respect to some subjects. Some metrics to evaluate the subject proximity to the users' interests are then applied for the generation of personalization. This approach can be found in several works, with small variations, but the principal aspect is the adaptation of a Website based on the preferences of the user (Lieberman, 1995; Mladenic, 1999; Mikroyannidis, 2004). Some advantages are found in this approach in situations as Web Information Retrieval, allowing the filtering of a large amount of pages based on the user profile. For example, a Website about movies can personalize the user navigation based on the previous shown interests and the options in the movies database. While this advantage can be relevant, it may also characterize some ineffective situations, when the user has a new interest, in an area not yet described in the profile. Another problem is that some useful semantic relations cannot be applied, as in cases of a more specific or more general approach for the same topic or in cases of different objects used in the same process and thus related.

The collaborative filtering techniques do not perform analysis in the content, but instead they focus on the preferences or activities associated with a specific user. These are then compared with all the other users and can lead to the identification of a set of users with common interests and preferences. There are several options to identify these relations, as the access to similar Web pages, the purchase of related items, the choice of similar options, the selection of similar feedback in ratings options and so on. Once the set of users with similar interests is defined, the personalization can be carried out by observing items not purchased or pages not accessed by a specific user, for instance. As the set of users is found to have the same preferences, it is assumed that one individual in this set can be interested in the same operations performed by the others. This technique, also known as user-based, can present problems in some situations, as in the publication of a new page or the release of a new product. Since the users do not have the necessary time to access, the item cannot be associated with some personalization action (Konstan, 1997; Balabanovic, 1997; Sugiyama 2004).

Some approaches using both techniques are known (Middleton, 2001; Kleinberg, 2004) and can be found as a way of reducing the limitations of each one. With both content and user preferences information the personalization system can be adapted to perform its tasks in a more efficient way.

Web Mining

Web Mining is defined as the discovery and analysis of useful information on the Web, with the objective of identifying behavior, characteristics, trends and navigation patterns (Cook, 2000; Kosala, 2000). There are three main areas of interest in Web Mining, described as Web Content Mining, Web Structure Mining and Web Usage Mining (Zaiane, 2000; Mobasher, 2005). Each of these is associated with some specific data collection originated in the records of Web Server activity, in the Website structure or in its content.

Web Content Mining is the process of extracting useful information from the content of Web documents. The Web content can be unstructured (plain text documents), structured (when dynamic pages exhibits content from databases) or semi-structured (HTML documents). The results can help information retrieval operations and personalization systems (Popov, 2003; LeGrand, 2002; Alani, 2003; Loh, 2000). The main advantage of this approach is the possibility to discover and classify documents and Web pages with respect to their content.

The Web Structure mining is the process of knowledge discovery driven by the Websites links structure. The topology of a site, its organization and the link structure are used to identify patterns. Some useful information extracted from these patterns can be, for instance, the identification of pages that represents collection of specific information, or collections of general information, with a large number of references, like in the concept of hubs and authorities. There are some examples of algorithms such as HITS (Kleinberg, 1999) and PageRank (Brin, 1998), that are based on this kind of data.

The objective of Web Usage Mining is to identify browsing patterns. This is achieved by analyzing the navigational behavior of a group of users. The information necessary to do this is available mainly in Web server log files. Web Usage Mining is carried out in well-defined stages, already mentioned in the text. These are the acquisition of usage data, pre-processing, analysis and usage. In the following sections, these stages are briefly described and discussed.

The first phase involved in the process of Web Usage Mining is concerned with the usage data processing. The processed data is extracted from the Web Server access log files or is generated from a script code included in the Web pages. One of the advantages of both forms of data collection is that they allow a Data Mining approach to the generation of user models for a specific Website, given the ability to obtain the data that is automatically generated when the pages of a Web site are accessed.

These access log files, created by Web Server software, were originally meant to aid debugging and to perform some simple statistics operations (Kohavi, 2001). The Common Log Format (Nielsen, 1995) is widely used, despite the existence of some improvements in other similar formats, like in the Extended Common Log Format and in other proprietary options. The Common Log Format is structured in text documents where each line represents a request or part of one. The main fields are the remote host identification, the remote user identification and login name, the date and time of the request, the exact request line received from the client, a code which indicates whether or not the file was successfully retrieved and the number of bytes actually transferred. The Extended Common Log Format adds two fields, the referrer and the user agent. The first indicates the URL accessed by the client browser before the request. The second indicates the browser software used in the request. In these formats, when some information is not available, it is replaced in the log with a minus sign ('-'). A few lines of a typical log file are shown in Figure 1.

Some problems can be observed. The verbose structure of these log files tend to be very expensive to process, because each single transaction made by the Web Server is stored in the file. Some of these are not relevant for the mining activity, for example, the retrieval of an individual image file, CSS (Cascading Style Sheet) or a script file. There is also a difficulty in the user identification, which requires some extra processing. Since the

```

user identification and its sessions are important information, the mining systems need to use some heuristics. The date and time, along with the remote host identification are applied to separate the session log information.

To overcome some limitations observed in the log files processing, there is another approach that uses some specific script code, embedded in the pages displayed to the users. This process allows the recording of the real actions performed, without cache or proxy problems, and in real time, while the log file approach involves an offline processing step (Peterson, 2005). The preprocessing phase is simplified with these systems, because the transaction data is already stored in an appropriate form. However, this is achieved with some additional costs in each page view. These costs are due to the scripts embedded in the pages. Some are executed when the page is generated, while others are executed at the page restitution by the Web browser, by client-side script languages such as JavaScript (Netscape, 1998).

The tasks involved in this first preprocessing phase starts with data cleaning, when the log file is examined and some irrelevant entries are removed. Examples are the entries related to software robots doing crawling activities, or related to the structure of the pages as in the case of frames utilization. The next task is the user and session identification. Since the log files can be employed without user identification, there exists the necessity of processing the records to identify users, in general with information such as IP (Internet Protocol) numbers, date and time of the access. When some user, an individual accessing the site not a specific person, is identified, there is also the necessity of session identification, because it can be of importance for some mining process to identify different sessions of a user. There are also peculiar situations to deal with, as in the case of the use of cache mechanisms in the client software (the Web navigator), in the occurrence of errors or in the case of missing stored information in cookies.

After the processing and adjustments in the original data available, different techniques are applied in the knowledge discovery, such as sequential pattern mining, association rule mining, clustering and classification. The most frequent are the association rule and the sequential pattern mining. The first relates items and are used to identify groups of pages visited in similar ways by users. The second allows the most employed sequences of pages to be found. The other techniques are applied to group users into similar interest sets and to identify users in predefined interests groups.

Each technique mentioned can present results that are adequate to different tasks in the final phase, the adaptation or personalization. More details are described in the following sections.

Semantic Web

The Semantic Web initiative has the objective of solving some deficiencies observed in the traditional Web and implementing some improvements to the present possibilities of automated Web content processing. The first task in this direction is the description of documents in a more structured manner, allowing software agents to automatically manipulate such documents. In less structured languages, such as HTML, it is not possible to automatically perform tasks that depend on the documents content. As stated by Berners-Lee et al. (2001), these structured documents along with domain ontologies and inferences mechanisms can overcome the actual weakness of the Web. Documents in the Web are easily accessed by humans, but are not available to some automatic use.

One of the main requirements is the use of URI (Universal Resource Identifier). Another is the use of Unicode (Unicode Consortium, 2006) for codification, in order to ensure platform interoperability. The proper separation between structure and content in the documents is achieved with the use of XML language (Freitas, 2003). If some metadata pattern, such as RDF (Resource

Description Framework) (Herman, 2007), is utilized, it is also possible to describe information about the document. This can be very useful and helps to annotate the semantics of documents with information that can be automatically processed enabling a large number of new applications. When this metadata are described in accordance with some user's community standard, they provide the means for a consistent terminology to be at the disposal of several applications. As an example, the "Dublin Core Metadata Initiative" (Dublin Core, 2007) can be cited. It was originated from an open organization engaged in the development of metadata standards that created the "Dublin Core Metadata Element Set" which is widely known and used in resources descriptions. In this metadata set, elements as "creator", "contributor", "coverage", "date", "subject" and others are described with a precise meaning. Its adoption by communities allows precise information exchange, by documents with metadata annotation.

For some operations, the minimal metadata annotation can be insufficient. Descriptions that are more effective can be done with ontologies, in which a set of concepts and relations belonging to a particular domain may be shared. In this case it is possible to achieve more effective treatment of the documents information, with diverse objectives, as Information Retrieval, Electronic Commerce, Distance Learning or Data Integration, to name a few possibilities (Hendler, 2002; Nilsson, 2003). There exist some specific languages for the ontology description, as the OWL (Ontology Web Language) (Herman, 2006) which have the objective of precise concepts and relations description. According to Heflin (2004), this language supports the ontology description and integration, along with inference and query operations. The ontology creation can be done manually, by an expert in the specific domain, or automatically, using some Machine Learning techniques (Fensel, 2001; Fensel, 2002). Some principles, already indicated by Grubber (1993), must be adopted, including coherence, clear description of terms or facilities for ontology extension. The ontology editor usually verifies some other principles, as its correction.

The possibilities for ontology application depend on the knowledge acquisition operation, which can be a difficult task. Some Websites have a large number of pages and the manual creation of an ontology that describes the Website can be unfeasible. For this situation, it is useful to apply automatic creation mechanisms.

Adaptive Hypermedia

Several Adaptive Hypermedia systems were developed by different research groups and address different application areas. The best known are those for education, information retrieval and tourism, library and museum support. Some systems have identification options that connect the users with the profile information. Others are driven by non-invasive techniques and try to get the information for the profile generation in an automatic way (Dolog, 2004). The large volume, the diversity in formats and the great rate of information generation and update makes it hard to treat manually in an adequate form to the different users. In addition, the great number of users and diversity in interests and preferences makes it difficult to generate an efficient and usable interface in a system without adaptive options (De Bra, 2004).

The research in the Adaptive Hypermedia field has the objective of improving the users' satisfaction while using these systems. This usability improvement is achieved by the construction of models that can represent the knowledge, skills, objectives and preferences of the users. Besides the user modeling, some specific techniques are observed in the interface construction and in the usage recording. Some complementary information, as the application context, usage data, adaptation rules, allows for the identification of possible topics of interest and useful adaptations (Brusilovsky, 1996; De Bra, 1999).

To make possible the adaptation, the documents should be related to the domain model and its concepts. These can be more general (broad concepts), can represent groups with topics about a general subject or can describe specific information about some topic. The possible relations will be at the system disposal and the contents can be related to the domain model (Wu, 2002).

The system's generic operation can use these descriptions, in different tasks. The first one is the recording of the users' behavior. In Internet systems, this behavior can be associated with sequences of page accesses, for instance. A second task is to apply some processing method over the user model to classify the content information, regarding its profile. The third one is to combine this information to generate the interface, according to the identified possibilities.

The user profile can be composed of information that is valid over long or short time periods. Normally data with a long period of validity requires the identification of the user to be correctly acquired. In the context of educational systems, it is desirable and even necessary that the system user be identified to allow the update of the profile of the accessed information. In other circumstances, however, this identification could be undesirable for the users, and even be unnecessary given that it is also possible to obtain good results when the adaptation of a Web site is based on a class of users, represented by stereotypes, rather than on specific users. The user profile can be generated based on knowledge or behavior. The knowledge-based approach, that tends to make use of static models, can apply tools as interviews, tests and questionnaires. The behavior-based approach employs data from the users' interaction. These data can be from different periods and are applied in order to extract useful patterns (Middleton, 2004; Kobsa, 1993).

The adaptation in Adaptive Hypermedia systems refers to the contents and its presentation form - information is presented with different details. In addition, the information can be shown in an interface with more text or more images, some specific color configuration or with auxiliary media, as sound, video or animations (Christopher, 2002). Also the new devices' capabilities requires that some specific information initially applied to only one context will be sent now to a diversity of devices, with varied capabilities in memory, display and processing power (Petrelli, 2005). The possibilities of integrating sensors as input to these systems also can be very useful because of the effective interest delimitation that it allows the generation and short cycle of recording, and the inference and adapting process (Zimmerman, 2005).

RELATED WORKS

The Web Mining process can be related to the discovery of knowledge in sources such as the content, the usage records or the structure of Websites. This knowledge can be analyzed and, if considered useful, applied in adaptation or personalization tasks. Some details about the information obtained with these sources can be helpful to identify limitations observed in traditional systems using Web Mining. These limitations are described and related to possible solutions, with the use of some complementary semantic knowledge.

When the content of the pages is treated like a bag of words, it is difficult to the mining process to identify a relation between different pages dealing with the same concept but described with synonyms or hyponyms. As an example, one page can present the term "exercises" and another page can use the term "learning activities" referring to the same concept. Another example is the case of pages with the terms "car" and "gear-box", which, in this approach, will have no relation (in fact, they are composite objects). These situations are treated in several different ways; in some research works, such as Loh et al (2000), concepts are used to describe the contents of documents (which may be Web pages). Concepts are higher-level abstractions that represent ideas, objects and events. They are described by a set of words or even by semantic networks containing synonyms, quasi-synonyms, lexical variations, plural, verb derivations, semantic related words, proper nouns, named entities and abbreviations, multi-words, lexical compounds or noun phrases. Each concept has only one set as a descriptor, but one term may be present in more than one descriptor set. Thus, associated to each term in a concept there must be a weight, describing the relative importance of the term in this concept.

Another limitation found in the traditional process is related with the usage data acquisition and treatment. In this case, the access patterns computed with data from the Web server logs or some other acquisition form can also have some important information for the mining process that is not correctly treated. Since the traditional systems work with the page view concepts, the common results are a cluster of pages or a frequent access pattern. However, the information is restricted to access only. None of the possible relations between the page views is taken into account. As stated before, some interesting conclusions can be obtained from the page views relations analysis. For example, a cluster of visited pages can be used to discover the relations between its pages.

The integration of semantic knowledge, as a way to overcome these limitations, can be found in works that are referred to "Semantic Web Mining", as described by Stumme (2002). The main objective is the integration of domain knowledge with the mining process. Web Usage Mining makes possible the capture and analysis of the behavior characteristics of Website users, for mechanisms directed toward personalization and adaptation (Koutri, 2004; Mobasher and Dai, 2005). This approach is improved with semantic information associated with the Web usage information. The semantic information can be used in the pre-processing stage, enriching the pattern generation, or in the adaptation process (Stume, 2002; Eirinaki, 2006).

The construction of models that are able to represent the knowledge, abilities, goals and preferences of users can be seen in Adaptive Hypermedia systems (Christopher, 2002; Petrelli, 2005; Wu, 2002). Many of these systems maintain identification interfaces and profile characterization of each user, while others use non-invasive techniques and aim to automatically obtain data for the generation and maintenance of the user model (Dolog, 2004). Morales (2006) describes an interesting approach aimed to acquire user models by a specific subsystem that applied semantic Web technologies. The system developed to model learners' behavior is closely coupled with a Web-based educational system and all the user actions are treated as events and related to content elements. This treatment has the objective to create beliefs about the learner that can be validated and stored in the model. In Cantador (2006) there is the description of a strategy to automatically cluster users' profiles based on an ontology that describes domain concepts. As these concepts are used, the system can generate several layers of clusters, each representing some group of users with particular interests.

Some interesting results may be achieved by the collaboration between systems. Since different systems can have partial information about the users, it is interesting to have some form of mediation or collaboration. The systems can benefit from enriching the stored User Model information. Some works are known in this field, as in Berkovsky (2006) and Musa (2005), which suggests the use of resources as Web-services and mediation approaches. Dolog (2004), Nejdl (2003) and Arroyo (2006) present a more detailed discussion about the possibilities of interoperability in personalization systems. The user model is implemented in diverse forms, using the semantic Web resources, as RDF for metadata description. In addition, this metadata annotation can be related to standards for learning modeling, such as PAPI

(IEEE LTSC, 2001) and IMS LIP (IMS, 2001). The application of semantic Web resources in the description of elements for the user models is proposed in Ounnas (2006), where some known standards as PAPI, IMS LIP and FOAF (FOAF, 2000) are studied and an extension to FOAF is proposed. From this extension, it is possible to relate information in these models.

In addition to user modeling there are known techniques for the construction of interfaces in a flexible manner and following the usage of these interfaces. These models and complementary information such as the application context, usage data covering user or user group interactions, and adaptation rules, amongst others, permit the identification of possible topics of interest, access restrictions and adaptations of content and format (DeBra, 2004; Brusilovsky, 2004). One example in this direction is the GLAM system (Jacquiot, 2006), that uses a layered model, in order to facilitate the adaptation. The main objective is to implement navigation adaptation, provided by means of actions selection.

The integration of usage information in combination with semantic information produces better results, as reported in the work of Mobasher (2002), where semantic information contained in the ontology of a Website, together with the usage data, is applied in the analysis and generation of clusters and association rules. Thus, the clusters and association rules generated allow correlating the relevant details of each section of the Website. The case study used is a film Website, and with this treatment, the user's choice of a page containing a film description can be associated to several possible actors of user interest, which would not be possible without the semantic description of the pages.

The usage information is also related with some structural data or annotation information. An example can be seen in the work described by Bateman (2006), where the annotation problem is addressed. This work suggests the collaborative annotation approach (CommonFolks) together with document annotation, in an e-learning context. The RDF and LOM patterns are applied. Another example is described in Bechofer (2006), related to conceptual browsing. Ontologies in OWL Language automatically relate hyperlinks from different Websites. This allows the use of the hyperlink structure of Websites in order to discover interesting relations. The metadata and reasoning components can dynamically relate resources.

The problem of content adaptation to users' preferences can also be treated with semantic knowledge, as demonstrated by Aroyo (2006). In this work, ontologies about a domain application allow inferring some specific relations associated with time or lexical relations. This facilitates the recommendations to the user, as it allows the conceptual navigation. Another example is the "Poncelet Project" (Habel, 2006) that applies an ontology describing the concepts in the educational material at the student's disposal. The ontology classifies the resources and relates it to concepts. Then it can provide multiple paths to different students. In addition, it may help in the administration of the resources.

Other works deal with the processing of specific characteristics involved in this process, such as the use of Description Logic techniques as an aid to the processing of semantic information (Esposito, 2004). There are also approaches to the more specific usage of semantic information (for example, similarity) in mining, as in the case of the *Semantically Similar Data Mining (SSDM)* algorithm (Vieira, 2005), for the mining of association rules taking into account synonym information. Mechanisms for the treatment of sets of data accessed by the user to construct a conceptual map with the objective of revealing their interests can also be observed (Zhong, 2006). There are methods for the identification of users based on the Web usage with the integration of this information with semantic information (Zhou, 2006; Jin, 2005).

In some works the employment of usage information integrated with semantic information is associated with the use of clustering techniques that take into account the set of concepts identified in a group of pages that has been previously reported as a commonly followed path with associative rules or as a cluster (Eirinaki, 2003; Esposito, 2004; Mobasher, 2005). In other cases, the ontology capabilities are used to provide semantic bridges between data resources, as RSS feeds. This can be seen in Conlan (2006), as domain ontologies are applied to personalize the exhibition of news items.

AN INTEGRATION APPROACH

The main purpose of this chapter consists in the description of the integration of Web usage information with semantic information. This integration makes it possible to obtain user classes that are associated with well-defined behavior, observed in the usage of Websites and, finally, to employ this information to generate adaptations without the need to identify specific users. An experiment that illustrates this approach is described. An open source Web Content Management system is used to implement the Web usage data acquisition and to generate the structure adaptations. The pre-processing and the Web Usage Mining steps were implemented independently, and a domain ontology provides the semantic description of the application. Details of the integration process are described below.

Web Usage Mining and Semantic Information Integration

The approach described here intends to be more complete, including not only the usage information adaptations. To accomplish this objective, the process also involves some semantic information regarding the Website structure and some complementary relations, such as content type, precedence and requisites. This information is maintained in a domain ontology, which is described below.

The usage information considered in this approach consists on the frequent sequential paths of the Website users. Considering a set $P = \{p_1, p_2, p_3, ..., p_n\}$ as the set of *n* pages in a Website, then the user access in a session allows the generation of a non empty set $L = \{l_1, l_2, l_3, ..., l_m\}$, where each l_i belong to P. A frequent sequential pattern is the set of repetitive accesses, observed some defined limits of occurrences. The identification of frequent sequential patterns in this work is implemented as an additional stage, using the algorithm known as Spade with the improvements described in the literature (Zaki, 2001; Leleu, 2003).

In the application used for the experiment, the published pages have a specific code that allows the recording of access information. This data is processed in a way that describes the path taken by each user in their visit to the Website (Oliveira, 2006). Figure 2 shows an example of the format and data applied in the access recording process. This format allows the recording of date, time and browser, the page URL, IP number and access parameter. The access origin is recorded in the “userid” element, generated by a cookie created at the first user access. The element “adapt” distinguishes the access between normal or suggested pages.

When the adaptation is based only in the usage information, these frequent sequential patterns are typically consulted at each user interaction in order to verify if the user path have some similarity with the considered patterns. In the case of a correct match, the system assumes that this user can have some interest for the subsequent pages in the pattern and they are suggested as structure adaptations. Figure 3 shows two different access patterns in a simplified Website structure: the first (a) is composed by the pages indicated by the set with continuous line. The second (b) is identified by the dashed-line set. When using the access information only, it is not possible to identify that the first represents a browsing over general

```

topics and the second represents the navigation inside a specific topic. This information is very important since it allows us to improve the adaptation process.

The ontology allows the definition of concepts, relations and restrictions regarding some application domain, which can be more general or specific. In this work, a more specific approach was chosen. In this case, the ontology is also known as a "domain ontology" and one of its advantages is the possibility of having a more precise mapping of the important concepts and its relations, given the target domain. This choice demands the ontology to be reviewed and rewritten to each (new) application domain.

An experiment to allow the validation of this approach was developed in the educational field. The domain ontology created had as objective to describe relevant concepts to the educational field. The same approach can be applied to different areas, with specific ontologies. The ontology was manually constructed by application domain experts using the Protégé ontology editor (Protégé, 2007), with the OWL language. This representation form facilitates posterior manipulation. In this case, part of the information described in the ontology can be seen in Figure 4 and represents the content available on a Website with educational material. There it is possible to observe the relations between "topic" and "course". The relations "part_of" and "composed_of" indicates the type of the composition. The relations "has_requisite" or "is_requisite_of" indicate dependency between the topics of one course. The relation "contain" allows qualification of each component in the Website. The relation between the Website and the ontol-

Figure 3. Some access patterns and its interpretation

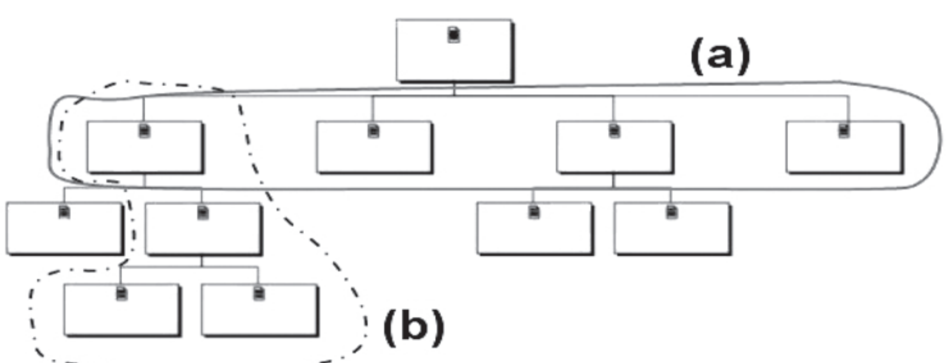

Figure 4. Part of the domain ontology used in the experiment

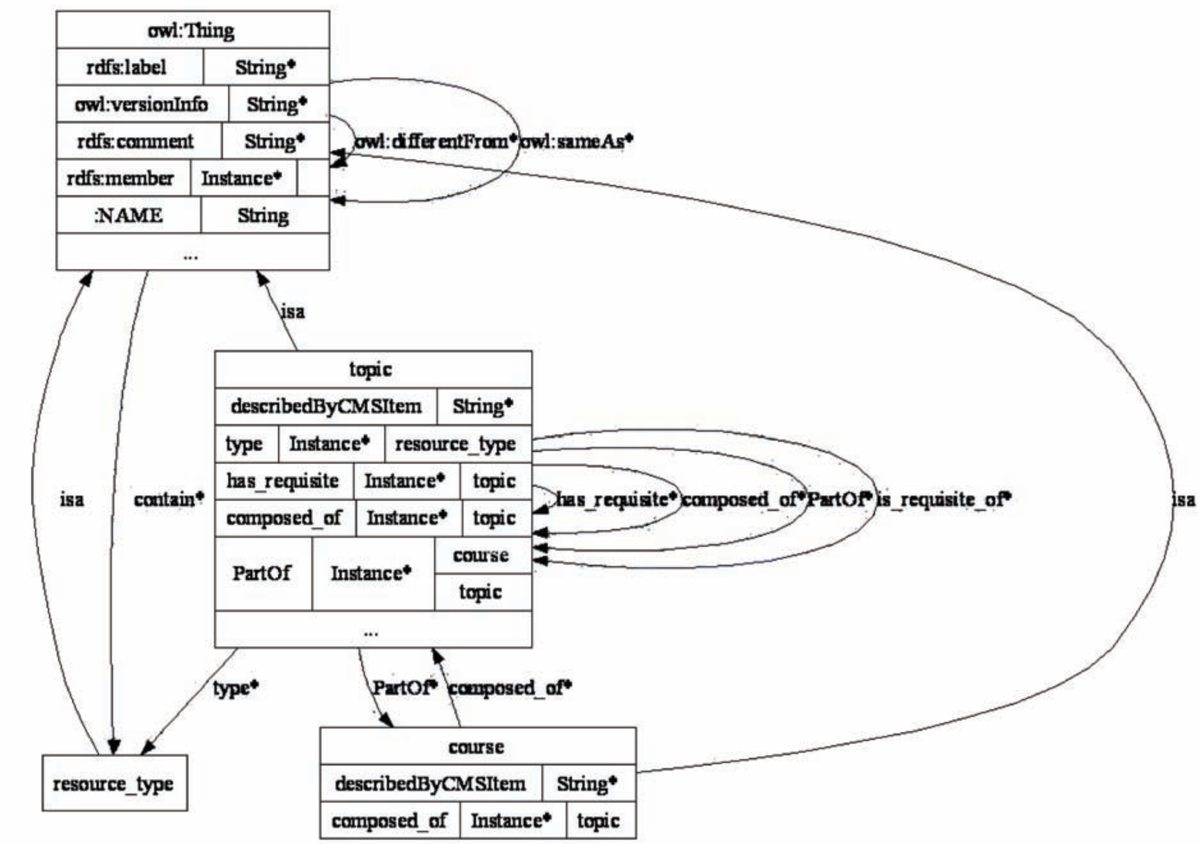

ogy is established by the semantic annotation of the Website elements. Each page of the Website is described as an ontology instance, along with the necessary relations. These instances are used in the integration process along with the usage information, as described below.

The instances in the ontology can be manipulated by inference mechanisms or by query languages, such as SPARQL language (Seaborne, 2007), which was the case in this work. The SPARQL language verifies the occurrence of interesting relations in the ontology instances. As an example, it is possible to identify, given a specific instance, all the relations associated to it. Also it is possible to recover, given a specific property, all the instances related to it. Finally, it is possible to discover all the relations that exist between two known instances.

To illustrate how the SPARQL language and the semantic annotation were used in this work, we will use Figure 5 that illustrates the description of one element of the application domain ontology.

Figure 5 shows part of the OWL representation of the instances in the ontology. The items "*T05_ACTIVITIES*" and "*T05_01_MENU*" are identified respectively as "*ID_24*" and "*ID_25*", based on the RDF ID element. This identification relates the elements to the corresponding pages in the Website. The "*composed_of*" relation defines the hierarchy between the items. The property "*describedbyCMSItem*" allows the semantic annotation of the contents, as they are stored in the Web Content Management System applied in the experiment. The relation "*part_of*" identifies the topic described as "ID_24" as part

Figure 5. Part of the domain ontology instances

</topic>
```

of the course titled “Database”. This information can be accessed using the following SPARQL statements.

Figure 6 illustrates some possibilities for the identification of relations using the SPARQL language. The topic identifiers in the ontology match the browsing parameters used in the Website navigation. This allows the integration between the access information and the ontology information, in queries performed with the previously identified frequent sequential patterns. The first example (a) identifies all relations and instances associated with the two topics indicated (“ID_24” and “ID_25”). The second example (b) recovers all the relations between these two topics. The outcome of these queries allows the identification of the context that is not accessible from the usage patterns alone. This context is applied to identify users’ stereotypes, which are then associated to specific adaptation rules.

The result is the identification of more interesting patterns, related both with the usage and with the Website structure. By associating these patterns with specific rules, adaptations that are more expressive can be reached. Some examples of these results are the identification of users looking for specific topics, general view of the Website or complementary contents.

Figure 7 illustrates this process in a general form. The adaptation stage receives information from the domain ontology as well, in addition to the frequent sequential patterns already obtained from the processing of the access log data. With these two sources of information, it is possible not only to identify the page access sequences, but also to identify the concepts present in each page and their relationship. From the interaction with the

```

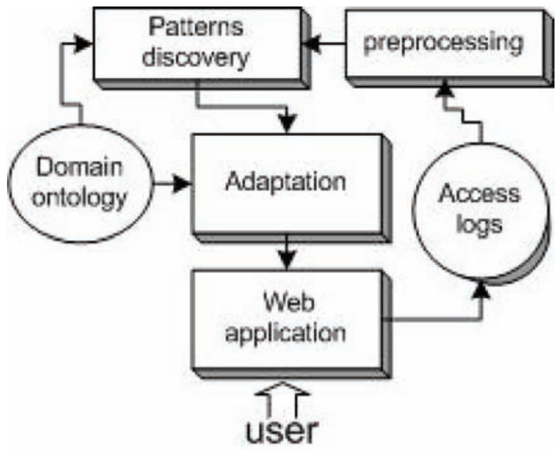
Figure 7. Integration of semantic information with Web Usage Mining



user, the Web application collects the usage data, storing them in the 'access logs' component.

The pre-processing integrates the usage information, making it available to the next stage, the patterns discovery. After their validation, these patterns are available for the adaptation component, which interacts with the Web application generating adaptations of the structure of the Web pages. This action takes into account the existence of a domain ontology for the application in question.

Structure and Content Adaptation

The information originated in the observed frequent sequential patterns is added to the original structure of the Website. Following the information already collected and processed, the system has a description of frequent sequential paths and specific relationships derived from the domain ontology. Based on the behavior observed from a user session the information is employed as complement to the original structure of the site and is published in specific areas of the interface. Thus, the pages accessed by the user are correlated by frequent sequential patterns. The identification that a certain number of pages accessed during a user session belong to a pattern can be assumed to indicate that the user in question is part of a group of users of the Website that share a specific content interest, and found this set of pages.

The identification of frequent sequential paths is applied in this work to minimize the need for specific rules for the generation of adaptation. In some systems, and particularly in those directed toward education, it is necessary to identify users and even to record the actions they make on the system. As consequence, in these cases it can be easy to specify the adaptation mechanism using rules (Paramythis, 2005). In the experiment that we have carried out, the identification of the users and their details is avoided, as was the use of this information to generate rules. An argument to justify this approach can be found in the behavior of users of Websites with domains different to those directed toward education, where in general there exists no desire to provide identification information.

The pre-processing of usage data and the generation of patterns is carried out periodically. During the user sessions, the system detects, from a recent access history that includes only accesses made in the current session, any coincidence of the observed behavior with the behavior patterns previously established and, if there exists such coincidence, carries out the associated adaptation.

In these cases, as covered in the experiment, the adaptation was composed of alterations applied to the structure of the resulting page with the addition of new navigation possibilities derived from the patterns that have been established. Content adaptation could be carried out by the addition of material related to the content being accessed on the basis of some relationship given in the ontological description. The semantic annotation of the content permits the identification of specific situations, from the identification of the type of complementary resources.

Experimental Results

Adaptive Hypermedia systems can pose several problems when the question is the performance and quality evaluation. The adaptations implemented can be associated with quality attributes and with efficiency parameters. In this case, since the main objective of this work is the identification of the useful Website adaptations, based on users' stereotypes related to a set of users, some tests were conducted in order to evaluate the quantity of generated adaptations and the quantity of accesses to these suggested adaptations.

The experiment in discussion was carried out over a period of six months during which the material was available for access, with the necessary information for the adaptation being generated.

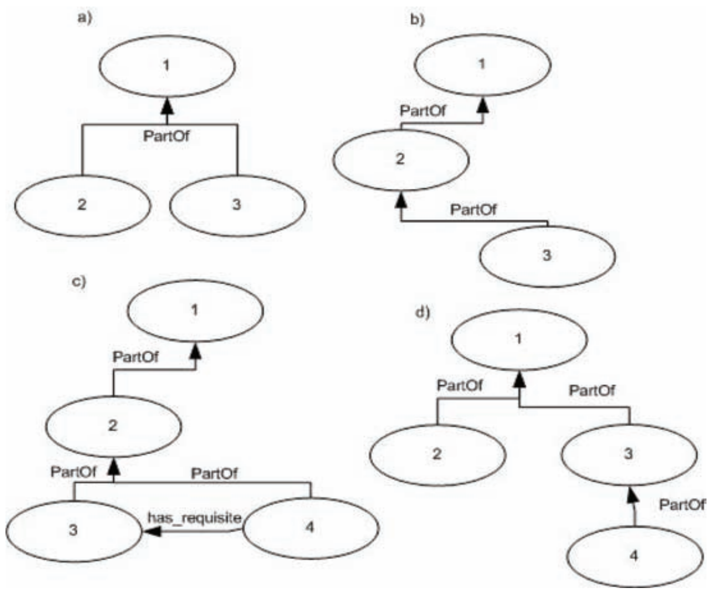
The results obtained indicate that some frequent patterns were related to specific behavior. One of these cases is associated to the overall navigation, where the user accesses the main topics available in the Website structure. This information is obtained from browsing frequent patterns that returns, when integrated with the semantic information described in the domain ontology, a relationship with an upper concept, usually the Website initial content. The kind of relation verified in the ontology in this case is mostly the "part_of". Another frequent case is the situation in which the items in the frequent pattern are related mostly with the "part of" relation, but in a way that an antecedent and subsequent item are associated. In this situation, the behavior detected is described as a navigation in which the user accesses the related and internal items of one specific topic.

Some of these situations are identified below and can be used as examples of the improvements obtained with the approach. The analysis of different frequent sequential patterns, with the same number of elements, allows the identification of different contexts. These contexts can only be distinguished when the domain ontology relations are used together with usage information. Some examples are summarized in Figure 8. In this figure, it is possible to identify elements that correspond to frequent patterns, with a number indicating their access order. The arcs between the elements indicate the ontology relations found for the items. Comparing the items "a" and "b", it can be seen that the first item ("a") is the representation of a browsing in the same level of the Website, the equivalent of a general view of the contents in this level. However, the second item ("b") indicates the access to more detailed information in one specific Website topic.

Based on this identified context, different adaptations procedures can be chosen. Another example of different contexts discovery can also be observed (items "c" and "d"). In the first case ("c"), the browsing started in a more general level and was directed to a more detailed level. In the second case ("d") there is more activity browsing in a general level, followed by the choice of a more detailed level.

The suggested adaptations are monitored and the access to these items can be compared with the normal Website items. In this case, the results indicate a useful set of adaptations generated. The proposed method can generate valuable information by relating the Web usage data and the semantic information. It is also possible to insert of new relations in the domain ontology, in a way that can be appropriated and effective to different application domains.

Figure 8. Semantic contexts obtained



CONCLUSION

This chapter presented an approach for the acquisition of user stereotypes based on Web Usage Mining and domain ontologies. In this case, the domain ontology describes important relations for the application. The relations in the ontology are combined with the usage patterns obtained by Web Mining techniques. The integration of semantic information with usage information was described and some related works were presented, in order to illustrate the possibilities of better identification of the interests and needs of a typical user with these resources.

The cognitive overload observed in the process of Internet users searching for information can be related to the difficulties of automatic acquisition of needed information. As the Internet standards were developed to human usage, there is the necessity of more adequate resources to the structured and more formal description of the documents and contents. In addition, there is the necessity for formal mechanisms to documents annotations. This allows the use of metadata and gives support to a great number of possible applications that would benefit from this information. The operations that become possible with a structured and properly identified (annotated) document are far more interesting than those possible with non-structured or un-annotated documents. Some difficulties in this case are observed in the annotation process, which can be manual and dependent on users' effort, or can be automatic and rely on Text Mining techniques. Resources such as ontologies and inference mechanisms can improve this scenario, with even better possibilities, as they can describe domain applications concepts and its relations. In this case, the knowledge described in ontologies can be associated with the existing documents for better manipulation.

These semantic resources are also used in a great number of experimental applications, but there are also diverse industrial initiatives. The Adaptive Hypermedia applications are among those that benefit from these resources. This can be observed in several aspects, as in the application descriptions, interface generation, user and context models construction or adaptation mechanism.

Some of the tasks of Adaptive Hypermedia applications are carried out with information generated from fields as Web Usage Mining. Specifically the user stereotype can be enriched by observing significant access patterns, related to the pages of a Website, obtained from the user navigation pattern. In this sense, these patterns can be treated as evidences of specific needs or goals, and then used to identify classes of users. It has also been shown that the use of a domain ontology, in which the pages can be associated to specific concepts or stages of repetitive processes on the Website, is more general than just the use of access information, without the related semantic information. That can justify the integration of Web Mining, ontology description and semantic integration possibilities. The requirements for the semantic knowledge and usage information integration are discussed and related with Adaptive Hypermedia application. There are even better possibilities for improvements when the application has a more formal description, such as an ontology, and associated to specific models that help, for example, in the identification of concepts associated to the application domain or to stages of routine tasks.

The handling of a user model and the direct identification of a specific user makes adequate results possible, because information concerning their interests, knowledge and goals are taken into account. Despite that, it is considered important to also evaluate the possibilities that arise from the data collection being uncoupled from a specific user. With this procedure, repetitive behavior is identified, which can also serve to identify goals and interests, with no specific user identification. In many application areas, it is not feasible or desired to obtain the user identification.

KEY TERMS

Adaptive Hypermedia: Approach to automatic personalization.

Domain Ontologies: Description of concepts and relations regarding some knowledge field.

Personalization: Process that adjust the results obtained by users when accessing Web systems.

Semantic Web: Set of resources intended to improve the actual possibilities of Web applications.

User Profile: Set of information regarding user preferences, necessities and knowledge.

Web Systems: Any application designed to be used on the Web.

Web Usage Mining: Set of techniques to generate patterns and discover knowledge from the web usage data.

This work was previously published in Handbook of Research on Web Log Analysis, edited by B. Jansen; A. Spink; I. Taksa, pp. 284-306, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 5.13
Improving Online Readability in a Web 2.0 Context

John Paul Loucky
Seinan Jogakuin University, Japan

ABSTRACT

This study describes a task-based assessment (TBA) approach to teaching reading and writing online. It then analyzes key factors emerging from the results of implementing this approach with graduate engineering students in Japan. It is argued that these factors should be considered when designing or assessing any online reading or writing course for ESL/EFL students. The findings of this study are especially relevant to task-based approaches and technical or pedagogical innovations which can help foster more effective and enjoyable learning for teachers and students in blended learning environments. It is hoped that this discussion can serve as a model of what can be done to enhance online EAP/ESP/ETP courses, as well as any other online reading or writing course being designed for speakers and readers of languages other than English. The goal in this chapter is to summarize research aimed at integrating some of the most useful Web sites for English language learning into a user-friendly system for optimal online vocabulary development — which could be self-monitored by students as well as tracked by teachers via a course management system.

DOI: 10.4018/978-1-60566-190-2.ch021

INTRODUCTION

The emergence of new types of electronic media such as blogs, wikis, mobile phones and social networking sites is having a profound effect on the way people communicate. This is especially true of written communication and therefore as a consequence also greatly affects the way people read and consume information. The high levels of familiarity that today's students exhibit vis-à-vis these technologies is set to have profound effects on the ways that foreign languages are taught in a Web 2.0 context. If students of English as a Foreign Language cannot comprehend the high level of vocabulary and technological jargon found online, messages will not be understood and learning will be impeded. Given the challenge presented by the new landscape of Web 2.0 communications, there are two main objectives in this chapter:

1. To examine how best to assess and improve the readability of any website or application. Furthermore to indicate how a series of critical linkages can be formed to better integrate listening, glossing and translation so as to empower learners to better comprehend any Internet application or location.
2. Using the Virtual Language Education Links Library, known as the World CALL Language Links Library (Loucky, 2008), this chapter aims to identify which kinds of language learning sites and Web 2.0 functions are most helpful to Japanese graduate students vis-à-vis improving their online English reading and vocabulary skills. This World CALL Directory (found at www.CALL4ALL.us) is a Free/Open Source Language Education Resource Repository. Its aim is to serve as a Virtual Encyclopedia of all major language learning links, Web dictionaries and Computer-Assisted Language Learning organizations in the world.

In an age where multi-literacy and foreign language literacy in multimedia environments are becoming increasingly more important, teachers need to be able to understand and use more CALL technologies for efficient reading and vocabulary assessment to produce effective and enjoyable language development. The need for quick, easy and reliable readability checking for English reading texts has recently become more pronounced. Whether assessing print, online fiction or nonfiction texts for either Extensive or Intensive Reading (ER or IR) use, language learners and teachers are in real need of helpful, user-friendly ways of assessing the reading levels of texts.

For over 50 years, readability formulas have been used to help guide students to books at their appropriate level of reading and interest. Briefly stated, it is very important for ESL/EFL teachers to be able to individually test their students to determine their actual reading instructional level. EFL teachers using extensive reading are still in a quandary about how to arrive at commonly understood reading levels for various publishers, who do not use a uniform system. Before deciding what reading methods or materials to use, English reading teachers need to realize that three different kinds of reading levels are most crucial to understand. These three categories of reading ability are 1) Frustration Level, to be avoided; 2) Instructional Level, which Intensive Reading and classwork may be done at; and 3) Independent Level, which is appropriate for Free or Extensive Reading. Table 1, adapted from Loucky (1996, p. 301) and (Ekwall, 1976, p. 267), illustrates what these different levels involve.

Three other types of reading levels should be considered and compared when trying to best match texts or books to students:

1. The readability level of a text or a book's grade level: a particular text's reading difficulty level has most commonly been measured by a given readability formula (e.g. Flesch Reading Ease, Flesch Kincaid Grade Level).
2. The interest and maturity level of a book or text's ideas and content (usually grouped by

Table 1. Reading level criteria

Reading Level	Word Recognition	Comprehension %
Free or Independent	98 - 99% or more	90% or more
Instructional	95% - 98/99%*	75 Ideal (51 - 89%)
Frustration	90% or less	Under 50%

Note. The asterisk indicates not more than 1/20 unknown words.

Lower Grades, Middle Grades and Upper Grades).
3. The individual reading and maturity level of each student.

Ekwall's (1976) classic reading education text listed approximately 50 standardized reading tests, all based on using such formulae for estimating American students' average independent reading level. A learner's independent reading level may be defined as the most difficult level of text s/he can comprehend alone without using a dictionary or another's help. Loucky (1994, 1996, 1997, 2003, 2006a) has used these kinds of tests to assess several thousand Japanese college students' English reading levels. Based on nearly two decades of research, it has been possible to identify consistent patterns that are useful for language teachers to know, especially those wanting to tailor the level of required or free readings to individually appropriate levels. Once each learner's independent reading level has been determined and compared to the average for particular grade levels, each student can be guided to materials that are at his or her appropriate instructional level. This is normally defined as 1-2 grades above their free or independent reading level. Frustration levels beyond that should be avoided at all costs. Today there are many proponents of stress free-reading, or fluent, independent reading, whereas instructional level reading may be reserved for practice of particular reading skills during Intensive Reading classes.

Palmer distinguished extensive from intensive reading (1968, p. 137). Intensive reading tends to teach reading as a set of component skills and usually refers to careful or close reading (or translation) of shorter, more difficult foreign language texts with the goal of deeper and more detailed understanding. Texts are studied intensively in order to introduce and practice reading skills that are distinct. By contrast, Bamford and Day (1997) characterize free or extensive reading as being:

generally associated with reading large amounts with the aim of getting an overall understanding of the material. Readers are more concerned with the meaning of the text than the meaning of individual words or sentences … Extensive reading as an approach to teaching reading may be thought of in terms of purpose or outcome … It can also be viewed as a teaching procedure, as when Stephen Krashen (1993) terms it free voluntary reading, or when teachers give students time for in-class Sustained Silent Reading (SSR) — a period of 20 minutes, for example, when students and teacher quietly and independently read self-selected material … No matter how sophisticated the teaching profession's understanding of and ability to teach the reading process, until students read in quantity, they will not become fluent readers. (n.p.)

The two main elements that determine a student's reading rate are the difficulty or readability of a text and the purpose of reading it. Readability formulas have generally been a combination of two factors: 1) a measure of a text's word difficulty level, and 2) a measure of a text's sentence complexity. Raygor and Raygor (1985) have graphed readability estimates showing that a text's grade level is based on both its total number of sentences and its number of long or difficult words. Readability formulas measure a text's word difficulty and sentence complexity as follows: "Word difficulty is measured by word length or frequency. … Sentence complexity or syntactical difficulty is usually measured using the average number of words in the sentences" (p. 192). Two other important principles deduced from readability studies are also evident:

1. Readability formulas use objective measurements to analyze text and predict which materials can be comprehended by individual readers as long as they are used to assess both text and learner appropriately.

2. Students generally show the most reading improvement if they regularly practice reading within a range of difficulty that is neither too challenging (known as the *frustration level*) nor too easy (their *independent reading level*). While all readability formulas are based on analyzing some aspects of a text or book's difficulty, they cannot indicate the suitability of a particular text's content or literary merit for particular learners. The choice to read is usually a decision best left to educators and parents in consultation with the learners themselves.

Space constraints do not permit a thorough discussion of a new type of technology affecting reading, portable digital devices such as Amazon's Kindle or Sony's e-Reader, though they will clearly affect the way texts and books are read in the years ahead. A number of thinkers have already predicted that only devices that are wired to the Internet will have a long-term appeal, as the web will enable them to integrate and use free online glossing, storage, review and translation tools. Proprietary devices such as Kindle are currently limited by copyright protection, and can only read Digital Rights Management (DRM) content from Amazon. As Amazon mainly sells publishers' books, their central interest will be commercial rather than educational, thus creating a natural conflict of interest in terms of the real costs of overheads and royalties (for author and agent). All of this will continue to drive the price of e-books too high for most normal consumers. Many now believe that globalization includes the ideal of making generic knowledge freely available to as many people as possible, and making computers as cheaply available as possible, as evidenced by the MIT-sponsored One Laptop Per Child Foundation (OLPC). Those supporting these general educational ideals would no doubt agree with OLPC's five core principles:

1. Child ownership
2. Low ages
3. Saturation
4. Connection
5. Free and open source (OLPC, 2008, n.p.)

With such a contrast of principles and features available, and the substantially cheaper online costs and greater benefits available through open source online materials, it is not hard to predict who will win the next Information Revolution.

Accelerated Reader is another online commercial learning information system designed to help teachers manage and monitor their learners' reading practice. Renaissance Learning offers a set of teaching practices online; information on judging the suitability of books; articles on readability and how to use it in the classroom. Most Extensive Reading (ER) is done at the free or independent reading level. However, there is not only a need for more careful, individualized testing of what exactly constitutes each student's free-reading level, particularly when it comes to foreign or second language readers. Those having non-European native scripts are often more challenged and frustrated than native readers would be, due to having even more differences between the expectations of that second language system, as compared with reading their own native text. In addition, the complexities and different skills required to read online text fluently make it a rather different species of reading, whether in L1 or L2. Thus, the need for a strategy to better assess online as well as print texts in more uniform ways is becoming more apparent to reading teachers worldwide.

LITERATURE REVIEW

First, it is important to define Web 2.0 with reference to O'Reilly. Then we will contrast this definition with emerging definitions of nascent

Web 3.0. From O'Reilly's definition we can see that rather than merely being a new technology, Web 2.0 is characterized by a new mindset, or attitude towards the use of the Internet:

Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually-updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an "architecture of participation," and going beyond the page metaphor of Web 1.0 to deliver rich user experiences. (O'Reilly, 2005)

Secondly, there are distinct differences both in how technologies are seen and used in successive generations of the Web, just as there are clear differences between reading print and online reading. Although Web 1.0 took people to information, Web 2.0 is involving people in information and knowledge construction, following a constructivist philosophy, creating what has become known as "an architecture of participation" (O'Reilly, 2004). While typical definitions characterizing this new style of online participatory information-gathering and meaning-construction generally range from positive to almost ecstatic hype, there are definite dangers and downsides for businesses, parents and public institutions to be aware of.

Devo (2008) explains both the upside and downside of emerging Web 2.0 tele-communication applications, which have been spreading like viruses. These include wikis, blogs, mash-ups, folksonomies, social bookmarking and podcasts:

Neatly labelled Web 2.0, zealous users appear to see bilateral and multi-lateral discourse with others, using collaborative and social networking, as not so much good as utterly compulsive. For the business world, there is a real concern emerging on the coat tails of the social explosion — a concern that employees are now spending so much time networking, that business could become a secondary consideration. (n.p.)

So what do we mean by Web 2.0? Devo (2008) summarizes Smee, marketing director of the Web Technology Group, who notes that this catch-all term for online social networking is still much misunderstood:

"In a way, the Web 2.0 label is a buzzword and there are lots of different interpretations of what it means," she says. "My personal view is that it is what Web 1.0 was always meant to be, which is simply to enable knowledge sharing. Putting user-generated content in the way of blogs on to the web is just the next step. It is an evolutionary process and not a case of yesterday we had Web 1.0, today we magically have Web 2.0." (n.p.)

Others have called this basic change of focus seen in many Web 2.0 applications a major paradigm or head-shift, an embracing of a freer, more two-way "E-democratic" mutual sharing of information by both user and provider. As such, it is seen as being most useful for e-Learning and sharing of discussion on social, political economic and human rights issues, as well as the full gamut of human discourse. Space limitations prohibit a full discussion of these issues, but groups like Involve (www.involving.org) go into detail about past failures and future hopes from using these new participatory online technologies more intelligently and democratically (Bryant & Wilcox, n.d.).

Comparing three generations of Internet website design and usage, it is possible to contrast Web 1.0 (read-only web) and 2.0 (read-write web) with what is now perceived as the Internet's future, Web 3.0 — a term which refers to the emergence of users who can modify substantial parts of the site or web-based resource. Others foresee Web

3.0 as an evolution of Internet use and interaction where it becomes a database in which information is accessible by various non-browser applications, not only by different browsers as at present. What is important for improving online reading and language learning in such an environment is to make sure that whatever browser or generation of Internet is being used, learners have instant access to a wide variety of glossing and translation engines, Text-to-Speech listening support, review test generation and language development programs that are needed to maximize their target language vocabulary learning recognition and use. Some others have seen the term Web 2.0 as just a marketing term, contrasting it with a more 3-Dimensional Web, which leverages various artificial intelligences, the Semantic and Geospatial Webs, into what Berners-Lee called a Giant Global Graph (GGG) (Dignan, Perlow, & Steinert-Threlkeld, 2007). He sees Web 3.0 as more of a "Social Graph," representing its third great conceptual leap — from net to web to graph (n.p.). Probably the best comparison of these second and third generations of Internet use is in Spivack's (2006) article called "The Third Generation Web is Coming." There he discusses its eight major characteristics, as well as offering the clearest definitions and distinctions between the first three generations of the web.

Finally, we can gain a good prediction of how the Internet will develop in the third decade of the Web (2010–2020), during which Spivack (2006) suggests that several major complementary technology trends will reach new levels of maturity simultaneously. His expanded definition of Web 3.0 envisions the third-generation of the Web as being enabled by a convergence of several key emerging technology trends. He predicted these new features of Web 3.0 would include:

1. The transformation of the Web from a network of separately siloed applications and content repositories into a more seamless and inter-operable whole.
2. Ubiquitous connectivity, broadband adoption, mobile Internet access and mobile devices.
3. Network computing, software-as-a-service business models, Web services inter-operability, distributed computing.
4. Open technologies, open APIs and protocols, open data formats, open-source software platforms and open data (e.g. Creative Commons, Open Data License).
5. Open identity, OpenID, open reputation, roaming portable identity and personal data.
6. The intelligent web, Semantic Web technologies such as RDF, OWL, SWRL, SPARQL, GRDDL, semantic application platforms, and statement-based datastores.
7. Distributed databases, the "World Wide Database" (enabled by Semantic Web technologies).
8. Intelligent applications, natural language processing, machine learning, machine reasoning, autonomous agents. (Wikipedia, 2008a, n.p.)

According to O'Reilly and Battelle (Wikipedia, 2008b), an architecture of participation where users can contribute website content creates network effects. Thus, in order to most effectively harness the power of the Internet for language education following a Web 2.0 paradigm, teachers need to learn to leverage the power of its "Long Tail" to develop "an architecture of participation where users can contribute website content [that] creates network effects" (n.p.). Since data becomes a driving force in Web 2.0, and even more so in Web 3.0 models, language teachers need to know and focus on which vocabulary (or lexical corpus and collocations) and grammatical structures their learners need to be exposed to in order to reach higher levels of fluency.

How can this be done most effectively to enhance online vocabulary and related reading comprehension development and language learning? This can be accomplished by integrating various programs needed by language teachers and learners into a more seamless whole, as is being done at some more innovative CALL sites. WordChamp.com, for example, combines many automatic functions, such as auto-glossing, auto-archiving, audio and visual enhancement, auto-uploading and test generation to provide a complete Course Management System (CMS) for courses. It also established peer-to-peer communication between users from 137 language backgrounds from any point in the world, using both an internal Instant Messenger system and the possibility of file-sharing. Learners' or teachers' vocabulary files can also be uploaded online or use mobile devices easily.

So perhaps the best way to enhance language learning using the Web is by finding and using good programs like these and by building more open source language learning communities online, which encourage maximum active participation and collaboration in the exchange for authentic communication between learners and speakers/readers of various languages. This means teachers need to embrace the web as a platform and aim to use its strengths (global audiences and collaborative learning, for example). Rather than fight or ignore the Web, teachers and researchers should aim to build applications and services around its unique features, especially its ability to enable users to both create and share content across various networks and boundaries.

USING READABILITY ENHANCING PROGRAMS

Chun (2006) examined CALL technologies for L2 reading, and compared the effect of providing some type of glosses upon improvements in vocabulary acquisition and reading comprehension. As she stated, results from CALL studies should always specify participants' L2 language proficiency, and cannot be generalized to all L2 learners. Chun noted various implications for online reading instruction from Grabe's (2004) reading research. Her rationale for having language learners use electronic and multimedia glosses is that:

> *They aid readers in performing the bottom-up function of recognizing and/or understanding individual lexical items, which in turn frees up working memory capacity and allows more of the reader's attention to go toward the top-down processes of reading comprehension. … Online glossing is thought to provide fast and easy access to the meanings of unknown words and to compensate for insufficiently automatic lower level processes and thus allows the reader to attend to higher level processes.* (Chun, 2006. p. 70)

There is still a lack of extensive, quality research about how to improve both skills and assessment of reading online, and more generally, how to improve the readability of web pages for learners from various backgrounds. Taking students to the Web should serve the double purpose of helping them to learn to read better either in their native (L1) or target foreign language (TL/L2), while simultaneously helping them to improve their acquisition of essential electronic literacy skills needed to cope with content and/or academic courses. While some of this delay seems caused by resistance to educational and technical change, instructors also seem to still lack clear pedagogical or theoretical models of reading online. Better understanding and application of Web 2.0 and Web 3.0 technologies can certainly help to design more effective models for successful interactive online reading and language learning communities. Another example is *Qnext*, a site which promises to be one of the fastest growing phenomena since *Facebook*, as it enables users to integrate and communicate with any Instant Messenger program, and share any and all files online with anyone else anywhere, free of charge.

Indeed, the educational community does seem to be a bit slow in making the transition from traditional text-based reading to online reading, which requires the teaching and learning of different perceptual approaches in both L2 text comprehension, as well as in lexical acquisition and processing strategies. Two major book readability grading systems already exist online:

1. Renaissance Learning's program which features the "Accelerated Reader" system with computerized quizzes and record tracking for more than 22,000 titles, also known as ATOS.
2. Touchtone Applied Science Associates' (TASA) Depth of Reading Power (DRP) program. TASA Literacy Online uses a scale of 0-100 in their own measure of text level and student reading level. They call these levels Degrees of Reading Power (DRP). They have also designed and used tests of vocabulary in context called Degrees of Word Meaning (DWM). Perhaps the best part of this vocabulary level testing scheme is that they provide a brief Conversion Table, which helps teachers convert these DWM vocabulary level scores into an estimated size of reading vocabulary.

Degrees of Word Meaning scores range from 850 (the equivalent to knowing over 157,000 words), to less than 300 (indicating that such a test taker knows 100 or fewer English words). Their products for educational assessment are numerous and include the Degrees of Reading Power (DRP) tests as well as online programs and steps for estimating both reading levels or the readability of any text or book.

Renaissance Learning is a commercial educational program for schools, with readability measures available for approximately 30,000 books. Anyone can estimate the level of any book by selecting three 150-word passages and emailing them to the site. Even more interesting is that users can enter three such samples in MS Word and freely analyze their level via Word Count with Readability measures activated.

Many reading teachers are looking for these kinds of helpful services to assess any text's readability. To help meet this need, Loucky (2005) developed an integrated English for Advanced/Specific/Technical Purposes online course, combining various online Reading Labs, for Japanese students. Its final Listening-enhanced Step for those having Natural Voice Reader or other text-recognition software includes:

1. Listen to the text read electronically.
2. Learners should try to understand its meaning phrase by phrase, paragraph by paragraph in whole sense units, not just reading word by word.

Where reading on screen differs most, however, is in the areas that Taylor (2005) notes. First, much more skimming and scanning is used. In fact 79% of Web users were found to be using these skills rather than reading word for word. This finding has huge implications for teaching the skills most needed for efficient online reading. Clearly both web writers and language teachers wanting to use online resources most effectively need to be aware of these major reading differences, as well as demonstrate sensitivity to the foreign readers for whom reading L2 texts designed for natives is often impossible or highly frustrating. Some studies, such as those done by Sun Microsystems Science Office have claimed that "Reading from a computer screen is 25% slower than reading from paper" (Nielsen, Schemenaur, & Fox, 1994). Many differences in reading rates have also been noted between on-screen reading using a monitor versus the printed page. Some of these differences may be due to differences in the text delivery system, in the layout, number of columns and length, etc. Other distractions to the reading task online may be caused by the need to use scrolling, hyperlinks or pop-up ads. All these factors may impede one's reading on a digital screen. Once practiced and proficient at reading online, however, probably the opposite is true for fluent readers. Much more research comparing skills, speed and accuracy levels of online versus print text reading is needed on readers at various levels, both native and non-native speakers, before such general claims can be accepted.

Teachers trying to use CALL or e-learning as well as web writers need to write in clear chunks and make text scannable at a glance, since an eye-tracking study done by the Stanford and Poynter Institute found that online readers often focus narrowly upon headlines and summaries (78% of their eye attention was here). Since online readers must use more skimming and scanning to get the gist and locate relevant information quickly, and Web distractions can make their speed 25% slower, these principles recommended by Taylor (2005) can help improve the readability of web copy.

Online authors must aim to write web materials clearly and succinctly in summary style. As Taylor (2005) states, a Web materials writer should think like a graphic artist, treating "each page like a painting that is framed by the computer on this electronic canvas [where there] are elements that you, the artist, must weave together, linearly, to form a coherent whole that can be accessed with little or no reading. … Web writing places a premium on good organization of content and devices [navigational bars or buttons] that clarify the content's organization to the web user" (n.p.). Other principles advanced by Taylor also include:

1. Invert the pyramid of information, using journalism's major headlines and summary first style.
2. Compress information and be more concise, so reduce word count by at least 50%.
3. Make one paragraph carry one major idea.
4. Make each page's text stand alone, since users can enter through hyperlinks from various places.
5. Provide needed hyperlinks, using keywords as titles/headings. In other words, make useful and relevant links to helpful resources, both within a site as well as to other sites.

Some important new principles come into play with a Web 2.0 approach to information dissemination. These include a user-centered mentality, where more readable and comprehensible information should be made available to users, when, where and in forms that they need and can readily use. Since Web 2.0 enables more people to share and author information by means such as text and audio file-sharing, podcasting, photo-sharing, blogging, etc., such information can become more personally relevant and meaningful to specific user groups. On the other hand, copyright, expensive monolithic publication systems and "Information Gate-Keepers" will tend to be by-passed or disintegrate, while information-sharing technologies give users more direct access to publically available, Web-visible learning resources. But how can Internet resources be used most effectively to improve online reading and language development? This is the key question under discussion in this chapter.

Having established a better understanding of the major differences between reading print text versus on-screen text, teachers and web writers can implement better solutions for the special needs of L2 readers. Beside these clear reading differences, others have only become apparent in recent research. As Taylor (2005) noted, "In both cases, it's essential for web writers to be aware of the differences between the world of linear text flowing like a river, and the fragmented world of hypertext on a pixel screen. The most successful web writers have honed in on the key differences between writing for print and writing for the web" (n.p.).

Finally, we must remember that the Web is rigorously democratic, in that the user is in much more control of an online, interactive learning experience, than when reading print text, or other more passive, non-responsive mass media. The Internet is a self-access mode of learning, but a majority of learners may not be "self-starters," and especially foreign language learners can be quite intimidated and feel threatened by L2 online materials. Thus we need to provide a variety of levels (with both authentic and simplified text), entry points, and plenty of multi-media and bilingual assistance to aid and encourage their language learning.

Many of these factors are considered by Coll (2002), Loucky (2002, 2005, 2006a, 2006b), and Akbulut's (2006) studies of learning in hypertext environments. Online reading seems to discourage word-for-word reading, since print readers can hold the entire document in their hands at once, whereas a web document must be called up one page at a time, either by the action of scrolling or by using hyperlinks. Even better for discouraging single word reading, however, are reading pacers, some of which can be set by the learner to at least three different speeds to adjust for their own comfort and ability level. This type of on-screen reading function is essential, for at least some Web reading, especially for lower level readers. It is available, for example, when using Eichousha's *Reading Skill Trainer* software, or *Rocket Reader* online.

Another type of help for enhancing online reading called, Visual-Syntactic Text Formatting (VSTF), has been tested by Walker, Schloss, Fletcher, Vogel and Walker (2007). This method transforms block-shaped text into cascading patterns to help readers identify grammatical structures. It has helped increase reading comprehension and the efficiency of reading online texts while reducing eye-strain among college readers. This VSTF method also helped increase high school students' academic achievement and long-term reading proficiency by more than a full standard deviation over randomized control groups in one academic year. This new method has been made feasible through computer-executed algorithms and electronic displays by integrating converging evidence from educational, visual, and cognitive research.

There do not seem to be many rigorous online studies yet of Web reading done by non-native speakers, using both speed and accuracy tracking, and also eye cameras to track and monitor perceptual movements such as regressions when reading online versus on paper. If such a comprehensive public grading system could be made available, it might indeed become a useful standard for both web-based and paper-based ER materials, but one must also recognize what a large project it would be, requiring the input of various educational bodies to achieve wider acceptance and use. In the meantime, traditional reading level tests that are online should be used and compared to see which provide the most helpful and consistent results for learners from various language backgrounds.

METHOD AND MATERIALS

Programs for Improving Vocabulary Accessibility with Online Glossing

Two major bilingual glossing programs — Rikai.com and Wordchamp.com (See Burston, 2007) — were used in a graduate reading course, alongside two online vocabulary level checkers. Rikai.com provides glosses from English to Chinese, Japanese, or Spanish, and can do auto-archiving of all target words looked up for later printing and review. Wordchamp.com will be explained in more detail below. The first vocabulary checker used was a simple, author-designed Vocabulary Knowledge Scale, known as the Dual Assessment Vocabulary Instructor-Evaluator (DAVIE). The second vocabulary checker used is called Vocab Check. In researching the use of these tools, three main research questions were identified:

1. Our primary and most basic research question was to find out: What is the relationship between using new types of Web 2.0 technology for CALL? Specifically, how can this more interactive, mobile World Wide Web of educational and social networks be used most effectively to produce the much-promised transformation of learning? In what ways

can Web 2.0 and 3.0 transform and improve language learning?

2. Secondary research questions applying this new technology to vocabulary, reading and language learning were: Do web 2.0 technologies contribute to the development of both intensive and extensive reading skills? If so, how? Why, or why not? Which online resources do EFL learners find most helpful in learning and using new English vocabulary and grammatical structures? Language educators and researchers need to ask: What are the implications and uses of web 2.0 for language education with reference to its innovative audio-visual, participatory and assistive technology? How can these new online technologies best be harnessed to increase language learning rates, proficiency and enjoyment? How can language teachers effectively guide students in the use of such online resources and socially interactive programs, in ways that are ethical, enjoyable and educational, so that their use does not degenerate into classes of online dating or worse?

Participants

Two groups of students were involved in this study. The first group consisted of a class of Japanese engineering students on a master's course (M = 38, F =1). The second consisted of two classes of English and Applied English Major students. Of the latter, one class had 15 students from the National Taiwan Normal University; the second class was from St. John's University and had 37 students. Thus, the total number of Chinese English students in this study was 52. The total of Japanese and Chinese in this study was 9, of whom 56 completed the English surveys summarized below.

Students taking the online reading course in Japan were Master's candidates in the new Department of Applied Science for Integrated Systems Engineering at a national university in Kyushu. Students' vocabulary and comprehension level and total estimated reading level were computed at the start of the semester course relative to American norms. A "Course Survey" and a "Website Evaluation" were also given at the end of this one-semester course. Average class reading levels for all 39 Japanese students relative to native reader norms in America (Loucky, 2003a) were assessed at the start of the fall semester: the average vocabulary level was grade 3.93, equivalent to the start of fourth grade level in the USA. The average reading comprehension level was 3.02, hindered by this low vocabulary level. The average expected reading grade level was the middle of third grade, or 3.51. Students wrote brief reports on each reading including a) a summary paragraph, b) impressions paragraph, c) five free comprehension questions and answers of their own, and d) constructed complete sentences for each new word they had listed. These were each printed or emailed, corrected by the teacher and returned for oral interviews.

DURATION AND DATA COLLECTION

Students had ten weeks from a fifteen-week one semester course in which to write at least five emails to Distant Learning Partners (DLPs) on their own outside of class, constructed around five general themes. They could choose words freely from pre-arranged Semantic Field Keyword (SFK) groups relevant to five academic disciplines, to help guide their writing. Each of these students was randomly assigned a keypal in the other country to write to online. Students had an average of two weeks for each email exchange, after which they were to print and submit it for credit. Partners could give each other peer-corrections, as well as making any corrections on their own after getting quick markups from teachers of where errors might exist in grammar, wording or usage. Students simply received credit for all email exchange letters handed in, and rough markups so they could make corrections and resend if they wished to do so. They were awarded a grade from 60-100% based on how well they completed email assignments in terms of their purpose, theme, and use of proper lexis and grammatical structures. Only printed versions were checked, though drafts could be written. Sending corrected versions to their partners was encouraged, but not checked or enforced.

Japanese students did all of their readings for this study online. In addition to online writings, blogs and use of a bilingual program, the Taiwanese students also used a writing text called *Steps to Writing Well* (Wyrick, 2005). Blogs did not work well enough to enhance these Chinese students' English this semester, so peer comments were encouraged and collected in addition.

ONLINE COLLABORATIVE WRITING PROCEDURES

Students were assigned five topics to write on, and told to use questions or statements for each of them, depending on their purpose and content. These five Collaborative Writing Exchange Topics Using the Semantic Field Keyword Approach (Loucky, 2004) within a Task-Based Language Teaching approach (Willis, 1996) were:

- **Topic 1:** Interview your new distance-learning partner (Using terms from Unit 1: Scientific Experimentation).
- **Topic 2:** Tell "My Life Story" (Using terms from Unit 2: History).
- **Topic 3:** Interview your new distance-learning partner (Using terms from Unit 3: Psychology).
- **Topic 4:** Tell your view of man, or how you think people and human civilizations came to be and where you think the world and humanity is going. (Using terms from Unit 4: Anthropology).
- **Topic 5:** Describe the culture and traditions of your people and country so a foreigner could better understand your nationality. (Using terms from Unit 5: Sociology).

These topics were first shared using the three phases of Willis' (1996) Task-Based Instructional Framework:

1. Pre-task Introduction
2. Task Cycle
3. Language Focus

For each of these five writing topics (different for each of five academic discipline areas and themes assigned), they were given 36 sets of Semantic Field Keyword groups of similar meaning-related words, but students could choose which of these they wanted to use and in what order. Their motivation was greatly heightened for writing in EFL since these were cross-cultural "Collaborative Writing Exchanges" between them as Japanese engineering graduate students and Taiwanese undergraduate English students. Data collection mainly consisted of recording students' averages for email exchanges done, pre-and post-test data for Japanese students on their knowledge of the first Unit of Semantic Field Keyword groups, and survey results for all who chose to complete English course surveys.

RESULTS

Pre- and Post-test class average scores for the Japanese graduate engineering students for Semantic Field Keyword Approach Unit 1-1 Sample provided interesting results. The pre-test raw scores were 22.86/60, equivalent to 37.92% organized correctly. Similarly, post-test raw scores were 33.73/60, or 56.11% organized correctly. The Learning Rate for Unit 1-1 was therefore 18.19%, a very good rate for a short-term study.

Taiwanese students did not use the LEARN Online Reading Lab program. Being higher-level English education majors, they both did some limited blogging and peer-correction of other written essays. Researchers only had direct control over the Japanese student's instructional material, but Taiwanese email exchange classes cooperated fully on five SFKA writing exchanges.

Survey of Online Reading and Collaborative Writing

On the "Survey of Online Reading and Writing Collaborative Course," 38 Japanese Graduate Engineering students and collaborating Taiwanese students completed an English survey and generally answered the questions very positively. 97 Japanese and Chinese participated in this study and 38/45 Japanese students completed surveys. However, just 18 Taiwanese students completed English surveys. The Survey Questions were as follows (*N=56*):

What have you learned from using the pre-organized, bilingual Semantic Field Keyword Approach online and doing Collaborative-Writing Exchanges using some of these words within assigned grammatical or topical frameworks?

Japanese Students' Answers: 13/37 or 35.14% were very positive. Chinese Students' Answers: 16/18 or 88.89% of answers were positive.

Which topic did you find the most difficult to write about? Why?

Various answers were articulated, for example:

Japanese Students' Answers: 1 each said the "Freed Hostage Trio" or the "Sake Story"; 4 said: "Kagawa's story because I didn't know him at all" (1 due to its difficult vocabulary); "Also his life was so busy it's hard to tell all that he did!" 2 said: "The first story in Japanese about Scientists." 2 said: "Manjiro/Neejima Joe." 3 said: "Pearl Harbor." 1 wrote: "(PH) Story, as I don't know about war"; 1 said: "PH as I didn't know those words. A third wrote: "Pearl Harbor, because the story is very long." 6 said: "SFKA Topics 4 & 5, Anthropology and Sociology — We don't think about it usually; I don't know much about my country to explain it to others." 2 said: "All SFKA Topics. All, since written in a language I don't know well."

Chinese Students' Answers: More than half wrote: Anthropology, "because the words and subject are complex or difficult (abstract)." Human civilization or Academic subjects, "since I am not professional in those fields"; "Because one's view of man is the most difficult topic, with many new words, so it took longer than others."

Do you think SFKA word lists improve your writing? Why or why not?

Japanese Students' Answers: 100% or 38 were positive. Chinese Students' Answers: A. 55.56% positive. B. 2 negative (5.25%). C. 33.33% or 6 gave no answer.

Do you think using the pre-organized, bilingual Semantic Field Keyword Approach online is a good way to help you increase your English vocabulary? Why or why not?

Japanese Students' Answers: A. 21/37 (56.76%) were positive. B. Negative: Only 1 (2.7%). C. Neutral/No opinion expressed: 15 (40.54%) gave no opinion.

Chinese Students' Answers: A. 11/18 (61.11%) positive. B. 1 Negative. C. 2 Undecided. D. 1 Recommendation given: One said: "It'll be better if SFKA could show us some example sentences." E. 2 (11.11%) Neutral/No opinion expressed.

Do you think our email exchange successful? Do you think your writing improved after this *exchange? State the reasons for your opinions clearly please.*

Japanese Students' Answers: A. 22 (57.89%) positive. B. 8 (21.05%) negative. Including 1: "No, because I couldn't get emails." 1: "No, since words or topics were limited." 1: "No because one sent me none, the other's English was too difficult for me." C. 1 Neutral said: "Not sure if successful, but it improved our English!"

Chinese Students' Answers: 7/18 (38.89%) of Taiwanese said: A. "Yes, it's a good way." B. 5/18 (27.78%) gave "No" answers. C. One (5.56%) gave it a 50% rating. Reason: "Because our keypal was Japanese … If the nationality could be European [with higher language proficiency many others wrote] that'll be better."

If you took the V-Check or used the WordChamp.com website to test your vocabulary level online, did it help you? If so, please tell your impression or opinion about how it was helpful or motivating to you. (Japanese students used both V-Check and the WordChamp.com website. Chinese only used V-Check).

Japanese Students' Answers about V-Check: 14 (36.84%) were positive, 2 mixed, the rest (58%) gave no specific response to this question. However, when ranking websites used in class for the usefulness, 24/38 (63%) of them chose WordChamp.com as their first or second favorite site.

Japanese Students' Answers about WordChamp.com: A. 18 Positive (47.4%). B. 2 Negative, "No, it was too slow on our LAN."

Chinese Students' Answers about V-Check: 8/18 (44.44%) were positive. Five wrote mixed opinions, with complaints or suggestions to improve V-Check.

Did you gain any new ideas or strategies for improving your English vocabulary, reading or writing strategies and skills? Yes or No. If Yes, please tell which particular skills and strategies did you learn that you will use the most or may help you most practically in the future?

Japanese Students' Answers: Six (16%) said: "yes." 4 wrote: "Reading in English improved. I will study English harder!" Two said: "Especially I gained Vocabulary skills; I gained practice in writing English sentences!"

Chinese Students Answers: Half (9/18) were positive.

If you took the V-Check to test your vocabulary level online, what was your impression or opinion about it? Was it helpful to you? Motivating?

Japanese students were given a survey about their online reading practices and learning, shown above. Chinese students instead were asked: *What do you feel about peer-commenting? Did you benefit from your classmate's comments? Why or why not?* Taiwanese students used and appreciated the ability to develop their English by doing blogging and peer-correction online.

Japanese students' responses to a mini-survey on websites and reading methods used in class and two scientists studied using them will be summarized here, called Question 9 on their survey.

Rank 1-5 which of these Websites "Most helped you to improve your English skills." Also "Put a check" on the right of any Website that you used if it helped you to learn new English vocabulary, reading/writing skills and strategies online (Rank#, then # of Students). Rank 1-5; Circle with "O" if this Website helped you to improve.

A. (www.call4all.us) #1-18; #2-7; #3-4; #4-2; #5-1; #7-1.

O. 26/38 students said this website helped them to improve their English. Numbers show how they ranked each site.

B. (www.WordChamp.com) #1-10; #2-14; #3-2; #4-5; #5-2. O-25/38 "Helped my English".

C. (www.Rikai.com) #1-6; #2-10; #3-13; #4-1; #5-3; #6-1; #7-1. O-26/38 “Helped”.
D. Online Dictionaries — CALL4ALL’s Dictionary page, or which online dictionary did you use most? #1-2; #2-8; #3-7; #4-11; #5-3 #6-1. O-18/38 “Helped my English.”
E. (www.learn.com Site) #1-2; #2-3; #3-5; #4-6; #5-10. O-19/38 “Helped.” 1-X “Did not help.”
F. Online Reading Labs (assembled at R-Reading Page of CALL4ALL.us). #1-2; #2-5; #3-6; #4-3; #5-6; #6-5. O-17/38 “Helped my English.”
G. OTHER English-Japanese Web Dictionaries Used: 4 Listed. 2 used ALC (SPACE); 1 Sanseido.net; 1 MSN Encarta Dictionary.

To summarize the above ranking of websites used, one can see that Loucky’s course website was the most highly favored, with 68.42% (26/38) saying it “Helped me improve my English,” and 47.37% (18/38 students) choosing it as their #1; 7 students as their #2; 4 students as their #3; 2 students as their #4; 1 student respectively as his #5; or #7 choice. WordChamp.com, found helpful by 65.79% of these students (25/38), was second in popularity, with 10 students choosing it as their first choice, 14 as their second, and 9 others choosing it as their third to fifth choices. Third in popularity was Rikai.com, found helpful also by 68.42% (26/38 learners), and chosen as their top by 6. It was second choice for 10, and third choice for 13 learners, with another 6 ranking it #4-7 among their choices. 32 students viewed CALL4ALL’s Dictionary page as being helpful to them (84.21% using it) 17 ranking it in their top 3 choices. Fifteen others placed it in their top fourth to sixth choices. When asked, “Which online dictionary did you use most?”, only these other online dictionaries were listed, all of which are included on CALL4ALL’s Dictionary page as well: 4 listed ALC (SPACE); 1 Sanseido.net; and 1 MSN Encarta Dictionary. Finally, Japanese student responses to the mini-survey on reading methods and scientists will be summarized here. Asked on their final Reading Survey section:

Which way of reading did you prefer?

92.10% (35/38) chose: a) reading online with bilingual glossing support, vs. only 7.89% or 3/38 chose: b) reading printed handouts or textbook articles?

An overwhelming majority (92.1%) prefer having bilingual glossing support for their online readings. Teachers and E-Learning developers should always keep this in mind.

Which way of reading was easier for you to learn the meaning of new words?

65.79% or 25/38 chose: a) When reading online with bilingual glossing support, or 28.95% or 11/38 chose: b) when reading printed handouts or textbook articles? So approximately 66% said it was easier for them to learn new words having such bilingual glossing.

Do you think you learned how to use strategies for reading more effectively?

32 chose: a) When reading online with bilingual glossing support, or 3 chose: b) When reading printed handouts or textbook articles?

84.21% state they learn to use a larger number of reading strategies more effectively when reading online with such bilingual support.

When reading about scientists using the LEARN Website, which way did you read?

A. Einstein Story: 9 read only and 14 read and listened to it
B. Edison Story: 8 read only and 16 read and listened to it

Which way of reading did you prefer doing in this class?

A. Online Reading without Listening support: 4 (10.53%)
B. Online Reading with Listening support: 31 (81.58%)
C. Offline Reading of printed texts only: 3 (7.89%)

Again it was clear that about 82% of these learners prefer reading online with listening support. This is a significant finding with potentially far reaching implications for CALL and Extensive Reading to analyze.

Based on your reading, who do you think was smarter?

7 answered a) Einstein and 8 b) Edison as opposed to c) with 23 and "both the same." Only 1 answered d) another scientist.

Why do you think so? Please give your specific reasons for your opinion here.

23 said "Both." Example answers included: "Both were great, so I can't decide." "Because I think all scientists are great." "These two are too smart to compare!" "Both were geniuses." "Both, because everyone knows both." "Both contributed to the world's development." A number said, "I respect both. They are not comparable, since Einstein theorized, but Edison manufactured." "Both are great scientists, both very smart." "We can't compare them." 7 chose Einstein, one saying, "Einstein, since his IQ score was 300!" 8 chose Edison, one saying "because he not only invented new products, but also a system to earn money!" "I like Edison … most popular inventor for our lives."

When designing language learning websites three major parameters of subjective enjoyment and objective effectiveness as well as technological efficiency should all be considered. In order to do so, students' improvement during this one semester course was assessed by two measures: a) average performance and participation in written reports and twelve online articles, and b) overall performance during three sessions using the Online Reading Lab articles. Their performance when reading these articles was assessed in three ways: 1) by the average number of stories read, 2) by their average speed when doing these timed readings, and 3) their average percentage of comprehension for all stories read during each session.

A majority of students reported that using the teacher's website (www. CALL4all.us) made the course very enjoyable and efficient for them. Students always did the reports unless absent, often making up written reports with much diligence, resulting in an overall class average of 76.75% on these homework reports, which were graded based on their grammatical accuracy, completeness of reporting and word study indicated. Objective test results — 59% average online comprehension despite this EFL class averaging just 3.5 in their total reading grade level — also showed a good level of improvement in learners' average vocabulary and grammar use levels, clearly supporting the effectiveness of such a blended online course. Thirty-five students completed an average of 18 online readings in a mean time of 6.78 minutes per reading. Since these readings were designed to be read in just five minutes, it became apparent that these graduate engineering students need more work on learning the essential core vocabulary required to read at a higher level with greater speed.

These were Japanese average comprehension scores for all readings done using Balsamo's Online Reading Lab on each of three days, as well as students' total overall average. As one would expect, from an initial average score of 54.19%, their comprehension scores increased to 63% and 60.5% on two subsequent days. Each time they were encouraged to try to read ten online articles on topics in areas of their choice. Students' total overall "Online Reading Averages" when doing timed online extensive readings on topics of their choice were as follows: 1) Average Comprehension, for Day 1: 54.19; 2) Average Comprehension, for Day 2: 63; and 3) Average Comprehension, for Day 3: 60.5. The Total Average Comprehension was 59.39% over three days using this online reading lab.

In sum, both objective and subjective assessments showed that a large majority of these students improved markedly, and enjoyed this course, which blended assigned online readings with integrated four skills English language development activities (written reports and paired interviews based on online readings) as described above. The course was not long enough (just one semester) to measure reading gains by grade level.

Students wrote brief reports on each online reading including: a) a summary paragraph, b) impressions paragraph, c) 5 free comprehension questions and answers of their own, and d) constructed complete sentences for each new word they had listed. These were each printed or emailed, corrected by the teacher and returned for oral interviews, emphasizing oral and written correction of grammar errors. All reports received a grade as they accounted for 80% of the semester grade. Consequently, assignments were taken seriously and done regularly by almost all students. Final class average for ten of these reports required was 78%, a figure close to Japan's A level for 80% and above.

This five-month semester course emphasized developing online reading skills using bilingual glosses and regular, blended and balanced integration of CALL with all four communication skill areas as described above. It was necessary to try to balance an intensive reading approach to cover higher level technical articles assigned by other engineering teachers, with an extensive approach using an online reading lab. The students' general surveys (*N=38*) showed an appreciation for both approaches, and improvement in their speed and comprehension during second and third sessions using the online reading lab as follows. Using Balsamo's Online Reading Lab, they averaged reading 18 stories over three weeks, at an average speed of 6.78 minutes. While average comprehension scores were close to just half (54.18) during the first week, they improved to 63 and 60.5% during weeks 2-3.

DISCUSSION

We have been able to develop a multi-purpose language learning site including an Online Reading Lab (ORL) and succeeded in fully integrating practice in all four communication skills with it for a graduate level course. Since the learners' average vocabulary level (grade 4.0) was comparable to that of undergraduate freshmen engineering students at the same national engineering university in Kyushu, Japan, such a course using only the Online Reading Lab's easier articles could be more successful in the future.

Technical articles would be skipped and simpler Rikai.com articles used instead, especially ones having instant online bilingual glossing available. The following resources and services were provided by this course and website:

1. Interesting, authentic online reading materials (copyright free).
2. Comprehensible input facilitated by instant bilingual glossing and other web dictionaries.
3. Comprehension questions on each article were available for each timed, online Reading Lab article. Learners wrote their own questions and answers for online articles, chosen and assigned by ten other engineering professors, to enhance and ensure their mental and linguistic interaction with each text. These were followed up with

oral/aural practice using these same questions after being checked for grammatical accuracy by the teacher.

4. Feedback was given by writing brief summaries, impressions and comprehension questions for each of these 10-12 academic articles.

The high levels of learner enjoyment and clear effectiveness of this type of CALL-based ESP online reading course suggests that many more courses should strive to have a web presence, especially reading and writing courses. This study also showed the benefits of giving end-user surveys and interviews, as well as objective post-tests and ongoing monitoring and assessment of students' learning, in order to improve such courses with added feedback. This online ESP course blended with interactive, communicative language learning activities both in-class and out also revealed that making parts of an online reading course available at all times on the Web and demonstrating it in class can ensure that students do use it effectively. Not only do language learners use such a website when it is intentionally and effectively integrated into regular class use, but they also seem to greatly enjoy and benefit from using it, as reported on their course surveys averaged by the school, and demonstrated in their online reading reports.

These were the results for assessing just the first article on hurricanes from Balsamo's online Reading Lab:

1. In less than 2 seconds, so much linguistic and lexical data can be generated for any text such as this, either inputted from any online text, text file or scanned text that one must summarize only the word data types, as it generated seven pages of data. They included this information about word families, types, tokens and percentages; a color-coded text showing word bands clearly with different colors. In addition, Token Lists for various Word Bands were all printed out. The AWL File produced at level 10: for Hurricances and Tornadoes article showed these academic words in bold print: similar, temporary, area, normally, predicted, ignored, considerably, normal, enormous, encounter, and capable. In this program each level includes all the previous levels, so band 10 includes 1-10. By providing such color-coding and word frequency bands, teachers can help students to focus on how to study the words they most need to learn in communicative and effective ways.
2. AWL only highlights ten levels of academic words within similar bands by bolding them. This is very helpful for quickly focusing both teachers' and learner's attention on essential vocabulary for understanding that text, for example here shown for the first Academic Word List level. This program will identify core academic vocabulary in a text, using the Academic Word List. It does look easier to print and much more manageable for teachers and students who are not linguists than the Vocab Profiler, whose advantage is its ability to assess both easier General Service List (GSL) words, as well as AWL words, focusing learners' attention on words above their present level.

English Vocabulary Profilers

Other linguistic data important to note and summarize here are these facts, which can be edited from an excellent function provided by Cobb's Vocab Profiler site called "Edit/print-friendly table." It is important to note that while our Target Story was reported to have only about 3% (2.68%) AWL words, 15.05% of the text are off-list words, which must be known to comprehend the story or read it fluently with adequate understanding. Since no more than 1 in 20 running words or 5% should ideally be unknown even for native readers (Ekwall, 1976), encountering these close to 18% yet unknown AWL and Off-List Words would make even this short article incomprehensible or frustrating for a majority of Japanese college students. Most undergraduates possess an average of only about 2,500 words, with graduates averaging about 3,500 known words, among thousands of learners studied repeatedly at seven colleges over ten years (Loucky, 1996; 1997; 2003a; 2003b).

Alternatively, one may use the AWL Highlighter to work on vocabulary found in the Academic Word List, but this has only 570 words (Coxhead, 2000). Thus off-list words needed by students would not be covered here, making the Vocab Profiler a much more versatile instrument, especially once learners have mastered these AWL terms. As an example, when inputting our target Pearl Harbor Story text into it, CAVE allows one to choose which of the AWL Sub-lists to scan for. At the highest level 10, these 35 words were highlighted (and at times repeated) in bold type by this vocabulary search engine: intelligence (information), objective (aim), military (adjective form), preliminary, accurately, plus, exploit, primary, principal, intervention, converts, ignore(d), encounter, assistance, conference, distributing, published, involved, committed, eventually, volunteered, found, finally, eventually, relevant, dynamic, attitude, liberated, motivation, seeking, purchase, despite, traditionally, drama, substitute. The advantages of using CAVE first are that it is more narrowly focused just on helping one to identify AWL terms needed by sub-lists, without distracting users by any other linguistic data, many of whom would be overwhelmed by Vocab Profiler's excessive data.

3. **Flesch Reading Ease:** First a percentage of passive sentences is shown as 36%. Then a reading ease score of 54.1 out of 100 is given.
4. **Flesch-Kincaid Grade Level:** Finally, the most important reading level perhaps for teachers to know and pay attention to when assigning online reading tasks is this, since it determines a text's estimated grade level of difficulty. The Hurricane text was assessed as being at a grade 10.2 (2nd month), so that students at a level of more than 6 months to a year lower than that should not be asked to read such texts for free reading. Generally speaking, such texts could be used for instructional reading for students reading at 1-2 levels below that, from about grade 8-9 level. Students reading at less than that level would tend to become frustrated with such texts, mainly due to their not knowing over 5%, or 1/20 running words. Two conditions could reduce their learning burden, to enable learners reading at lower grade (such as grade levels 5-7) to endure such texts without undue frustration: a) allowing and instructing them to use online or portable bilingual/bilingualized dictionaries, or b) if they have a very strong interest and background knowledge in the field of a particular text. Otherwise avoid the frustration level. Other lexical and linguistic data displayed at the same time by this program for this reading text for example were these facts. This text had 565 words, 9 paragraphs, 30 sentences; averaging 5 per paragraph, 18.4 words per sentence, with 4.6 characters per word.

Interestingly, reading pacers differ. The one used at Balsamo's online Reading Lab is basically a five-minute countdown speed-reading stimulator. Robb's (2008) reading lab site provides another timing device, which ideally should be part of all online reading or language learning labs. It measures total time on task. Learners and teachers can thereby get clear measurements of either free-reading or study times. Adding adjustable pacers and levels of text difficulty to all Web pages intended for E-Learning — along with a choice of either bilingual, monolingual glosses or both, as well as instant Text-to-Speech services — would be even more ideal, especially for lower level language learners. Adding listening support should be done wherever possible for language learners, since Extensive Reading alone is known to be too slow to allow more than incremental vocabulary development to occur (Rory, 2005). These options are already all available through references and links integrated at the CALL4ALL website (Loucky, 2008), which serves as a free Web 2.0 Virtual Language Education Library of various websites and applications useful for learning or teaching 120 languages.

CONCLUSION

More innovative Web 2.0 technology enables us to manage increasing amounts of semantically rich metadata and to deliver software and services for information management to users from most language backgrounds worldwide. There is a clear drive towards connectivity happening globally today, so that almost anyone with access to a computer can connect with millions of people around the world to collaboratively create, share and consume all forms of digital content at virtually no cost. Using Web 2.0 educators can now manipulate and share enormous quantities of data, so that people all over the world can more easily connect, talk to one another and exchange ideas, provided of course that they can overcome linguistic, cultural and vocabulary barriers.

Due to the potential for sophisticated mass collaboration that this technology wave provides, people are now able to make almost unlimited connections across the planet. However, often a majority of users are not English native speakers or readers, so they require many more means of support to enhance comprehensibility. Clearly such text analyzers, summarizers, glossing and translation engines to simplify text, as well as multimedia and TTS listening support options have great relevance to the needs of many users of Web 2.0, whether it be for online language learning, social collaboration, rating or tagging shared content, collaborative filtering of news, blogs, or other recommended content or to help improve the comprehensibility of any other shared Web browsers, program applications, components or recombinations.

In summary, one may assess vocabulary and reading levels not only for print but online for text from any of these Web components in the following ways, the first three of which are free and described by Loucky (2008) with links from the Reading and Readability page. Enter any text at any of these three programs to find out its reading level:

1. AWL URL: (http://www.nottingham.ac.uk/~alzsh3/acvocab/awlhighlighter.htm).
2. Vocab Profiler URL: (http://www.lextutor.ca/vp/eng/).
3. Word Spelling/Grammar Checker (explained in Office 2007 Word Help).

When Microsoft Office Outlook and Microsoft Office Word finish checking the spelling and grammar, you can choose to display information about the reading level of the document, including readability scores according to the following two tests: a) Flesch Reading Ease, and b) Flesch-Kincaid Grade Level.

Alternatively, enter any book title and or its ISBN to find out its grade level:

1. By using TASA's Depth of Reading Power, on a scale of 1-100.
2. By Reading Renaissance's ATOS, by school grade levels (relative to U.S. norms).

Loucky (2008) has been able to develop a multi-purpose language learning site, including several Online Reading Labs (ORLs) and succeeded in fully integrating practice in all four communication skills using it with graduate level Japanese engineering students. Since the learners' average vocabulary level (grade 4.0) was comparable to that of undergraduate freshmen engineering students at the same national engineering university in Kyushu, Japan, such a course using only the Online Reading Lab's easier articles could be more successful in the future. Technical articles would be simplified, by having the *WebReader* instant online bilingual glossing feature (www.WordChamp.com) made available for them, along with TTS listening support.

The following resources and services were provided by Loucky's (2008) online course and website:

1. Interesting, authentic online reading materials (copyright free).
2. Comprehensible input, facilitated by instant bilingual glossing and other web dictionaries.
3. Comprehension questions on each article were available for each timed, online Reading Lab article. Learners wrote their own questions and answers for ETP articles, chosen and assigned by ten other engineering professors, to enhance and ensure their mental and linguistic interaction with each text. These were followed up with oral/aural practice using these same questions after being checked for grammatical accuracy by the teacher.
4. Feedback was offline and done personally with the teacher, orally or in writing brief summaries, impressions and comprehension questions for each of these 12 academic articles.

The high levels of learner enjoyment and clear effectiveness of this type of CALL-based ESP online reading course suggested that many more courses should strive to have a web presence, especially reading and writing courses. This study also shows the benefits of giving end-user surveys and interviews, as well as objective post-tests and ongoing monitoring and assessment of students' learning, in order to improve such courses with such added feedback. This online ESP course blended with interactive, communicative language learning activities both in-class and out has certainly shown that making parts of an online reading course available at all times on the Web and demonstrating it in class can ensure that students do use it effectively. Not only do language learners use such a website when it is intentionally and effectively integrated into regular class use, but they also seem to greatly enjoy and benefit from using it, as they reported on their course surveys and demonstrated by high homework averages (78%).

Pedagogical Implications and Recommendations for Web 2.0 Reading Programs

Recent proposals for a standardized grading scheme for web-based reading materials are timely and welcome. This overview has shown how online reading lab stories and articles linked to Loucky's (2008) site can be easily copied and pasted into Cobb's Vocab Profiler for quick reading level analysis. The text of any scanned story or webpage can be analyzed in the same way, giving results that are extremely helpful to teacher, researcher or students in terms of word levels or frequency bands. Others such as McGovern's EFL Reading site report using a rudimentary scheme combining the readability statistics available with Word (Flesch Reading Ease, Flesch Kincaid Grade Level) with his own personal judgment based on experience as a teacher and writer.

Besides using these two Word readability formulas, both Cobb's Vocab Profiler and the AWL (using CAVE formula) site were used to assess basic reading level of articles from Balsamo's online reading lab. Links to each of these are included at the author's website, under L. Language Learning and Reading Labs Online. Teachers, learners or web writers should learn to use these. These were the results for assessing just the first article on "Hurricanes" from Balsamo's online Reading Lab: 1) in less than 2 seconds, so much linguistic and lexical data can be generated for any text such as this, either inputted from any online text, text file or scanned text that one must summarize only the word data types, as it generated several pages of data. They included this information about word families, types, tokens and percentages; plus a color-coded text showing word frequency bands clearly.

Two conditions could help *reduce the cognitive load or learning burden* of more difficult texts, online or in print, to enable learners reading at lower grade (such as grade levels 5-7) to endure such texts without undue frustration: a) allowing and instructing them to use online or portable bilingual/bilingualized dictionaries, or b) if they have a very strong interest and background knowledge in the field of a particular text. Otherwise we should always avoid frustration level materials, and employ reading materials at appropriate independent levels for free/extensive reading outside of class, or at instructional levels (generally not more than ½-1 year beyond independent levels) for content or classroom learning.

Conclusions Considering Cultural Aspects of Technology Usage

In regard to our Research Questions we have shown various ways new types of Web 2.0 technology can be employed to enhance CALL. First this needs to be done by making online reading more accessible to readers of all language backgrounds by adding instant access glossing (both bilingual and monolingual) and translation engines to all sites, along with listening support and summarization tools. Secondly, we have suggested some ways that interactive, mobile educational and social networks can be used to more effectively and enjoyably bring about the transformation and improvement of language learning promised by Web 2.0 and 3.0 technologies. Finally, we have demonstrated at our large Virtual Language Education site how to more fully integrate and apply this new technology to enhance vocabulary, reading and language learning. Naturally, Web 2.0 technologies can be used in the many ways shown by Loucky (2008), to contribute to the development of both intensive and extensive reading, and all four communication skills in any language available online.

In previous studies Loucky (2008) found Engineering students in Japan were generally more open to the use of technology and more adept at using electronic dictionaries effectively than typical humanities students of English in Japan, including English majors (Loucky, 2003b). No distinctions between male and female participants were found, although few females tend to major in Engineering in Japan. What relationship could we find between Chinese and Japanese students and their English language learning in this study? What common problems do they have with reading or writing in English? How can technology enhance reading strategies in Asian contexts, such as Japan and Taiwan, where our collaborative writing exchanges were done? These students do seem to be more open to using technology in the classroom than other students because of their society's normalization of technology, and due to having higher computer and English literacy than average Japanese lower level learners.

Using such digital devices as e-readers and mobile phones with Internet connectivity can enable students to gain better access to reading materials in the classroom or for mobile online learning. Such Web 2.0 and emerging Web 3.0 technology promises to revolutionize reading, especially as language learning becomes more mobile/portable, user-generated and –controlled. Language learning sites that enable users to download content directly to their portable or desktop devices should enhance out of class, independent language learning and use. So far, though, Japanese students' use of mobile phones for reading and vocabulary learning has been too expensive, slow or hard to keep on task (Loucky, 2003c). iPods could greatly enhance extensive reading with listening support if text and sound files could be easily downloaded simultaneously by users at different speeds and levels of text difficulty (as our students experimented with using the learn.com site). In Japan, for example, the DoCoMo cell phone service already offers downloadable novels and Manga to mobile phones.

Among the aspects of online learning course design to take into consideration in future online course development are these:

1. How to ensure that the website's purposes and learning objectives are clear to both students and teachers using them.
2. What are implications for learners' workload (how can blended in-class use help increase actual communication, learning and motivation while decreasing time they must spend working alone).
3. What are implications for teachers' workloads? (How can CALL help to decrease teachers' "take-home work," or enable them to even communicate or give feedback from home or office between infrequent classes?).
4. How can we ensure that end-users' online learning experiences are "of a seamless whole that incorporates all aspects of the online experience (conferencing, library, student and tutor homepage, etc.)" (Shield & Kukulska-Hume, 2004, p. 32), and better blend these together with other aspects of in-class or take-home integrated four-skills communicative language learning?

This study and website suggest initial answers to these questions, and could serve as a useful model for EAP/ESP/ETP online courses, as well as for blended reading courses to consider. It helps to advance an integrated model of how language learning websites can be better designed for blended in-class and mobile use, so that more enjoyable and effective language learning can take place, helping students to improve their vocabulary and reading skills online, as well as other communication skills interactively, face-to-face off-line.

KEY TERMS

Degrees of Reading Power (DRP): Touchtone Applied Science Associates' (TASA) Depth of Reading Power (DRP) program. TASA Literacy Online uses a scale of 0-100 in their measure of text and student reading level. They call these levels Degrees of Reading Power (DRP). Primary and Standard DRP tests assess learners' ability to comprehend surface meaning of prose, whereas Advanced tests assess the inferential and global reading skills of more proficient readers. DRP technology relies on the close link between text difficulty or readability level and comprehension test results. As such, they can be interpreted as criterion-referenced tests, indicating what a particular student can actually do.

Degrees of Word Meaning (DWM): TASA has designed and used tests of vocabulary in context called Degrees of Word Meaning (DWM). This vocabulary level testing scheme provides a brief Conversion Table, which helps teachers convert these DWM vocabulary level scores into an estimated size of students' reading vocabularies. Degrees of Word Meaning scores range from 850 (the equivalent to knowing over 157,000 words), to less than 300 (indicating that such a test taker knows 100 or fewer English words). Their products for educational assessment are include tests as well as online programs and steps for estimating both reading levels and readability of any text or book.

Digital Rights Management (DDR): An umbrella term that refers to access control technologies used by publishers and copyright holders to limit usage of digital media or devices. It may also refer to restrictions associated with specific instances of digital works or devices. DRM overlaps with software copy protection to some extent, however the term DRM is usually applied to creative media (music, films, etc.) whereas the term "copy protection" tends to refer to copy protection mechanisms in computer software.

Extensive Reading: This approach to reading is used when encouraging students to read widely, especially outside of class, at their Independent or Free Reading Level. Extensive reading is also known as pleasure reading, since its purpose is free, independent reading that is not overly dependent upon either teacher or dictionary.

Frustration Level: Learner recognizes less than 90% of running text. Comprehends under 50% of text. Such texts should either be totally avoided, unless working online with bilingual glossing available. Ideally language learners should also have fully bilingualized lexicons, concordancer and listening support available for any texts at less than Independent Level.

Intensive Reading: This approach to reading is used when intentionally teaching and practicing reading skills in classes or doing assignments out of class that require reading at one's Instructional Level, which may be from ½ to 2 years above free or Independent Level.

Independent Reading Level: Learners recognize 98-100% of words in text. Comprehend at better than 90%, so they can read such texts freely on their own.

Instructional Reading Level: Learners recognize 95-97% of words in text. Comprehends ideally at least 75%.

Online Language-Supported Manageable Text (OLSM Text): This refers to text not yet at a language learner's Independent Level, but made manageable via online tools such as fully bilingualized lexicons, concordancer and listening support. Levels might range as follows: learners may recognize 90-95% of words in such texts and comprehend ideally at about 75-89%, although with harder texts comprehension levels may fall between 51-74%.

Readability: Readability is an assessment of how easy a text is to understand for a given population. Online text readability includes four distinct constructs: 1) the reading ability or level of the user, 2) the readability level of a text, 3) its vocabulary level, and finally 4) readability assessment tests, instrument scales or indices themselves.

Chapter 5.14
Querying Web Accessibility Knowledge from Web Graphs

Rui Lopes
LaSIGE, University of Lisbon, Portugal

Luís Carriço
LaSIGE, University of Lisbon, Portugal

ABSTRACT

Web Accessibility is a hot topic today. Striving for social inclusion has resulted in the requirement of providing accessible content to all users. However, since each user is unique, and the Web evolves in a decentralized way, little or none is known about the shape of the Web's accessibility on its own at a large scale, as well as from the point-of-view of each user. In this chapter the authors present the Web Accessibility Knowledge Framework as the foundation for specifying the relevant information about the accessibility of a Web page. This framework leverages Semantic Web technologies, side by side with audience modeling and accessibility metrics, as a way to study the Web as an entity with unique accessibility properties dependent from each user's point of view. Through this framework, the authors envision a set of queries that can help harnessing and inferring this kind of knowledge from Web graphs.

INTRODUCTION

Since its inception, the Web has become more and more prolific in people's lives. It is used as an information source, both one-way (e.g., newspapers) and two-way (e.g., blogging, forums, or even instant messaging). New Web sites and new content are produced and published each second by both professionals and amateurs, each one with different usability and accessibility quality marks. This fact, in conjunction with the Web's decentralized, yet highly connected architecture, puts challenges on the user experience when interacting and navigating between Web sites.

At the same time, the attractiveness of the Web brings more users to use it on a regular basis. This means that user diversity will be closer to real life where both unimpaired and impaired users coexist. Since each user has its own specific requirements, (dis)abilities, and preferences, their experience is different for each one, resulting in different satisfaction levels. In the same line of user diversity, device prolificacy and Internet connection ubiquity also contribute to the range of possible user experiences on interacting with the Web and, consequently, also have a stake in accessibility issues.

For all these reasons, the shape of the Web itself deeply influences each user's interactive experience in different ways. Users tend to navigate through the Web by avoiding Web sites that cannot be rendered correctly, which provide poor interactive capabilities for the specificities of the user or the device she/he is using to access the Web, reflecting negatively on users' experience. Therefore, it is required to understand the Web's graph of Web pages at a large scale from the point-of-view of each individual's requirements, constraints and preferences, and grasp this information to devise future advancements on Web standards and accessibility-related best practices. The inability to adapt the Web, its standards, technologies, and best practices will pose severe problems on the society in general, by leaving untouched the barriers towards a proper e-inclusion level that can actually cope with everyone, independently of impairments and related needs.

The main contributions of this Chapter are: (1) the establishment of a Web accessibility framework that can be used to create complex knowledge bases of large scale accessibility assessments; and (2) a set of query patterns to infer critical aspects of the accessibility of Web graphs with a fine-grained control (based on users' requirements and constraints). The proposed framework and the set of query patterns will form a core tool that helps analyzing the semantics of the accessibility of Web graphs. Next, we describe the relevant background work on Web accessibility and knowledge extraction from Web graphs.

BACKGROUND

Two main research topics have influence and contribute to the study of Web accessibility on large scale: the analysis of accessibility compliance of a Web page (or Web site), and the analysis of the Web's graph structure.

The Web Accessibility Initiative (WAI, n.d.) of the World Wide Web Consortium (W3C, n.d.) has strived for setting up the pace of Web Accessibility guidelines and standards, as a way to increase accessibility awareness to Web developers, designers, and usability experts.

The main forces of WAI are the Web Content Accessibility Guidelines, WCAG (Chisholm et al., 1999). WCAG defines a set of checkpoints to verify Web pages for specific issues that have impact on accessibility of contents, such as finding if images have equivalent textual captions. These guidelines have been updated to their second version (Caldwell et al., 2008) to better handle the automation of accessibility assessment procedures, thus dismissing the requirement of manual verification of checkpoint compliance.

Until recently, the results of accessibility assessment were presented in a human-readable format (i.e., Web page). While this is useful for developers and designers in general, this is of limited use for comparison and exchange of assessment results. Therefore, WAI has defined EARL, Evaluation and Report Language (Abou-Zahra, 2007), a standardized way to express evaluation results, including Web accessibility evaluations, in an OWL-based format (Dean & Schreiber, 2004).

EARL affords the full description of Web accessibility assessment scenarios, including the specification of *who* (or *what*) is performing the evaluation, the *resource* that is being evaluated, the *result*, and the *criteria* used in the evaluation.

However, EARL does not provide constructs to support the scenarios envisioned in macro scale Web accessibility assessments. It cannot cope with metrics (thus dismissing quantification of Web accessibility) and with the Web's graph structure. This way, EARL becomes limited to single Web page qualitative evaluations.

Lopes & Carriço (2008a) have shown that current Web accessibility practices are insufficient to cope with the whole spectrum of audiences (both disabled and unimpaired users), and that any user can influence everyone's interactive experience on the Web (especially regarding accessibility issues). As Kelly et al. (2007) have predicted, to cope with every user, holistic approaches to Web accessibility have to be taken into account. This includes tailoring of accessibility assessment procedures to each individual's characteristics, as thoroughly discussed by Vigo et al. (2007b).

Generalizing the concept of accessibility to all users (and not just to those that deeply depend on it – i.e., people with disabilities), the adequacy of user interfaces to each user's requirements, limitations, and preferences is the ultimate goal of *Universal Usability*, as defined by Shneiderman (2000). As detailed by Obrenovic et al. (2007), one has to take into account users, devices, and environmental settings when studying accessibility in a universal way. However, to our knowledge, there is no work on how to measure the universal usability quality of a single Web page, from the perspective of a unique user (*per definition* of universal usability).

When scaling up to the size of the Web, other aspects of analysis have to be taken into account. The characterization of the Web (e.g., its size, analysis metrics, statistics, etc.) is a hot topic today. *Web Science* is emerging as a discipline that studies the Web as a dynamic entity, as described by Berners-Lee et al. (2006). It is centered on how infrastructural requirements, application needs, and social interactions depend and feed each other in the Web ecology (Hendler et al., 2008).

At a more fundamental level, one of the core aspects of studying the Web concerns on how it is universally usable, as hypothesized and defended by Shneiderman (2007). However, since this discipline is fairly new, little is know about the Web from a universal usability point-of-view. It is known that the evolution of Web standards has influence on the way users navigate and interact with the Web (Weinreich et al., 2006), but not to what extent and what is the impact on each individual's characteristics. By having a proper characterization of the Web's graph from each individual's point of view (i.e., requirements, needs, constraints, preferences), more complex studies can be preformed at higher abstraction levels, such as in-depth Social Network Analysis (cf. Berger-Wolf & Saia, 2006) and other types of social studies.

In Lopes & Carriço (2008b) the authors presented a mathematical model to study universal usability on the Web. It supports the analysis of the Web from the point-of-view of each user's characteristics, and explains how the Web's structure influences user experience. While the authors have hypothesized how this model can be used to observe the evolution of the Web, it just provides a theoretical framework for the analysis of accessibility. Nevertheless, this model provides interesting contributions on how the query patterns presented in this Chapter should be formulated.

WEB ACCESSIBILITY KNOWLEDGE FRAMEWORK

In order to open the way to querying different Web accessibility properties from Web graphs, we have defined a supportive knowledge framework. This framework groups four different components, as depicted in Figure 1: *Web Graphs*, *Web Accessibility Assessment*, *Audiences*, and *Metrics*. The framework has been design according to the following requirements:

- *Universal*. The framework should not be limited to "traditional" accessibility audiences (such as people with visual impairments), but cope with different kinds of accessibility-prone issues, such as limited interaction devices (e.g., mobile phones), or adversary environment settings (e.g., poor lighting settings). The universality concept can (and, in fact, should) be also extended to all users and usage situations, thus allowing knowing the impact of Web accessibility and similar universal usability issues on any user.

- *Generalized*. The framework must not impose *a priori* any limitation or bias towards particular accessibility assessment concepts. It should define them at a meta-level, in order to be possible to define query patterns that are independent from particular instances (e.g., a query pattern depends on user characteristics, not on *a* user characteristic).
- *Extensible*. Since the accessibility assessment procedures change (mostly to enforce better analyses), the framework should support the application of different procedures.
- *Fine-grained*. As discussed earlier, current accessibility evaluation practices are black-boxed, leading to having just a general view of evaluation results. The framework should support fine-grained analyses, to support studying accessibility from the perspective of different audiences.
- *Scalable*. The framework should not impose limits to the size and complexity of encoded information (i.e., knowledge base).

Each component is defined through a specific OWL-based vocabulary, as the inclusion of already existing ontologies (mostly specified in OWL) lowers the burden of defining each component of the framework. Accordingly, we have developed this framework by extending the EARL ontology to support the elicited requirements. Next, each component of the framework is described in more detail. For details about the namespace prefixes used in the next Sections and their corresponding URI mappings, please consult the Appendix. Throughout this Section we will provide examples on how to describe accessibility knowledge based on the Notation 3 (N3) syntax (Berners-Lee, 2006).

Web Graphs

The first component in the framework relates to the specification of Web graphs. The goal of this component is to represent each Web page as a single resource, as well as its corresponding hyperlinking structure. Figure 2 presents the concepts that support the specification of Web graphs.

The main subject of constructing Web graphs is the Web page. Since the EARL specification only supports the specification of subjects that are available on the Web (*earl:Content* class), we have further refined the concept to limit its scope just to Web pages (the core subject of accessibility assessment procedures), through the *ev:Webpage* class.

Figure 1. Web accessibility knowledge framework

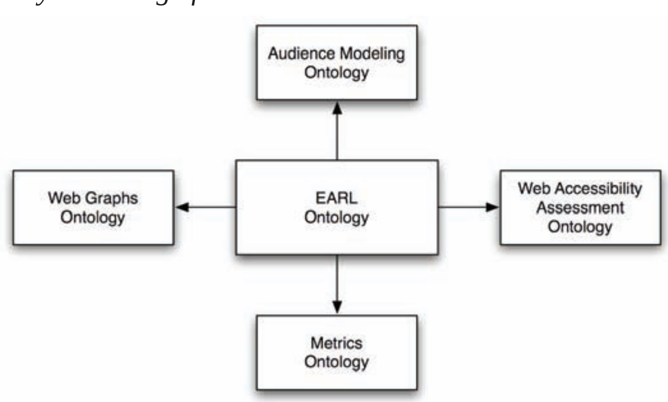

Figure 2. Web graphs ontology

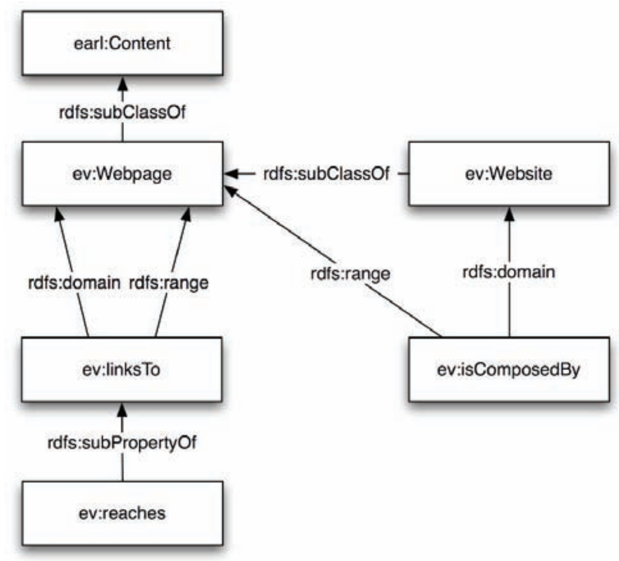


Other types of content, such as images and CSS stylesheets (Bos, Çelik, Hickson, & Lie, 2007), were considered inherent of each Web page, from the perspective of evaluation procedures.

Two main properties (and their inverse) were defined to specify hyperlinks. The first, *ev:linksTo* (and its corresponding inverse property, *ev:islinkedBy*) establishes the direct relationship between two Web pages. The second property, *ev:reaches* (and its inverse, *ev:isReachedBy*), extends *ev:linksTo* with a transitive characteristic. This way, it becomes possible to query Web graphs from the perspective of reachability between two (or more) Web pages, not just on direct linking properties. This property will only afford knowing whether two Web pages are indirectly connected, leaving outside of the scope the number of links in between them. We have opted to explicitly define inverse properties, to afford the specification of queries that are more expressive and closer to natural language. To complement these constructs, we have specified the *ev:Website* class that, in conjunction with the *ev:isComposedBy* property (and its inverse, *ev:composes*), affords the direct specification of which Web pages belong to the same Website. To support out-of-the-box the specification of hyperlinking structure for Web sites, we have defined that *ev:Website* extends the *ev:Webpage* concept. However, the ontology cannot enforce the semantics that if two Web pages are linked, then their corresponding Web sites are also linked. Hence, we have devised two rules in SWRL (Horrocks et al., 2004) to afford linking scenarios, as presented next:

```
ev:linksTo(?website1, ?website2) =>
    ev:isComposedBy(?website1, ?webpage1) &
    ev:isComposedBy(?website2, ?webpage2) &
    ev:linksTo(?webpage1, ?webpage2)

ev:reaches(?website1, ?website2) =>
    ev:isComposedBy(?website1, ?webpage1) &
    ev:isComposedBy(?website2, ?webpage2) &
    ev:reaches(?webpage1, ?webpage2)
```

Next, we present a small example of how to define Web graphs, formally expressed (in the N3 format):

```
@base <http://example.com/>.

<b.html> a ev:Webpage.
<c.html> a ev:Webpage.
<a.html> a ev:Webpage;
    ev:linksTo <b.html>;
    ev:linksTo <c.html>.

<> a ev:Website.
<> ev:isComposedBy <a.html>;
 ev:isComposedBy <b.html>;
 ev:isComposedBy <c.html>.
```

Web Accessibility Assessment

The essential aspects for accessibility assessment results concern the description of the tests and their resulting outcome of applying them to a Web page. Consequently, the EARL ontology affords an extensible way of describing Web accessibility assessment results, in the form of *earl:Assertion* predicates. This includes, amongst other predicates, the specification of which test is being applied (i.e., *earl:TestCase*) and what is the result of its application to the Web page that its being evaluated (i.e., *earl:TestResult*).

In the second component of our framework, we have extended the EARL predicates for accessibility assessment by refining test cases (i.e., *earl:TestCase*) with appropriate semantics about the nature of the tests, regarding the different technologies used in Web pages. This will afford the fine-grained analysis of Web pages according to technological criteria, as depicted by the concepts in Figure 3.

The main predicates for describing the nature of the tests are: *ev:TestContent*, for the specification of tests applied to the actual contents (in different media) of Web pages; *ev:Structure*, for tests applied directly on the HTML structure itself; *ev:Style*, when testing styling properties (such as analyzing CSS); and *ev:Behavior*, to represent tests over scripts (e.g., Javascript).

To better illustrate the usage of this ontology, we present next a classification of some WCAG 1.0 guidelines:

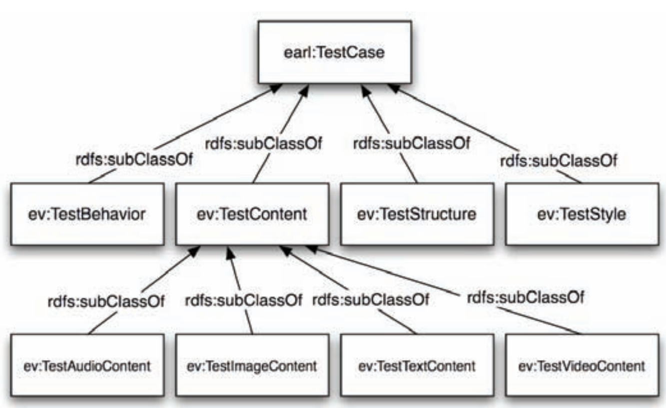
```
@prefix wcag10: <http://www.w3.org/TR/
WCAG10/#>.

wcag10:gl-color a ev:TestStyle.
wcag10:gl-structure-presentation a evTest-
Structure.
wcag10:gl-structure-presentation a evTest-
Style.
```

Audiences

We have defined a third component in our ontological framework to support the specification of audiences. This will ensure that different queries can be performed to a knowledge base of Web

Figure 3. Web accessibility assessment ontology



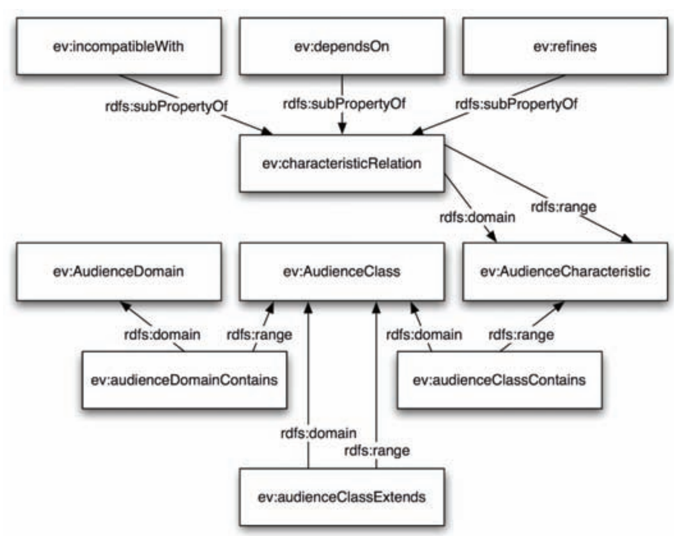
accessibility assessment according to the necessities and characteristics of different audiences. We based this support on earlier works on audience modeling, such as those described in Lopes & Carriço (2008a). Figure 4 depicts the complete ontological vocabulary to describe audiences (for simplicity, inverse properties are omitted).

The atomic concept in this vocabulary is *ev:AudienceCharacteristic*. Its purpose is to represent a single concept of an audience (e.g., a specific disability, a device characteristic, etc.). Since characteristics may represent concepts at different abstraction levels, they should be structured taxonomically. We introduce the *ev:refines* property (and its inverse, *ev:isRefinedBy*) to afford this expressivity.

The inherent nature of audiences raises the fact that they are often defined by several characteristics. Accordingly, this vocabulary introduces *ev:AudienceClass* as a way to represent them, along the side of the *ev:audienceClassContains* property (and its inverse, *ev:audienceCharacteristicIsContainedBy*) to map characteristic inclusion by an audience. However, since this association is merely syntactic, incoherent audiences might be described. To mitigate such issues we have introduced two additional concepts in the vocabulary. The first, *ev:dependsOn*, affords mapping dependencies between characteristics (such as total blindness depends on screen reader). The second, *ev:incompatibleWith*, allows the specification of incompatibilities between characteristics (e.g., total blindness is incompatible with screen). With these two properties, the semantics of audiences can be verified automatically. These properties, in conjunction with *ev:refines*, form the set of semantic relations that can be established between characteristics. Therefore, we introduce a generalization concept, *ev:characteristicRelation*, as an abstraction for the three concepts. This term affords inferring, e.g., if two characteristics have any kind of dependency between them.

While analyzing Web graphs from the perspective of a single audience can provide interesting results, the scope of such results is limited. It is often to perform comparative analyses of the results for a set of audiences. To support such scenarios, we have defined an audience aggregation concept, *ev:AudienceDomain*, to represent the domain of audiences that will be analyzed. The inclusion of an audience by a domain is represented through the *ev:audienceDomainContains* property (and corresponding inverse, *ev:audienceClassIsContainedBy*).

Figure 4. Audiences ontology



Lastly, we introduce in this vocabulary another concept to explore the synergies and differences between audiences, through the *ev:audienceClassExtends* property (and its *ev:audienceClassIsExtendedBy* counterpart). This extension mechanism is based on traditional object oriented modeling practices, i.e., an audience that extends another audience inherits its characteristics, thus creating parent-child relationships between audiences within a domain. Moreover, due to the fact that characteristics are taxonomically organized (through the *ev:refines* property), the characteristics of child audiences can be inferred and generalized to their common parent audience. A simple example follows, where a small taxonomy of characteristics is defined, and used in the definition of an audience domain.

```
@prefix tx: <http://taxonomy.com/>.
@prefix au: <http://audiences.com/>.

tx:characteristic a
ev:AudienceCharacteristic.
tx:disability a ev:AudienceCharacteristic.
tx:blind a ev:AudienceCharacteristic.
tx:totallyBlind a ev:AudienceCharacteristic.
tx:colorBlind a ev:AudienceCharacteristic.
tx:device a ev:AudienceCharacteristic.
tx:screen a ev:AudienceCharacteristic.

tx:disability ev:refines tx:characteristic.
tx:blind ev:refines tx:disability.
tx:totallyBlind ev:refines tx:blind.
tx:colorBlind ev:refines tx:blind.
tx:device ev:refines tx:characteristic.
tx:screen ev:refines tx:device.

tx:totallyBlind ev:incompatibleWith
tx:colorBlind.
tx:totallyBlind ev:incompatibleWith
tx:screen.
tx:colorBlind ev:dependsOn tx:screen.

au:domain1 a ev:AudienceDomain.

au:blind a ev:AudienceClass.
au:blind ev:audienceClassContains tx:blind.
au:domain1 ev:audienceDomainContains
au:blind.

au:totallyBlind a ev:AudienceClass.
au:totallyBlind ev:audienceClassContains
tx:totallyBlind.
au:domain1 ev:audienceDomainContains
au:totallyBlind.

au:colorBlind a ev:AudienceClass.
au:colorBlind a ev:audienceClassContains
tx:colorBlind.
au:colorBlind a ev:audienceClassContains
tx:screen.
au:domain1 ev:audienceDomainContains
au:colorBlind.

au:totallyBlind ev:audienceClassExtends
au:blind.
au:colorBlind ev:audienceClassExtends
au:blind.
```

However, affording the description of audience domains has limited applicability. To ensure that queries on Web graphs can be formulated based on the characteristics of audiences, there must be a mapping between audiences and accessibility assessment tests. Such vocabulary is synthesized in Figure 5.

In this vocabulary we have introduced a single property, *ev:requiresCharacteristic* (and its corresponding *ev:isRequiredByTest* counterpart), that maps a characteristic to a particular *earl:TestCase* instance. With this property, any audience or even entire domain can be mapped to the battery of tests that must be performed to a Web page, in order to obtain results tailored to these audiences. Dually, if the entire set of tests is performed over each Web page, their results can be queried from the perspective of different audiences or entire domains. An example follows, where the two previous examples are bound together. More spe-

Figure 5. Audience/test mapping sub-ontology

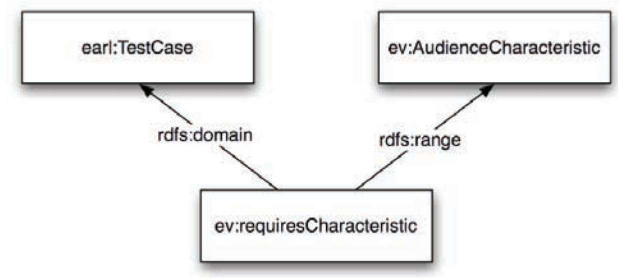


Figure 6. Metrics ontology

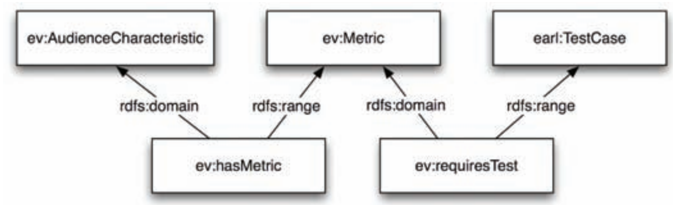

cifically, we map test cases to concrete audience characteristics that have been defined.

```

@prefix tx: <http://taxonomy.com/>.

wcag10:gl-color ev:requiresCharacteristic tx:colorBlind.
wcag10:gl-structurePresentation ev:requiresCharacteristic tx:totallyBlind.
```

Metrics

The last component in the framework concerns the specification of Web accessibility metrics, i.e., providing quantitative information about the accessibility of a Web page. Since different metrics can be applied to evaluation results, a supportive vocabulary for the specification of metrics must be extensible. This way, Web graphs can also be analyzed from the perspective of different metrics, thus allowing exploring which metric is better suited to different accessibility scenarios. Figure 6 depicts the vocabulary to support the specification of metrics.

The main concept in the metrics vocabulary is *ev:Metric*. Its purpose is to afford the specification of metrics that are applied to each Web page, based on the results of corresponding tests. While some metrics might be independent from specific tests, more concrete metrics can depend on the application of them. Therefore, we introduce the *ev:requiresTest* property to define dependency binds between metrics and tests (and its counterpart, *ev:isRequiredByMetric*). This property can be used, e.g., to specify consistency verification rules on the application of metrics, based on their semantics. Furthermore, by crossing this property with the *ev:requiresCharacteristic*, metrics can be mapped indirectly to audience characteristics. However, metrics can also be directly related to audience characteristics. This affords tying up specific quantification procedures to characteristics. Hence, we introduce an extra property in the vocabulary, *ev:hasMetric*, in order to support this type of scenarios. Next, we present a simple example on how to bind metrics with tests and characteristics.

```
@prefix wcag10: <http://www.w3.org/TR/WCAG10/#>.
@prefix m: <http://example.com/metrics#>.
@prefix tx: <http://taxonomy.com/>.

m:simpleMetric a ev:Metric;
    ev:requiresTest wcag10:gl-color;
    ev:requiresTest wcag10:gl-structurePresentation.

m:charMetric a ev:Metric.

tx:colorBlind ev:hasMetric m:charMetric.
```

We have introduced another concept on the vocabulary that is crucial to the specification of metrics. Each metric is supposed to have a concrete value, when applied to a Web page. Therefore, the vocabulary provides support to this feature through the *ev:hasMetricValue* datatype property, where metric values can be setup in the [0, 1] range (i.e., percentage). This way, since each metric does not yield an absolute value, Web graphs can be compared in the perspective of different metrics. With these constructs, the framework provides the support for specifying the resulting application of a given metric, in the context of an accessibility evaluation procedure. However, it is out of the scope of this Chapter to describe how these metrics are calculated (cf. Vigo et al., 2007a).

Consequently, since this property is abstract, concrete metrics properties must be derived from *ev:hasMetricValue* through subclassing. This extension to the metrics ontology is depicted in Figure 7.

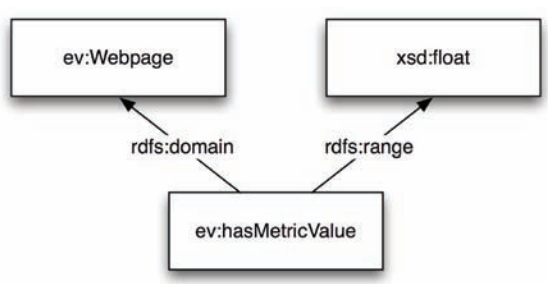
As a simple example, we present how to use this extension to the metrics ontology, by specifying a new datatype property, as well as its application in a concrete set of Web pages.

```
@prefix m: <http://example.com/metrics#>.
@base <http://example.com/>.
m:hasSimpleMetricValue rdfs:subPropertyOf ev:hasMetricValue.
<a.html> m:hasSimpleMetricValue 0.2.
<b.html> m:hasSimpleMetricValue 0.9.
<c.html> m:hasSimpleMetricValue 0.45.
```

However, with these constructs it is impossible to know what are the metric values associated with a specific characteristic or test case, for a given Web page. This happens due to *ev:Metric* instances are not automatically bound to datatype properties derived from *ev:hasMetricValue*. Consequently, query patterns cannot be created to explore complex mining scenarios, as each binding between metrics and datatype properties have to be artificially created on each query, which poses sever limitations on the generalization requirement for querying Web accessibility. In order to mitigate this situation, we defined another property, *ev:relatesToMetric* (and its counterpart, *ev:isRelatedToDatatypeProperty*), to draw both concepts together, as depicted in Figure 8.

Since we wanted to bind a datatype property directly to an *ev:Metric* instance, we had to import the OWL schema into our own ontology. This is due to the fact that, per definition, object properties bind class instances. Because *ev:hasMetricValue* (and subclassed datatype properties) are *owl:DatatypeProperty* instances, we circumvented this to afford the specification of richer and more complex query patterns that can remain agnostic to particular concepts or instances.

Figure 7. Metrics ontology extension



To exemplify the usage of this property, we have bound a metric instance to a particular datatype based on the previous examples, as shown next.

```
@prefix m: <http://example.com/metrics#>.

m:hasSimpleMetricValue  ev:relatesToMetric
m:simpleMetric.
```

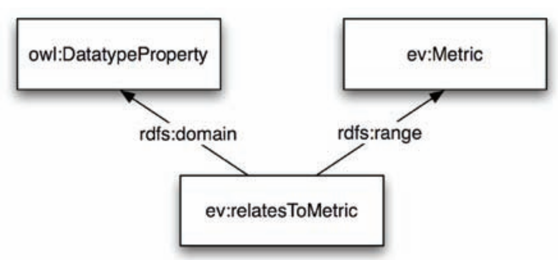
However, by setting *ev:relatesToMetric*'s domain to a generic OWL construct, one can bind metrics to any datatype property as there is no formal way to restrict the domain just to datatype properties derived from *ev:hasMetricValue*. To mitigate this issue, there must be an appropriate semantic enforcement through rules. The following SWRL rule affords this scenario:

```
ev:relatesToMetric(?datatypeProperty, ?metric) =>
    owl:subPropertyOf(?datatypeProperty,
ev:hasMetricValue)
```

QUERY PATTERNS

The extensions to the EARL ontology that we presented in the previous Section provide a comprehensive set of concepts that afford the full description of Web graphs from the perspective of Web accessibility and audience richness. This framework serves as the base ground for setting up Web graph knowledge bases that can be semantically queried in different forms. From the vast range of Semantic Web querying technologies, we opted to specify queries in the SPARQL language (Prud'hommeaux & Seaborne, 2008), as it is the *de facto* querying standard in the Semantic Web stack.

Figure 8. Metrics binding scheme



All examples in this Section will be based on the following SPARQL prefixes mapping:

```
PREFIX earl: < http://www.w3.org/ns/earl#>
PREFIX ev: <http://hcim.di.fc.ul.pt/ontologies/evaluation#>
PREFIX m: <http://example.com/metrics#>
PREFIX tx: <http://taxonomy.com/>
PREFIX au: <http://audiences.com/>
PREFIX wcag10: <http://www.w3.org/TR/WCAG10/#>
```

In this chapter, we have distinguished two different types of query patterns than can be applied to Web graphs: mining properties, and partitions extraction. Next, we describe each one of these pattern types.

Mining Web Site Properties

Web sites on their own can be analyzed from several perspectives. In this Section, we present some query patterns that can extract relevant information about a single Web page, as well as a set of Web pages perceived as one single entity (i.e., Web site). For practical purposes, all SPARQL patterns are applied to a dummy Web page (*http://example.com/a.html*) or Web site (*http://example.com*), whose semantics are marked as *ev:Webpage* and *ev:Website* instances, correspondingly; other instances that appear on queries are based on the examples presented in the previous Sections.

Metric thresholds. One of the simplest ways of verifying the accessibility of a single Web page relates to setting up quality thresholds. We have devised several query patterns for this purpose. The simplest query concerns a strict threshold that yields whether a Web page has a minimum quality level for a specific metric:

```
ASK {
    <http://example.com/a.html>
    m:hasSimpleMetricValue ?v.
    FILTER (?v >= 0.5)
}
```

Based on this pattern, one can generalize it for minimum and maximum boundaries, thus allowing checking if a Web page belongs to a particular quality cluster:

```
ASK {
    <http://example.com/a.html>
    m:hasSimpleMetricValue ?v.
    FILTER(?v >= 0.5 && ?v <= 0.75)
}
```

On the other hand, thresholds can be used to understand what metrics are above a certain value (or between two boundaries). Along these lines, the previous query pattern can be rewritten as:

```
SELECT ?metric
WHERE {
    <http://example.com/a.html> ?metricValue
    ?v.
    ?metricValue ev:relatesToMetric ?metric.
    FILTER (?v >= 0.5 && ?v <= 0.75)
}
```

Content quality. Another aspect that can be explored in a Web page deals with the semantics of the tests applied to it. In conjunction with metric value filtering, one can grasp the quality of a Web page based on the semantic categorization of test cases:

```
ASK {
    <http://example.com/a.html> ?metricValue
    ?v.
    ?metricValue ev:relatesToMetric ?metric.
    ?metric ev:requiresTest ?test.
    ?test rdfs:subClassOf
    ev:TestImageContent.
    FILTER (?v >= 0.5)
}
```

This query pattern can be extended to find out which types of test cases have an inherent quality above a given threshold (the DISTINCT query modifier has been used to remove duplicates):

```
SELECT DISTINCT ?testType
WHERE {
    <http://example.com/a.html> ?metricValue
    ?v.
    ?metricValue ev:relatesToMetric ?metric.
    ?metric ev:requiresTest ?test.
    ?test rdfs:subClassOf ?testType.
    FILTER (?v >= 0.5)
}
```

Characteristic quality. As explained earlier, characteristics can be bound to metrics. This feature of the framework allows the exploration of quality metrics similar to *metric thresholds*, but taking into account characteristics as the main feature to be analyzed:

```
ASK {
    <http://example.com/a.html> ?prop ?v.
    tx:colorBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

This pattern can be extended in order to leverage which characteristics have a quality level above a certain threshold:

```
SELECT ?char
WHERE {
    <http://example.com/a.html> ?prop ?v.
    ?char ev:hasMetric ?metric.
```

```
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

By having a quality mark associated to characteristics, these can also be compared, to verify which one is better supported in a Web page. This can be directly achieved with the following query pattern:

```
ASK {
    <http://example.com/a.html> ?prop1 ?v1.
    <http://example.com/a.html> ?prop2 ?v2.
    tx:colorBlind ev:hasMetric ?metric1.
    tx:totallyBlind ev:hasMetric ?metric2.
    ?metric1 ev:isRelatedToDatatypeProperty
    ?prop1.
    ?metric2 ev:isRelatedToDatatypeProperty
    ?prop2.
    FILTER (?v1 > ?v2)
}
```

Furthermore, both patterns can be combined to extract which characteristics have a better quality than a predetermined one:

```
SELECT ?char
WHERE {
    <http://example.com/a.html> ?prop1 ?v1.
    <http://example.com/a.html> ?prop2 ?v2.
    tx:colorBlind ev:hasMetric ?metric1.
    ?char ev:hasMetric ?metric2.
    ?metric1 ev:isrelatedToDatatypeProperty
    ?prop1.
    ?metric2 ev:isrelatedToDatatypeProperty
    ?prop2.
    FILTER (?v1 > ?v2)
}
```

Audience quality. One of the important aspects discussed earlier pertains to knowing if a Web page has a certain degree of quality in what respects to a particular audience. The previous query pattern can be adapted to support this feature:

```
ASK {
    <http://example.com/a.html> ?prop ?v.
    au:totallyBlind ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

While this query pattern affords the explicit verification of the quality of a given audience, it is also relevant to explore and infer which audiences are supported in a Web page, with a given quality level. This pattern can be translated into SPARQL as:

```
SELECT ?audience
WHERE {
    <http://example.com/a.html> ?prop ?v.
    ?audience ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

Domain quality. In the same fashion as the previous patterns, one can obtain information about whether a domain is supported by a Web page or not, according to a specific threshold:

```
ASK {
    <http://example.com/a.html> ?prop ?v.
    au:domain1 ev:audienceDomainContains
    ?audience.
    ?audience ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
```

```
    ?prop.
    FILTER (?v >= 0.5)
}
```

In the case where one wants to discover which domains are above a given threshold, the previous query pattern can be adapted in a simple way to cope with this requirement, as follows:

```
SELECT ?domain
WHERE {
    <http://example.com/a.html> ?prop ?v.
    ?domain  ev:audienceDomainContains
    ?audience.
    ?audience  ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

Website quality. While all of the previous patterns are targeted just to a single Web page, it is relevant to find out information about the set of Web pages from a unique entity point of view (e.g., a Web site). By exploring the Web graph ontology provided in the framework, Web sites can be analyzed as a single entity:

```
SELECT ?page
WHERE {
    ?page  ev:composes  <http://example.
    com>.
}
```

More complex patterns can be devised for Web sites, based on this pattern and the set of patterns presented above for Web pages. For instance, combining this pattern with characteristic quality analysis, Web sites can be analyzed to find out which ones are entirely accessible for any audience characteristic above a certain threshold:

```
SELECT ?site
WHERE {
    ?site ev:isComposedBy ?page.
    ?page ?prop ?v.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

A variant on this query pattern can be defined as verifying if the average metric value is above the threshold, for a given characteristic. This would unify Web pages, thus analyzing a Web site as a single entity. However, SPARQL does not provide aggregation functions out of the box. Therefore, some implementations have circumvented this issue through, e.g., the AVG function. Without this function each metric value should be aggregated outside the query pattern and an average value calculation should be performed, which influences its scalability. Hence, this pattern uses the AVG function accordingly:

```
SELECT AVG(?v)
WHERE {
    <http://example.com>  ev:isComposedBy
    ?page.
    ?page ?prop ?v.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric:isRelatedToDatatypeProperty
    ?prop.
}
```

Semantically Extracting Web Graph Partitions

While capturing information about the accessibility of single Web pages or Web sites has value, it is more interesting to analyze Web graphs as a whole. The set of query patterns presented in the previous Section can be adapted to grasp new knowledge about entire Web graphs. In this

Section we present query patterns that afford the extraction of Web graph partitions according to accessibility criteria. Along the lines of the previous Section, all SPARQL patterns are applied to a set of dummy Web pages (e.g., *http://example.com/a.html*) or Web site (*http://example.com*), with the semantics of *ev:Webpage* and *ev:Website*, correspondingly; other instances that appear on queries are based on the examples presented in the previous Sections.

Reachability. The simplest information that can be obtained about a Web graph concerns its edges, i.e., the link structure. Edges are described through *ev:linksTo* property instances. The transitiveness of the *ev:reaches* property, based on *ev:linksTo*, allows the exploration of connectivity between Web pages (and between Web sites, as well). This query pattern will be used as the base support for extracting Web graph portions according to different accessibility semantics. Reachability can be a property queried between Web pages, e.g.:

```
ASK {
    <http://example.com/a.html>  ev:reaches
    <http://example.com/b.html>.
}
```

This notion can be extended to explore which Web pages can be reached from a starting point:

```
SELECT ?page
WHERE {
    <http://example.com/a.html>  ev:reaches
    ?page.
}
```

The opposite pattern, knowing which Web pages reach a specific ending point, can also be explored similarly:

```
SELECT ?page
WHERE {
    ?page ev:reaches <http://example.com/a.
    html>.
}
```

Lastly, based on these queries, Web graph portions can be extracted according to their linking structures. For these patterns, we use the CONSTRUCT query form provided in SPARQL. The simplest graph portion extraction concerns finding out the linking structure reached from a specific starting Web page:

```
CONSTRUCT {
    ?page ev:linksTo ?otherpage
}
WHERE {
    <http://example.com/a.html>  ev:reaches
    ?page.
    ?page ev:linksTo ?otherPage.
}
```

By generalizing this query pattern, the entire information about a particular Web graph portion can be extracted. While we could use the DESCRIBE query form, we opted to use CONSTRUCT since it is required to be supported in every SPARQL implementation. The query pattern is as follows:

```
CONSTRUCT {
    ?page ?prop ?value
}
WHERE {
    <http://example.com/a.html>  ev:reaches
    ?page.
    ?page ?prop ?value.
}
```

Lastly, all of these patterns can be further extended towards a macroscopic level, i.e., not centered on Web pages per se, but on Web sites. It is important to understand graph connectivity at this level, e.g. whether a Web site directly links to another one:

```
ASK {
    <http://example.com>  ev:isComposedBy
    ?page.
    <http://example2.com>  ev:isComposedBy
    ?page2.
    ?page ev:linksTo ?page2.
}
```

Based on this pattern, it might be relevant to understand what are the linking sources in such cases:

```
SELECT ?page
WHERE {
    <http://example.com>  ev:isComposedBy
    ?page.
    <http://example2.com>  ev:isComposedBy
    ?page2.
    <page ev:linksTo ?page2.
   }
```

Expanding further, one is able to find out which Web sites link directly to a given Web site:

```
SELECT ?site
WHERE {
    ?site ev:isComposedBy ?page.
    <http://example.com>  ev:isComposedBy
    ?page2.
    ?page ev:linksTo ?page2.
}
```

This type of pattern can be applied to all of the subsequent query patterns accordingly. For simplicity purposes, each one of the next query patterns is applied to Web pages.

Common characteristics. Based on the characteristics quality pattern for Web pages and Web sites, the same type of information can be acquired from entire Web graphs. Here, a quality threshold dictates which characteristics are above it in the entire Web graph:

```
SELECT ?char
WHERE {
    ?page ?prop ?v.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

Based on this query pattern, Web graphs can be partitioned according to characteristic-oriented quality thresholds, following the same rules presented above:

```
CONSTRUCT {
    ?page ?prop ?value
}
WHERE {
    ?page rdf:type ev:Webpage.
    ?page ?prop ?value.
    ?char ev:hasMetric ?metric.
    ?metric ev:isrelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

While this last pattern extracts the entire RDF graph, there are cases where just the corresponding Web graph structure (i.e., just the Web pages and linking structure) is extracted. In these cases the pattern can be easily adjusted as follows:

```
CONSTRUCT {
    ?page ev:linksTo ?otherPage.
}
WHERE {
    ?page ev:linksTo ?otherPage.
    ?page ?prop ?value.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

Common audiences. The same type of query pattern can be applied to find out if a given Web graph is tailored to a specific audience:

```
ASK {
    ?page ?prop ?value.
    au:totallyBlind ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

Based on this query pattern, the Web graph itself can be partitioned according to this specific semantics:

```
CONSTRUCT {
    ?page ?prop ?value
}
WHERE {
    ?page rdf:type ev:Webpage.
    ?page ?prop ?value.
    au:totallyBlind ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

Characteristic reachability. This query pattern has been devised to find out which Web pages can be reached from a starting point, while maintaining a quality level above a specific threshold for a given characteristic:

```
SELECT ?page
WHERE {
    <http://example.com/a.html> ev:reaches
    ?page.
    ?page ?prop ?value.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

However, the way this query pattern has been devised misses the intermediate Web pages that might not have the desired quality level for the selected characteristic. To mitigate this issue, all intermediate Web pages have to be verified accordingly:

```
SELECT ?otherPage
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5 && ?value2 >=
    0.5)
}
```

Accordingly, this pattern can be adapted to extract the corresponding Web graph portion. This is done by creating an RDF graph consisting of *ev:linksTo* derived triples, where both end-points have to be reached from the starting point, as follows:

```
CONSTRUCT {
    ?page ev:linksTo ?otherPage
}
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
```

```
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5 && ?value2 >=
    0.5)
}
```

This last version of the query pattern can be further adapted to find out just whether there are any Web pages that cannot be reached according to the devised semantics:

```
ASK {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypePropery
    ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

If one wants to know what Web pages are not reached through this method, the previous version of the query pattern can be further adapted. Please notice that this version of the pattern simply inverts the filter, in comparison with the second version of this query pattern:

```
SELECT DISTINCT ?page
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    tx:totallyBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypePropery
    ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

Audience reachability. As audiences are more closely representative of users (by aggregating characteristics), it is also important to study the graph reachability from this point of view. The simplest query pattern for audience reachability concerns finding out what Web pages are appropriate for a specific audience:

```
SELECT ?page
WHERE {
    <http://example.com/a.html> ev:reaches
    ?page.
    ?page ?prop ?value.
    au:totallyBlind ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5)
}
```

Like in characteristics reachability, one has to take into account that all Web pages in between must also have a quality level above the threshold that has been set. Accordingly, this query pattern must cope with this issue:

```
SELECT ?otherPage
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:totallyBlind ev:audienceClassContains
    ?char.
```

```
    ?char ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty ?prop.
    FILTER (?value >= 0.5 && ?value2 >= 0.5)
}
```

This pattern version can be easily adapted towards extracting the corresponding Web graph partition:

```
CONSTRUCT {
    ?page ev:linksTo ?otherPage
}
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches ?page.
    <http://example.com/a.html> ev:reaches ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:totallyBlind ev:audienceClassContains ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty ?prop.
    FILTER (?value >= 0.5 && ?value2 >= 0.5)
}
```

It is also possible to build on this query pattern version to find out if there is any Web page that cannot be reached with at least the same quality level:

```
ASK {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches ?page.
    <http://example.com/a.html> ev:reaches ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:totallyBlind ev:audienceClassContains ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypePropery ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

Likewise, we can also extract from the Web graph the set of Web pages that cannot be reached according to this semantics:

```
SELECT DISTINCT ?page
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches ?page.
    <http://example.com/a.html> ev:reaches ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:totallyBlind ev:audienceClassContains ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypePropery ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

Domain reachability. Along the lines of the previous two patterns, it is important to find out what partitions of a Web graph are reached from a starting point for all audiences within an audience domain, according to a previously set quality level threshold. The patterns for domain reachability follow closely the ones for characteristic and audience reachability. Therefore, we present a query pattern representative of the specific details for domain reachability. The following pattern affords the extraction of a Web graph partition for all the Web pages that are reachable from a starting point, based on a quality threshold:

```
CONSTRUCT {
    ?page ev:linksTo ?otherPage.
}
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:domain1 ev:audienceDomainContains
    ?audience.
    ?audience ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty
    ?prop.
    FILTER (?value >= 0.5 && ?value2 >=
    0.5)
}
```

Another interesting pattern for domain reachability concerns finding out whether an audience domain has any audience that limits the reachability property:

```
ASK {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:domain1 ev:audienceDomainContains
    ?audience.
    ?audience ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty
    ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

This query pattern can be further converted to find out what are these audiences. This way, researchers can ask what are the specific audiences that limit reachability. This pattern is as follows:

```
SELECT ?audience
WHERE {
    ?page ev:linksTo ?otherPage.
    <http://example.com/a.html> ev:reaches
    ?page.
    <http://example.com/a.html> ev:reaches
    ?otherPage.
    ?page ?prop ?value.
    ?otherPage ?prop ?value2.
    au:domain1 ev:audienceDomainContains
    ?audience.
    ?audience ev:audienceClassContains
    ?char.
    ?char ev:hasMetric ?metric.
    ?metric ev:relatesToDatatypeProperty
    ?prop.
    FILTER (?value < 0.5 && ?value2 < 0.5)
}
```

Inward linking quality. As explained before, one of the great powers of the Web resides on how its linking structure is perceived and navigated by users. One important aspect of this property concerns the quality of the Web graph from the perspective of how Web sites are linked to each other. This query pattern explores linking to a specific ending point, i.e., all Web pages that link to a target Web page. First, it is important to extract the graph partition composed by the Web pages that point to it:

```
CONSTRUCT {
    ?page ev:linksTo <http://example.com/a.
    html>
}
WHERE {
    ?page ev:linksTo <http://example.com/a.
    html>.
}
```

Based on this simple query, quality thresholds can be set according to one of the query patterns presented in the previous Section (i.e., patterns for Web pages and Web sites), e.g., for characteristics:

```
CONSTRUCT {
    ?page ev:linksTo <http://example.com/a.
    html>
}
WHERE {
    ?page ev:linksTo <http://example.com/a.
    html>.
    ?page ?prop ?v.
    tx:colorBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= 0.5)
}
```

While this pattern query is interesting for extracting the Web graph based on a predetermined threshold, it is more important to extract it based on the quality of the target Web page. This query pattern can be further extended accordingly:

```
CONSTRUCT {
    ?page ev:linksTo <http://example.com/a.
    html>
}
WHERE {
    ?page ev:linksTo <http://example.com/a.
    html>.
    ?page ?prop ?v.
    <http://example.com/a.html> ?prop ?v2.
    tx:colorBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v >= ?v2)
}
```

Another aspect that can be explored based on this last version of the query pattern concerns knowing whether the target Web page has better quality than the Web pages that point to it. This allows us to understand if the target Web page can be perceived as an accessibility haven on navigation tasks:

```
ASK {
    ?page ev:linksTo <http://example.com/a.
    html>.
    ?page ?prop ?v.
    <http://example.com/a.html> ?prop ?v2.
    tx:colorBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (?v < ?v2)
}
```

Outward linking quality. Dually to the previous query pattern, it is also important to understand the linking quality by setting up an initial starting Web page and explore the Web pages that it links to. The type of queries in this pattern follows closely the previous set of patterns with small changes. For instance, the following query leverages the Web graph partition of the Web pages that are safe to navigate:

```
CONSTRUCT {
    <http://example.com/a.html>  ev:linksTo
    ?page.
}
WHERE {
    <http://example.com/a.html>  ev:linksTo
    ?page.
    ?page ?prop ?v.
    <http://example.com/a.html> ?prop ?v2.
    tx:colorBlind ev:hasMetric ?metric.
    ?metric ev:isRelatedToDatatypeProperty
    ?prop.
    FILTER (v? >= ?v2)
}
```

Verticality. It is a fact that the Web is partially tailored to specific accessibility situations, e.g., “accessible versions” of a Web site. This property can be explored by studying the verticality of Web graphs. For example, given two different characteristics and a quality threshold, there might be an overlap between which Web pages are accessible to both. The amount of Web pages in this situation is directly related to the verticality of their corresponding partitions. This is done through the following query pattern:

```
SELECT ?page
WHERE {
    ?page ?prop1 ?value1.
    ?page ?prop2 ?value2.
    tx:colorBlind ev:hasMetric ?metric1.
    tx:totallyBlind ev:hasMetric ?metric2.
    ?metric1 ev:isRelatedToDatatypeProperty
    ?prop1.
    ?metric2 ev:isRelatedToDatatypeProperty
    ?prop2.
    FILTER (?value1 >= 0.5 && ?value2 >=
    0.5)
}
```

FUTURE TRENDS

The framework presented in this chapter is just one of the initial steps that can help understanding the impact of Web accessibility and Web standards on users, in a large scale (i.e., the *whole* Web) and with a fine-grained control over what aspects of Web accessibility and users are to be studied. We envision that semantic technologies can disrupt the way Web developers and designers think of accessibility and its social impact in the way users feed and consume information of the Web.

To grasp this knowledge, the framework we presented must be supported by its implementation and use in the analysis of large portions of the Web. Hence, we foresee that the following trends will help in this complex task:

- *Scalable architectures.* Building large scale Web accessibility observatories require scale-free approaches to crawl, store, process, and query the Web. We expect that with ongoing and future developments of scalable architectures that can cope with these type of tasks will help providing further insights on the influence that the Web's structure poses on Web accessibility issues.
- *Graph visualization algorithms.* There is a need for visualize large quantities of data (e.g., billions of metadata of Web pages), to grasp Web accessibility knowledge from semantic queries over Web graphs. Even when intelligent ways of extracting information from Web graph accessibility data, coping with billions of Web pages is not trivial. New graph visualization techniques can help lowering the burden of *finding the needle in the haystack*, i.e., the relevant information about the impact of Web accessibility at a large scale.
- *Automated verification.* Experts verify usability and accessibility problems in a manual/guided fashion. Since this approach is scale-bounded, there is the need for new automated verification procedures. With the advance in this research field (most probably with the aid of semantic technologies), more information can be obtained about usability and accessibility problems of the Web at a large scale. Significant advances to this challenge include understanding better how humans interact with computers, new models and theories for human psychology, as well as more pragmatic approaches such as statistical content analysis.
- *Metrics.* Accurate metrics provide better answers for finding the impact of Web accessibility implementation for all users. Having a base framework such as the one we presented in this chapter will help com-

paring metrics (and their corresponding application to Web graphs) and improve their accuracy.

- *Predictive and evolutionary models.* By having available smart models, the Web can be studied from predictive and evolutionary perspectives, opening the way to improving Web standards and Web accessibility assessment tools.

With advancements on these fronts, we foresee that the work described in this chapter can be put together within existing Web crawling, indexing and searching facilities with minor tweaks, forming an architecture for large scale Web accessibility assessments, as presented in Figure 9.

In this architecture the central aspect resides on the *Web accessibility results* repository, which should follow the metadata structures defined in this chapter. This repository holds all information about the accessibility semantics of the Web graph, as grasped by *Accessiblity Spiders* (similar to Web crawler's spiders) and an aggregating *Web accessiblity evaluator* module. Through the *Query Interface*, and the query patterns described in this chapter, we envision that this architecture will facilitate on visualizing Web accessibility at a large scale. We believe that this will provide clues on how Web standards and accessibility recommendations should evolve in the future towards a universally accessible and usable Web.

CONCLUSION

In this chapter we have presented a semantic knowledge framework for Web accessibility. This framework supports the definition of Web graphs and their accessibility properties. Through a set of query patterns, we have described a way to mine Web graphs in order to understand how the Web can cope with end users' intrinsic and transient characteristics, such as disabilities, interactive devices, etc.

We are currently developing ongoing work to implement this framework within the context of the architecture proposed in the previous Section in cooperation with the Portuguese Web Archive (PWA, n.d.) and apply it to study the entire Portuguese Web (around 40 million Web pages). We believe that the set of query patterns presented in this chapter will help us to understand the shape of the Web in what respects to its Web accessibility properties. More specifically, it will allow us discovering which Web sites are more accessible, and to verify if Web sites created by non-experts have significant accessibility problems, in comparison to those created by experts.

KEY TERMS AND DEFINITIONS

Accessibility: The ability to access. Often tied to people with disabilities (e.g., total blindness), accessibility thrives to break the barriers to information access. We follow the strict sense of accessibility by embracing any situation where the ability to access information can be disrupted by device or even surrounding environment constraints.

Accessibility Guidelines: A set of best practices that must be followed by designers and developers when implementing software solutions (e.g., Web site) that will help on providing accessible information. By being guidelines, it should not be assumed that content is accessible just by following them.

Checkpoint: A concrete verification task that materializes a (part of a) guideline. Checkpoints can be fully automated if application technology provides corresponding support (e.g., verifying if all images have associated textual captions).

Metric: A quantification procedure based on several criteria. In the context of this Chapter, metrics quantify accessibility based on different accessibility checkpoints.

Universal Usability: A research field that studies the adequacy of user interfaces and information to all users, regardless of their characteristics, knowledge, or mean of interaction (Shneiderman, 2000).

Web Accessibility: The subfield of accessibility that is targeted to the specific technologies and architecture that compose the World Wide Web. This includes technologies such as HTML, CSS and JavaScript, as well as the HTTP protocol.

Web Graph: A formal representation of the Web's structure. Web pages are represented as the graph's nodes, whereas hyperlinks are represented as its arcs. By representing the Web as a graph, traditional graph analysis algorithms can be applied.

ABSTRACT

The World Wide Web serves as a huge, widely distributed, global information service center for news, advertisements, customer information, financial management, education, government, e-commerce and many others. The Web contains a rich and dynamic collection of hyperlink information. The Web page access and usage information provide rich sources for data mining. Web pages are classified based on the content and/or contextual information embedded in them. As the Web pages contain many irrelevant, infrequent, and stop words that reduce the performance of the classifier, selecting relevant representative features from the Web page is the essential preprocessing step. This provides secured accessing of the required information. The Web access and usage information can be mined to predict the authentication of the user accessing the Web page. This information may be used to personalize the information needed for the users and to preserve the privacy of the users by hiding the personal details. The issue lies in selecting the features which represent the Web pages and processing the details of the user needed the details. In this article we focus on the feature selection, issues in feature selections, and the most important feature selection techniques described and used by researchers.

INTRODUCTION

There are an estimated 15 to 30 billion pages available in the World Wide Web with millions of pages being added daily. Describing and organizing this vast amount of content is essential for realizing the web's full potential as an information resource. Automatic classification of web pages is needed for the following reasons. (a) Large amount of information available in the internet makes it difficult for the human experts to classify them manually (b) The amount of Expertise needed is high (c) Web pages are dynamic and volatile in nature (e) More time and effort are required for classification. (f) Same type of classification scheme may not be applied to all pages (g) More experts needed for classification. Web page classification techniques use concepts from many fields like Information filtering and retrieval, Artificial Intelligence, Text mining, Machine learning techniques and so on. Information filtering and retrieval techniques usually build either a thesauri or indices by analyzing a corpus of already classified texts with specific algorithms. When new text is to be classified, thesaurus and index are used to find the similarity with already existing classification scheme to be associated with this new text.

Until the late 1980s, the most effective approach to web page classification seemed to be that of manually by building classification systems by means of knowledge-engineering techniques, i.e. manually defining a set of logical rules that encode expert knowledge on how to classify web page documents under the given set of categories. In the 1990s this perspective has been overturn, and the machine learning paradigm to automated web page classification has emerged and definitely superseded the knowledge-engineering approach. Within the machine learning paradigm, a general inductive process automatically builds an automatic text classifier by "learning", from a set of previously classified web documents, the characteristics of the categories of interest. The advantages of this approach are accuracy comparable to human performance and a considerable savings in terms of expert manpower, since no intervention from either knowledge engineers or domain experts is needed. Currently web page categorization may be seen as the meeting point of machine learning and information retrieval. As Machine Learning aims to address larger, more complex tasks, the problem of focusing on the most relevant information in a potentially overwhelming quantity of data has become increasingly important. For instance, data mining of corporate or scientific records often involves dealing with both many features and many examples, and the internet and World Wide Web have put a huge volume of low-quality information at the easy access of a learning system. Similar issues arise in the personalization of filtering systems for information retrieval, electronic mail, net news.

The main objective of this chapter is to focus on the feature selection techniques, need for feature selection, their issues in web page classification, feature selection for privacy preserving data mining and the future trends in feature selection.

LITERATURE SURVEY

Rudy Setiono and Huan Liu (1997) proposed that Discretization can turn numeric attributes into discrete ones. χ^2 is a simple algorithm. Principal Component Analysis-compose a small number of new features. It is improved from simple methods such as equi-width and equal frequency intervals. For each and every attributes calculate the χ^2 value for each and every interval. Combine the lowest interval values while approximation.

Shounak Roychowdhury (2001) proposed a technique called granular computing for processing and expressing chunks of information called granules. It reduces hypothesis search space, to reduce storage. Fuzzy set based feature elimination techniques in which subset generation and subset evaluation are employed. For optimal feature selection brute force technique is employed.

Catherine Blake and Wander Pratt (2001) suggested the relationship between the features used to represent the text and the quality model. A comparison of association rules based on three different concepts: words, manually assigned keywords, automatically assigned concepts are made. Bidirectional association rules on concepts or keywords are useful than the words used. Each individual feature should be informative. The quality of features should be meaningful. The concepts and keywords also represent fewer 90% of the words used in the medical diagnosis.

Martin, Mario and Anil (2004) discuss the various algorithms of clustering and the issues of feature selection such as what attributes and data should be selected. Feature saliency should be maintained. EM algorithm and mixture based clustering are employed. Minimum message length-saliency of irrelevant features is reduced to zero. Methods based on variance (PCA) need not produce best features. The Filter and Wrapper approaches are also employed for feature classification.

Christoph, Nidal Zeidat, and Zhenghong Zhao (2004) proposed an algorithm called supervised clustering. The goal is to identify the class uniform clusters that have high probability densities.

Four algorithms have been suggested.

1. A greedy algorithm with random restart
2. SRIDHCR, that seeks for solutions by inserting and removing single objects from the current solution
3. SPAM (a variation of the clustering algorithm PAM),
4. An evolutionary computing algorithm named SCEC, and a fast medoid-based top-down splitting algorithm, named TDS. The four algorithms were evaluated using a benchmark consisting of four UCI machine learning data sets. Fitness function and Impurity and number of clusters are also taken into account.

Huang, McCullagh, Black (2004) used ReliefF as a feature mining technique that is sensitive to the definition of relevance. It is computationally expensive in handling large data sets. They proposed an optimization algorithm (Feature Selection via Supervised Model Construction) for data transformation and starter selection, and evaluate its effectiveness with C4.5. Frequency based encoding scheme is employed for transforming categorical data into numerical data. The number of instances sampled from the data set determines the selection of features. Experiments are performed on UCI Repository data set and concluded that their proposed supervised model outperforms the other models

WEB PAGE CLASSIFICATION

Web page classification, also known as web page categorization, is the process of assigning a web page to one or more predefined category labels. Classification is often posed as a supervised learning problem in which a set of labeled data is used to train a classifier which can be applied to label future examples. The general problem of web page classification can be divided into multiple sub-problems: subject classification, functional classification, sentiment classification, and other types of classification. Subject classification is concerned about the subject or topic of a web page. For example, Classifying whether a page is about “arts”, “business” or “sports” is an instance of subject classification. Functional classification cares about the role that the web page plays. For example, deciding a page to be a “personal homepage”, “course page” or “admission page” is an instance of functional classification. Sentiment classification focuses on the opinion that is presented in a web page, i.e., the author’s attitude about some particular topic. Based on the number of classes in the problem, classification can be divided into binary classification and multi-class classification, where binary classification categorizes instances into exactly one of two classes positive or negative) ; multi-class classification deals with more than two classes. Based on the number of classes that can be assigned to an instance, classification can be divided into single-label classification and multi-label classification. In single-label classification, one and only one class label is to be assigned to each instance, while in multi-label classification, more than one class can be assigned to an instance.

If a problem is multi-class, say four-class classification, it means four classes are involved.

Classification plays a vital role in many information management and retrieval tasks. In case of the Web, classification of page content is essential to focused crawling, to the assisted development of web directories, to topic-specific web link analysis, and to analysis of the topical structure of the Web. Web page classification can also help improve the quality of web search. Earlier surveys in web page classification typically lack a detailed discussion of the utilization of web specific features. In this article, we carefully examine the web-specific features and algorithms that have been explored and found to be useful for web page classification. The contributions of this article are:

- a detailed review of useful web-specific features for classification;
- various feature selection techniques used in classification; and,
- a discussion of future research directions.

WHAT IS FEATURE SELECTION?

Feature extraction or selection is one of the most important steps in pattern recognition or pattern classification, data mining, machine learning and so on. Generally speaking, only classification information is included sufficiently in the eigenvector, classifier can classify the classification rightly. However, it is difficult to measure classification information in all features. Data preprocessing is an indispensable step in effective data analysis. It prepares data for data mining and machine learning, which aim to turn data into business intelligence or knowledge. Feature selection is a preprocessing technique commonly used on high dimensional data. Feature selection studies how to select a subset or list of attributes or variables that are used to construct models describing data. Its purposes include reducing dimensionality, removing irrelevant and redundant features, reducing the amount of data needed for learning, improving algorithms' predictive accuracy, and increasing the constructed models' comprehensibility. Feature-selection methods are particularly welcome in interdisciplinary collaborations because the selected features retain the original meanings domain experts are familiar with. The rapid developments in computer science and engineering allow for data collection at an unprecedented speed and present new challenges to feature selection. Wide data sets, which have a huge number of features but relatively few instances, introduce a novel challenge to feature selection.

Need for Feature Selection

The web pages need 80% of the preprocessing work since the web pages have large amount of useless information. Data preprocessing describes any type of processing performed on raw data to prepare it for another processing procedure. Commonly used as a preliminary data mining practice, data preprocessing transforms the data into a format that will be more easily and effectively processed for the purpose of the user for example, in a neural network. There are a number of different tools and methods used for preprocessing, including: sampling, which selects a representative subset from a large population of data; transformation, which manipulates raw data to produce a single input; denoising, which removes noise from data; normalization, which organizes data for more efficient access; and feature extraction, which pulls out specified data that is significant in some particular context.

In a customer relationship management (CRM) context, data preprocessing is a component of Web mining. Web usage logs may be preprocessed to extract meaningful sets of data called user transactions, which consist of groups of URL references. User sessions may be tracked to identify the user, the Web sites requested and their order, and the length of time spent on each one. Once these have been pulled out of the raw data, they yield more useful information that can be put to the user's purposes, such as consumer research, marketing, or personalization.

Preprocessing makes it possible for complex homepages to be delivered lightning fast, and lets you significantly increase the number of pages served in an extremely cost-effective manner. The idea of preprocessing content for web pages grew out of necessity. Preprocessing can be achieved by the following ways:

A . Removing HTML tags:

HTML tags indicate the formats of web pages. For instance, the content within <title> and </title> pair is the title of a web page; the content enclosed by <table> and </table> pair is a table. These HTML tags may indicate the importance of their enclosed content and they can thus help weight their enclosed content. The tags themselves are removed after weighting their enclosed content.

B . Removing stop words:

Stop words are frequent words that carry little information, such as prepositions, pronouns, and conjunctions. They are removed by comparing the input text with a "stop list" of words.

C . Removing rare words:

Removing words whose number of occurrences in the text is less than a predefined threshold.

D . Performing word stemming:

Word stemming is done by grouping words that have the same stem or root, such as computer, compute, and computing. The Porter stemmer is a well-known algorithm for performing this task.

Issues in Feature selection

Feature extraction or selection is one of the most important steps in pattern recognition or pattern classification, data mining, machine learning and so on. But the increasing feature brings disadvantages for classification problem. On one hand, feature increased gives difficulties to calculate, because the more data occupy amount of memory space and computerization time, on the other hand, a lot of features include certainly many correlation factors respectively, which results to information repeat and waste. Therefore, we must take measures to decrease the feature dimension under not decreasing recognition effect; this is called the problems of feature optimum extraction or selection. On the other hand the number of features needs to be constrained to reduce noise and to limit the burden on system resources. The number of features needs to be constrained to reduce noise and to limit the burden on system resources.

Characteristics of Selected Features

The purposes of automated text categorization, features should be:

1. Relatively few in number
2. Moderate in frequency of assignment
3. Low in redundancy
4. Low in noise
5. Related in semantic scope to the classes to be assigned
6. Relatively unambiguous in meaning

DIMENSIONALITY REDUCTION BY FEATURE SELECTION

In statistics, dimension reduction is the process of reducing the number of random variables under consideration, and can be divided into feature selection and feature extraction. Feature selection, also known as variable selection, feature reduction, attribute selection or variable subset selection, is the technique, commonly used in machine learning, of selecting a subset of relevant features for building robust learning models. . By removing most irrelevant and redundant features from the data, feature selection helps improve the performance of learning models by:

- Alleviating the effect of the curse of dimensionality.
- Enhancing generalization capability.
- Speeding up learning process.
- Improving model interpretability.

Feature selection also helps people to acquire better understanding about their data by telling them that which are the important features and how they are related with each other. Feature selection selects a subset of the original feature space based on some criteria. Two broad approaches for feature selection have been presented in the literature: the wrapper approach and the filter approach. The wrapper approach employs a search through the space of feature subsets. It uses an estimated accuracy for a learning algorithm as the measure of goodness for a particular feature subset. Thus the feature selection is being "wrapped around" a learning algorithm. For example, for a neural network algorithm the wrapper approach selects an initial subset of features and measures the performance of the network; then it generates an "improved set of features" and measures the performance of the network. This process is repeated until it reaches a termination condition (either a minimal value of error or a number of iterations). While some wrapper based methods have encountered some success for classification tasks, they are often prohibitively expensive to run and can break down when a very large number of features are present. For the filter approach, feature selection is performed as a preprocessing step before applying machine learning. Thus the method of feature selection is independent to the learning algorithm. The filter algorithm does not incur the high computational cost and is commonly used in classification systems even in a very high feature space.

Feature extraction is a special form of dimensionality reduction.

When the input data to an algorithm is too large to be processed and it is suspected to be notoriously redundant (much data, but not much information) then the input data will be transformed into a reduced representation set of features (also named features vector). Transforming the input data into the set of features is called *features extraction*. If the features extracted are carefully chosen it is expected that the features set will extract the relevant information from the input data in order to perform the desired task using this reduced representation instead of the full size input. Feature extraction involves simplifying the amount of resources required to describe a large set of data accurately. When performing analysis of complex data one of the major problems stems from the number of variables involved. Analysis with a large number of variables generally requires a large amount of memory and computation power or a classification algorithm which overfits the training sample and generalizes poorly to new samples. Feature extraction is a general term for methods of constructing combinations of the variables to get around these problems while still describing the data with sufficient accuracy

Jun Yan, Benyu Zhang, Ning Liu, Shuicheng Yan, Qiansheng Cheng, Weiguo Fan, Qiang Yang, Wensi Xi, and Zheng Chen (2006) give an overview of the popularly used feature extraction and selection algorithms under a unified framework. They propose two novel dimensionality reduction algorithms based on the Orthogonal Centroid algorithm (OC). The first is an Incremental OC (IOC) algorithm for feature extraction. The second algorithm is an Orthogonal Centroid Feature Selection (OCFS) method which can provide optimal solutions according to the OC criterion. Both are designed under the same optimization criterion. Experiments on Reuters Corpus Volume-1 data set and some public large-scale text data sets indicate that the two algorithms are favorable in terms of their effectiveness and efficiency when compared with other state-of-the-art algorithms.

FEATURE SELECTION STEPS

Preprocessing of web pages is the first step for the web page classification problem. Web pages cannot be processed as such because of the size, content and nature of the web pages. Dimensionality reduction is an essential data preprocessing technique for large-scale and streaming data classification tasks. It can be used to improve both the efficiency and the effectiveness of classifiers. Traditional dimensionality reduction approaches fall into two categories: Feature Extraction and Feature Selection. Techniques in the feature extraction category are typically more effective than those in feature selection category. Feature extraction refers to the extraction from the various features of the web page such as Title, Meta and URL of the web page.

Feature selection is a process that selects a subset of original features. The optimality of a feature subset is measured by an evaluation criterion. A typical feature selection process consists of four basic steps namely, subset generation, subset evaluation, stopping criterion, and result validation. Subset generation produces candidate feature subsets for evaluation based on a certain search strategy. Each candidate subset is evaluated and compared with the previous best one according to a certain evaluation criterion. If the new subset turns out to be better, it replaces the previous best subset. The process of subset generation and evaluation is repeated until a given stopping criterion is satisfied.

FEATURE SELECTION TECHNIQUES

PCA

Principal Component Analysis (PCA) involves a mathematical procedure that transforms a large number of correlated variables into a smaller number of uncorrelated variables called principal components. The objectives of principal component analysis are to discover (or reduce) the dimensionality of the data set and identifies new meaningful underlying variables. The mathematical technique used in PCA is called eigen values. PCA is a classical statistical method that transforms the data to a new coordinate system such that the greatest variance by any projection of the data comes to lie on the first coordinate (called the first principal component), the second greatest variance on the second coordinate, and so on. PCA is theoretically the optimum transform for a given data in least square terms.

Principal Component Analysis is a feature selection technique that searches for c k-dimensional orthogonal vectors that can be used to represent the data, where c<=k. The original data are those projected into a smaller space, resulting in data compression. PCA can be used as a form of dimensionality reduction. The input data are normalized, so that each attribute falls within the same range. It helps to ensure that attributes with large domains do not dominate the smaller domains. It uses a special coordinate system that depends upon the cloud of points. Place the first axis in the direction of greater variance of the points to maximize the variance along that axis. The second axis is perpendicular to it. It is also a technique used to reduce multi dimensional data sets to lower dimensions for analysis.

PCA is a non-parametric analysis and independent of any hypothesis about data probability distribution. PCA compression and decompression are easy operations to perform given the model parameters. However, the latter two properties are regarded as weakness as well as strength, in that being non-parametric, no a-priori assumptions can be incorporated and that PCA compressions often incur loss of information. When used for the applications of clustering, the main limitation of PCA is that it does not consider class separability since it does not take into account the class label of the feature vector. PCA simply performs a coordinate rotation that aligns the transformed axes with the directions of maximum variance. There is no guarantee that the directions of maximum variance will contain good features for discrimination

Fei Wu,Yonglei Zhou and Changshui Zhang proposed a general iterative framework for relevant linear feature extraction that efficiently utilizes both the side information and unlabeled data to enhance gradually algorithms performance and robustness. Both good relevant feature extraction and reasonable similarity matrix estimation can be realized. They adopt Relevant Component Analysis (RCA) under this framework and get the derived Iterative Self-Enhanced Relevant Component Analysis (ISERCA) algorithm. The experimental results on several data sets show that ISERCA outperforms RCA. Side-information represents some equivalence constraint between pair of samples, indicating whether the two samples originate from the same but unknown category (positive constraint) or from two different categories (negative constraint). They use “labeled data” to denote the samples involved in the given side-information

Information Gain

Information Gain is a method that removes the less informative attributes, collecting the more informative ones for use in concept description analysis. It is a dimension based data analysis method. An arbitrary sample belongs to class C_i with the probability s/S where S is the total number of samples. The expected information gain is given by:

$$I(s_1,s_2,\ldots,s_m) = -\sum s/S \log s/S$$

and the gain is given by

$$\text{Gain} = I(s_1,s_2,\ldots,s_m) - E(A)$$

Information theoretic methods are also used to evaluate features: the mutual information between a relevant feature and the class labels should be high. Nonparametric methods can be used to compute mutual information involving continuous features.Although information gain is usually a good measure for deciding the relevance of an attribute, it is not perfect. A notable problem occurs when information gain is applied to attributes that can take on a large number of distinct values.

Mark Last and Oded, Maimon (2004) proposed an algorithm called Information theoretic algorithm that is based on minimal subset features. Information Network, is a tree like structure is formed by input features and the targeted classification. Unlike other decision-tree models, the information network uses the same input attribute across the nodes of a given layer (level). The input attributes are selected incrementally by the algorithm to maximize a global decrease in the conditional entropy of the target attribute. They employ the pre pruning approach: When no attribute causes a statistically significant decrease in the entropy, the network construction is stopped. More information implies higher accuracy of classification.

TF-IDF

Each document is represented in the term space, such that $d = \{w_1, w_2, \ldots, w_n\}$, where$w_i$, $i = 1, \ldots, n$, is the weight of term i in the document. The weight of a term could be simply calculated as the frequency of the term in that document ($w_i = tf_i$); i.e. how many times it appeared in the document. A more popular term weighting scheme is TF×IDF (Term Frequency ×Inverse Document Frequency), which takes into account the document frequency of a term (df $_i$), the nuwmber of documents in which the term appears. A typical inverse document frequency (idf) factor of this type is given by log(N/ df $_i$). Thus the TF×IDF weight of a term is w $_i$ = tf$_i$ × log(N/ df$_i$. In other words, terms that appear more frequently in a certain document but less frequently in other documents are given higher weights in that document, since it has higher correlation with that document than others. On the other hand, terms that appear frequently in all documents are penalized in all documents since they have less discrimination power.

Daniele Riboni(2005) conducted various experiments on a corpus of 8000 documents belonging to 10 Yahoo! categories, using Kernel Perceptron and Naive Bayes classifiers. They introduce a new method for representing linked pages using local information that makes hypertext categorization feasible for real-time applications. Experimental results show that the local words with a hyper textual one can improve classification performance.They tested five different text sources for web page representation namely:

BODY, META, TITLE, MT, the union of META and TITLE content and BMT, the union of BODY, META and TITLE content.

Alexandros Kalousis, Julien Prados, Melanie Hilario (2005) suggested that study is an attempt to fill the gap by quantifying the sensitivity of feature selection algorithms to variations in the training set. The authors assess the stability of feature selection algorithms based on the stability of the feature preferences that they express in the form of weights scores, ranks or a selected feature subset. They examine a number of measures to quantify the stability of feature preferences and propose an empirical way to estimate them.

Chi-Square (CHI)

In probability theory and statistics, the chi-square distribution (also chi-squared or χ^2 distribution) is one of the most widely used theoretical probability distributions in inferential statistics, i.e. in statistical significance tests. It is useful because, under reasonable assumptions, easily calculated quantities can be proven to have distributions that approximate to the chi-square distribution if the null hypothesis is true. The chi-square distribution has one parameter: *k* - a positive integer that specifies the number of degrees of freedom (i.e. the number of X_i). The chi-square distribution is a special case of the gamma distribution. The best-known situations in which the chi-square distribution is used are the common chi-square tests for goodness of fit of an observed distribution to a theoretical one, and of the independence of two criteria of classification of qualitative data. However, many other statistical tests lead to a use of this distribution. Chi-square measures the lack of independence between a term t and a category c_i and can defined as

$$x^2\left(t, c_i\right) = \frac{N\left[P\left(t, c_i\right)P\left(\bar{t}, \overline{c_i}\right) - P\left(t, \overline{c_i}\right)P\left(\bar{t}, c_i\right)\right]^2}{P\left(t\right)P\left(\bar{t}\right)P\left(c_i\right)P\left(\overline{c_i}\right)}$$

Hongjun Lu, Sam Yuan Sung and Ying Lu (1996) propose Conflict analysis that is finding a set of attributes having perfect association with the class labels contingency table analysis is used with the nominal variables –the variables whose values are from an unordered set used chi square statistics.

Correlation coefficient (CC)

Correlation is a measure to identify the relationship between the attributes. For that purpose, correlation coefficients are introduced. The correlation coefficient is a number between -1 and 1 which measures the degree to which two variables are linearly related. If there is perfect linear relationship with positive slope between the two variables, we have a correlation coefficient of 1; if there is positive correlation, whenever one variable has a high (low) value, so does the other. If there is a perfect linear relationship with negative slope between the two variables, we have a correlation coefficient of -1; if there is negative correlation, whenever one variable has a high (low) value; the other has a low (high) value. A correlation coefficient of 0 means that there is no linear relationship between the variables.

Wen-Zhou Chen and Lei Li (2004) proposed a model of Correlation based Modified SVM, which ranks the features according to the correlation measures. Forward selection search with correlation based method to form a feature subset, labeled training examples each with a feature vector and a class are used.

Correlation coefficient of a word t with a category c_i and can be defined as

$$CC\left(t,c_i\right)=\frac{\sqrt{N}\left[P\left(t,c_i\right)P\left(\bar{t},\overline{c_i}\right)-P\left(t,\overline{c_i}\right)P\left(\bar{t},c_i\right)\right]}{\sqrt{P\left(t\right)P\left(\bar{t}\right)P\left(c_i\right)P\left(\overline{c_i}\right)}}$$

Odds ratio (OR)

The odds ratio is one of a range of statistics used to assess the risk of a particular outcome if a certain factor (or exposure) is present. The odds ratio is a relative measure of risk, telling us how much more likely it is that someone who is exposed to the factor under study will develop the outcome as compared to someone who is not exposed. Odds are a way of presenting probabilities. The odds of an event happening is the probability that the event will happen divided by the probability that the event will not happen. It is a measure used for selecting terms for relevance feedback. The basic idea is that the distribution of features on the relevant documents is different from the distribution of features on the non-relevant documents. It is defined as follows:

$$OR\left(t,c_i\right)=\log\frac{P\left(t,\middle|c_i\right)\left[1-P\left(t\middle|\overline{c_i}\right)\right]}{\left[1-PP\left(t,\middle|c_i\right)\right]P\left(t\middle|\overline{c_i}\right)}$$

Filters and Wrappers

The filter approaches evaluate the relevance of each feature (subset) using the data set alone, regardless of the subsequent learning algorithm. The filter model relies on general characteristics of the training dataset to select some features without involving any learning algorithm. The wrapper model requires one predetermined learning algorithm in feature selection and uses its performance to evaluate and determine which features are selected. It invokes the learning algorithm to evaluate the quality of each feature (subset). Specifically, a learning algorithm (e.g., a nearest neighbor classifier, a decision tree, a naive Bayes method) is run on a feature subset and the feature subset is assessed by some estimate of the classification accuracy. Wrappers are usually more computationally demanding, but they can be superior in accuracy when compared with filters, which ignore the properties of the learning task at hand. Wrapper models tend to find features better suited to the predetermined learning algorithm resulting in superior learning performance, but it is also computationally expensive compared to the filter model.

Huan Liu and Lei Yu proposed that feature selection algorithms for classification and clustering, groups and compares different algorithms with a categorizing framework based on search strategies, evaluation criteria, and data mining tasks, reveals unattempted combinations, and provides guidelines in selecting feature selection algorithms. With the categorizing framework, an integrated system for intelligent feature selection is built up. For employing feature selection, wrapper, filter and hybrid model are adopted.

Elı´as, Elena Montane´ s, Irene Dı´az, Jose´ Ranilla, and Ricardo Mones (2005) suggested that to select the relevant features by a family of linear filtering approaches. The feature selection approaches are bag of words representation, filter and wrapper approaches, term frequency, document frequency, inverted document frequency and the Information Gain indicates the presence of word in the category or not. The distribution of documents over the categories is considered by introducing the concept of canonical or unconditional rule which says that any document belongs to the category. This rule is used as a reference for the rest of rules of the same category. SVM classifier is employed with Reuters 21578 collections as the experimental data.

Decision Tree Based Feature Selection

The basic decision tree induction is a greedy algorithm that constructs decision trees in a top-down recursive divide and conquer manner. Nodes in the decision tree involve testing a particular attribute. The test at a particular node compares the attribute values with a constant.

A decision tree can be constructed top-down using the information gain in the following way:

1. begin at the root node
2. determine the attribute with the highest information gain which is not used in an ancestor node
3. add a child node for each possible value of that attribute
4. attach all examples to the child node where the attribute values of the examples are identical to the attribute value attached to the node
5. if all examples attached to the child node can be classified uniquely add that classification to that node and mark it as leaf node
6. go back to step two if there is at least one more unused attribute left, otherwise add the classification of most of the examples attached to the child node

Philip Laird Ronald Saul (1994) proposed that each object is represented in the form of vector of attribute values. Genetic based algorithm includes decision trees, feed forward neural networks and Bayesian classifiers. Value-class pair(x,C) is generated. Based on the value-class pair decision tree is constructed. At each node in the tree, a feature is tested for inclusion in two or more sets or in ranges. Minimum message length (MML) is used to determine the mutual information gain. Fringe technique is employed to identify the identical sub trees and the determination of the root.

Heuristic Search Trees

The predominant state-space planning methods in artificial intelligence are collectively known as heuristic search. Heuristic search is not concerned with changing the approximate, or “heuristic,” value function, but only with making improved action selections given the current value function. In other words, heuristic search is planning as part of a policy computation. In heuristic search, for each state encountered, a large tree of possible continuations is considered. The approximate value function is applied to the leaf nodes and then backed up toward the current state at the root. The backing up stops at the state-action nodes for the current state. Once the backed-up values of these nodes are computed, the best of them is chosen as the current action, and then all backed-up values are discarded. In conventional heuristic search no effort is made to save the backed-up values by changing the approximate value function. In fact, the value function is generally designed by people and never changed as a result of search.

In conventional heuristic search, this process computes backed-up values of the possible actions, but does not attempt to save them. Thus, heuristic search can be viewed as an extension of the idea of a greedy policy beyond a single step. Search methods traverse the attribute space to find a good subset. Quality is measured by the chosen attribute subsets. Subsets that have been cached are evaluated.

Pat Langley (1994) proposes that the Heuristics search through a space of feature set. Search Space specifies a subset of original feature. First determine the starting point and next the direction in which they are applied .It includes forward selection & backward elimination greedy approach (BFS)

Clustering with Tree Representation

Clustering is the classification of objects into different groups, or more precisely, the partitioning of a data set into subsets (clusters), so that the data in each subset (ideally) share some common trait - often proximity according to some defined distance measure. Data clustering is a common technique for statistical data analysis, which is used in many fields, including machine learning, data mining, pattern recognition, image analysis and bioinformatics. Data clustering algorithms can be hierarchical or partitional. Hierarchical algorithms find successive clusters using previously established clusters, whereas partitional algorithms determine all clusters at once. Hierarchical algorithms can be agglomerative ("bottom-up") or divisive ("top-down"). Agglomerative algorithms begin with each element as a separate cluster and merge them into successively larger clusters. Divisive algorithms begin with the whole set and proceed to divide it into successively smaller clusters. Two-way clustering, co-clustering or biclustering are clustering methods where not only the objects are clustered but also the features of the objects, i.e., if the data is represented in a data matrix, the rows and columns are clustered simultaneously

An algorithm for feature selection that clusters attributes using a special metric and, generates clusters that are placed in a cluster tree. Clustering is obtained by extracting those clusters that are situated at a given height in this tree.

Richard Butterworth, Gregory Piatetsky-Shapiro and Dan (2005) devised an algorithm for feature selection that clusters attributes using a special metric and then makes use of the dendrogram of the resulting cluster hierarchy to choose the most relevant attributes. The main interest of our technique resides in the improved understanding of the structure of the analyzed data and of the relative importance of the attributes for the selection process. Hierarchical algorithms generate clusters that are placed in a cluster tree, which is commonly known as a dendrogram. Clusters are obtained by extracting those clusters that are situated at a given height in this tree.

Hierarchical Trees

A hierarchical method creates a hierarchical decomposition of the given set of objects. A hierarchical method can be classified as agglomerative or divisive approach which is based on how the hierarchical decomposition is formed. The agglomerative approach is a bottom-up approach. The divisive approach is a top-down approach.

Shou-Bin Dong (2004) proposed a technique of hierarchical classification of web content based on the combination of both textual and visual features. Images can be ignored during classification. Combination of multiple classifiers is employed. The most widely used approach typically combines the classifier outputs directly by means of simple combining rules or functions. It relates to techniques like majority vote, threshold voting, averaged Bayes classifier, different linear combinations of a posteriori probabilities, maximum and minimum rules, product rule. Page, summary, title, image related text are also taken into account.

Suresh, Jitender, Vijay and Heyeri Sever (1996) use four feature selection algorithms-all the algorithms start with the same feature space but the heuristic used for pruning is different. The objective is to find a small amount of features that are sufficient and necessary for describing the feature space

1. **Best fit SBS:** Start with all the features and the features are removed one at a time
2. **Hybrid Heuristic SBS:** The current node is considered as the root node. The root nodes are expanded in such a way that the successors have one less condition attributes than its predecessors
3. **Alternating heuristic SBS:** The current node is assigned as the root node. Alternately BFS and first fit can be employed to find the next node of detail.
4. **k-level best SBS:** It divides the search space into k-groups starting from the root node to the leaf node. The last stage contains less than k-levels.

FUTURE TRENDS IN FEATURE SELECTION APPROACH

Hybrid Feature Selection

Hybrid feature selection combines different feature selection algorithms. It took the best characteristics of each and every algorithm and combines them effectively. Now –a-days the researchers used to combine the multiple feature selection algorithms for classification.

Yi Lu Murphey and Hong Guo (2000) proposed a model called hybrid feature selection algorithm using three different statistical measurements such as class pair-wised distance, linear separability, and overlapped feature histogram. They applied Bayes EM algorithm to select a sub-optimal set. The hybrid feature selection algorithm can be used as a preprocessing in a classification system and it is independent of the classifier to be used in the subsequence stage.

Hwanjo Yu, Kevin Chen-Chuan Chang and Jiawei Han (2002) propose a model that eliminates the need for negative training data and they concluded that the classification accuracy is increased by using two learners.

Sampling Technique and Correlation

Sampling is a reduction technique as it allows a large data set to be represented as small samples of data. The samples are thus correlated and the results are validated. Sampling is that part of statistical practice concerned with the selection of individual observations intended to yield some knowledge about a population of concern, especially for the purposes of statistical inference. Each observation measures one or more properties (weight, location, etc.) of an observable entity enumerated to distinguish objects or individuals.

Sriharsha Veeramachaneni Paolo Avesani (2004) proposed a technique of sampling the feature values with the ultimate goal of choosing between alternative candidate features with minimum sampling cost. Their heuristic algorithm is based on extracting candidate features in a region of the instance space. An experimental evaluation on a standard database shows that it is possible outperform a random sub sampling policy in terms of the accuracy in feature selection. The basic idea is to prescribe an iterative policy that chooses the next instance on which the candidate features are to be probed.

PRIVACY PRESERVING DATA MINING USING FEATURE SELECTION TECHNIQUES

Data mining is usually performed for applications not having personal details like weather forecasting, GPSS, etc. But data mining for banking, e-commerce, mobile and the like applications involve databases with personal details. Here the security aspects have to be taken into account while retrieving the features used to find the required web page by the user. One way to achieve this is by using a multilevel authentication system. The user giving the query must be an authenticated user to pose that query. Another way is to distort the data by inserting noise so that no one can access the personal details only the results or prediction can be shown. Yet another way is encrypt the information stored in the database so that if more than one person/company involved in the data mining, no one can get the other person/company details. Data mining can also be used to detect susceptible queries that intend to retrieve the personal information and also can be used to detect the person/program who did it. All the above feature selection techniques can be used to deal the security issues and to find the best features.

CONCLUSION

In this chapter we focus on various feature selection methods and how they are used by many researchers for selecting optimal feature set for web page classification problem. We mainly concentrate on the various ways a particular method is used for the purpose rather than giving references that solve the problem in the same way. This article may be incomplete in the aspect that it does not refer all the papers in the feature selection area but this is a useful research work for researchers who do research in the web page representation and web page classification areas.

KEY TERMS

Feature Extraction: Feature extraction is the preceding step to feature selection. It includes the collection of features from the Web pages. It can be done using any of the feature extraction techniques. All the collected features during the feature extraction phase need not be relevant.

Feature Selection: Feature selection is a process of selecting the relevant features needed for classification purposes. Feature selection is the most important step because the selected features determine the classification accuracy. Feature selection is a preprocessing technique commonly used on high dimensional data. Feature selection studies how to select a subset or list of attributes or variables that are used to construct models describing data. Its purposes include reducing dimensionality, removing irrelevant and redundant features, reducing the amount of data needed for learning, improving algorithms' predictive accuracy, and increasing the constructed models' comprehensibility.

HTML Structure: HTML refers to Hypertext Markup Language. It is used for the design of Web pages. Most of the Web pages contain html tags enclosed.

Machine Learning: Machine learning usually refers to the changes in systems that perform tasks associated with artificial intelligence. Such tasks involve recognition, diagnosis, planning, robot control and prediction etc.It is a technique commonly used for automatic classification of Web pages. It includes both the training phase and the testing phase. The training phase is used to learn from examples. Based on the learning the classifier classifies during the testing phase. Machine learning has a wide spectrum of applications including natural language processing, syntactic pattern recognition, search engines, medical diagnosis, bioinformatics, detecting credit card fraud, stock market analysis, classifying DNA sequences, speech and handwriting recognition, object recognition in computer vision, game playing and robot locomotion

Preprocessing: Preprocessing is the process of removing unnecessary information before the classification of Web pages. It includes removing common words, rare words, removing HTML tags and stemming.

Web Page Classification: Web page classification, also known as Web page categorization, may be defined as the task of determining whether a Web page belongs to a category or categories. It can be done by considering the various features like URL, head, title and the body contents of the Web page.

World Wide Web: The World Wide Web (commonly shortened to the Web) is a system of interlinked hypertext documents accessed via the Internet. With a Web browser, a user views Web pages that may contain text, images, videos, and other multimedia and navigates between them using hyperlinks. The World Wide Web is also called as net of networks. It contains a large amount of information needed for the Internet browsers. Boundless amount of information can be downloaded at any point of time.

Chapter 5.16
Implementing Collaborative Problem-Based Learning with Web 2.0

Steven C. Mills
The University Center of Southern Oklahoma, USA

ABSTRACT

Educators face the challenge of keeping classroom learning relevant for a generation of students who have never known life without computers, cell phones, and email. With Web 2.0 technologies educators can easily mediate student-centered learning experiences that engage students collaboratively in problem-solving and critical thinking. This chapter describes how Web 2.0 technologies can supply communication tools and information resources that facilitate the application of a robust set of instructional methodologies in the K-12 classroom. When the pedagogical features of Web 2.0 technologies are used with problem-solving methodologies, teachers can create powerful student-centered learning experiences for educating students for the 21st century.

INTRODUCTION

An 8th grade science teacher, Ms. S, retrieves her MP3 player from the computer-connected cradle where it's spent the night scanning the 17 podcasts she subscribes to. Having detected three new programs, the computer downloaded the files and copied them to the handheld. En route to work, Ms. S inserts the device into her dash-mounted cradle and reviews the podcasts, selecting a colleague's classroom presentation on global warming and a NASA conference lecture about interstellar space travel…

Meanwhile, social studies teacher Ms. L scans through sites tagged genetics in the school's social bookmark service. Her students may need quick access to them as they discuss genetic engineering current events during class…All assignments in Ms. L's class are turned in via blogs because she finds that their conversational nature encourages students to think and write in more depth than traditional formal essays or short answer assignments. Another advantage of receiving assignments in blog format is that both she and her students can subscribe, which means all of the students' blogs appear in her aggregator, and students can reap the benefits of seeing each other's work.

DOI: 10.4018/978-1-60566-120-9.ch024

A few doors down the hall, veteran English teacher, Mr. P, is reviewing a new batch of student wikis. In an effort to help the students become better communicators, he never provides study guides for tests, instead relying on students to construct their own study resources using their team wikis. He rewards teams that create the most useful/popular study guides. Mr. P uses a wiki tool installed on the school's network…

From *A Day in the Life of Web 2.0* by David Warlick

Over the past decade and a half since the creation of the Internet and the World Wide Web the use of information technology has significantly increased in K-12 classrooms. As the Web continues to evolve, new Internet and Web technologies become facts of life for today's students. And as David Warlick (2006) indicates in *A Day in the Life of Web 2.0*, teachers are using Web 2.0 technologies in K-12 classrooms because it is compatible with the technology many students use on a daily basis through popular websites such as MySpace, Wikipedia and Flikr.

According to Lee Rainie, Director of the Pew Internet and American Life project, "an American teen is more likely than her parents to own a digital music player like an iPod, to have posted writing, pictures or video on the Internet, to have created a blog or profile on a social networking website like MySpace, to have downloaded digital content such as songs, games, movies, or software, to have shared a remix or 'mashup' creation with friends, and to have snapped a photo or video with a cell phone." (Rainie, 2006). Because of this daily high-level interaction that youth have with technology, educators face the challenge of keeping classroom learning relevant for a generation of students who have never known life without computers, cell phones, and email. Baird and Fisher (2005-2006) note that "neomillennial students expect interactive, engaging content and course material that motivates them to learn through challenging pedagogy." Thus, the bar has been raised seemingly beyond the technological expertise of many educators for providing learning experiences that keep today's students interested and engaged.

The good news for educators is that the latest expression of the World Wide Web, known as Web 2.0, provides online information resources and communication technologies that are easier to use and simpler to implement, requiring far less technological expertise than the preceding generation of Internet applications. With Web 2.0 it is far easier for educators to mediate student-centered learning experiences utilizing the pedagogical features of these new technologies. For example, the social networking capabilities of Web 2.0 familiar to most students can promote student engagement in learning because students actively participate in constructing a learning landscape based on social interactions and information exchanges with peers (Baird & Fisher, 2005-2006).

Web 2.0 is a term used to describe Web technologies used to harness collective intelligence, provide interfaces and services across multiple devices, and enhance collaboration. Although the term, Web 2.0, suggests a new version or generation of the World Wide Web, in reality it refers to a re-visioning of the Web—what Downes (2005) characterizes not as a technological revolution but as a social revolution. Thus, Web 2.0 relates to new ways to use the Web rather than an update to the technical specifications of the Web. According to Downes, Web 2.0 represents a shift from an information-consumption medium to an information-creation platform: "In a nutshell, what was happening was that the Web was shifting from being a medium, in which information was transmitted and consumed, into being a platform, in which content was created, shared, remixed, repurposed, and passed along. And what people were doing with the Web was not merely reading books, listening to the radio or watching TV, but having a conversation, with a vocabulary consisting not just of words but of images, video, multimedia and whatever they could get their hands on."

Perhaps the most well-known example of Web 2.0 is a blog. Blogs permit writers, known as a bloggers, to post commentary and visitors to leave responses. Other examples of Web 2.0 applications are wikis, podcasts, Web feeds, social bookmarking, and social networking. Interactive online games and virtual worlds could also be considered Web 2.0 applications. While the label "Web 2.0" may imply a more advanced use of technology to deploy the Internet, what is important to this discussion is the pedagogical features of Web 2.0 that can be exploited for relevant and effective classroom instruction. Web 2.0 provides the affordance of collaborative information discovery that can be converted into instructional methodologies (Alexander, 2006) that can scaffold student learning in K-12 classrooms.

The International Society for Technology in Education's (2007) release of the National Educational Technology Standards for Students (NETS-S) indicates that to learn effectively and live productively in an increasingly digital world, students should know and be able to use technology for creativity and innovation, communication and collaboration, research and information fluency, and critical thinking, problem-solving, and decision-making. For K-12 classrooms to address these standards, instructional approaches must facilitate active, resource-rich, student-centered learning environments that help students learn to think critically, analyze and synthesize information to solve technical, social, economic, political, and scientific problems, and work productively in groups (Mills, 2006). Classroom learning activities should focus on rich, multidisciplinary learning tasks that address complex sets of learning objectives.

One way for K-12 schools and classrooms to address the NETS-S is by deploying Web 2.0 technology in the classroom. Web 2.0 is useful for implementing complex learning objectives because of its ability to combine technology with collaboration to facilitate functional communication with professionals, subject experts and other students who have Internet access. Using Web 2.0 technologies, information can be manipulated and meshed to generate knowledge for creating new solutions, solving problems or making decisions because Web 2.0 permits substantive information exchanges and collaborations among peers and with subject-matter experts outside of the classroom.

Some Web 2.0 technologies that are commonly used by today's students that have broad subject-matter applications include blogs, wikis, Web feeds, podcasts, and Web conferencing. For example, blogs and wikis can enhance writing experiences. With a school or classroom blog students can receive editing advice and content corrections from peers. Wiki software can be used to enhance research and writing objectives by enabling students to add a section of research to a document being created by a group or class. The live editing of the document permitted by the wiki allows for writing and research revisions through peer editing. Thus, students strengthen writing skills and sharpen research skills because they are engaged in learning through a collaborative communication process.

With RSS or Web feeds, teachers and administrators can communicate news, events, and activities to students and parents. For example, school administrators can send announcements about school events to parents and teachers can send homework assignments and other classroom reminders to students. Podcasts can be used in the same way as RSS feeds to mass communicate with students and parents. With podcasts, teachers and administrators use pre-recorded audio or video messages. Teachers can also use podcasts to record classroom instruction to create an archive for students to review for exams or for absent students to access and use for make-up work.

Web 2.0 has applied the complex technologies of videoconferencing to the personal computer. Communication at a distance that used to require expensive decoding equipment can now be performed with webconferencing software via most personal computer connections to the Internet. With webconferencing guest speakers can be brought into the local classroom from anywhere in the world there is an Internet connection. Students can speak with scientists and other content experts or even students from classes in different countries.

The vast resources of data and information on the Internet supply tools and resources that permit application of a broader and more powerful set of instructional methodologies in the classroom. Using Web 2.0 technologies to support teaching and learning makes it possible to use powerful methodologies such as cases, projects, and problems that are relevant and representative of real-world tasks. However, using Web 2.0 to implement these more powerful instructional methodologies requires teachers to create learning experiences that align with the classroom curriculum.

Because Web 2.0 technologies best support instructional methodologies that employ collaborative and authentic learning experiences, implementing Web 2.0 technologies in the K-12 classroom will generally take the form of project- or problem-based learning (PBL). Therefore, the following sections of this chapter will first establish a framework for PBL that demonstrates its effective implementation when embedded with Web 2.0 capabilities and then will describe some Web 2.0 technologies that are effective for developing PBL experiences.

LEARNING THEORY, PROBLEM-BASED LEARNING, AND WEB 2.0

Cognitive learning theories influence most modern pedagogy. Cognitive learning theories place more emphasis on factors that are internal to the learner than behavioral theories, which place more emphasis on factors within the environment (Smith & Ragan, 1999). Information processing theory is a cognitive learning theory that has provided an important contribution to the field of instructional design and development (Smith & Ragan) as well as to learning and developmental psychology (Bransford, Brown, & Cocking, 2000).

Information processing theory hypothesizes a set of structures in the brain that work much like a computer. For learning to occur, a series of transformations of information takes place in or through these structures. Like a computer, the human brain receives information into working memory, performs operations on the information to change its form and content, and stores it in long-term memory, then locates it and generates responses to it.

Information processing theory suggests that there is a two-way flow of information as we try to make sense of the world around us (Huitt, 2003). We use information that we gather through the senses and information we have stored in memory in a dynamic process to construct meaning about our environment and our relations to it. Information processing theory defines the learning process as based on integrating or assimilating information into long-term memory in a meaningful way that includes gathering and representing information, called *encoding*, storing information, called *retention*, and then getting at the information when needed, called *retrieval*.

Transfer is an important process for acquiring a deep or meaningful understanding of learned information. Transfer of learning occurs when a learner unconsciously or deliberately applies knowledge or skills associated with one task to the completion of another task. In one sense, the purpose of learning is to transfer knowledge and skills from one situation, context, or domain to another. Transfer of learning can occur along a continuum of varying degrees of difficulty where transfer of certain knowledge or skills can be developed to a high-level of automaticity while transfer of other knowledge or skills requires conscious, deliberate efforts.

PBL is an instructional methodology that is fully compatible with information processing theory. With PBL students construct an individual understanding of the problem and then develop and present a solution. PBL is well-suited to encoding and transfer because it situates learning in real-world problems and develops solutions through collaborative processes.

Web 2.0 technologies can be used to support problem-based learning in the K-12 classroom. For example, Web 2.0 applications can provide information tools and resources that can be deployed to simulate real-world problems by providing both content and context for a problem. Using Web 2.0 technologies, the Web can be explored to identify and acquire the information necessary to understand the problem and students can communicate with outside experts or peers to develop solutions to the problem.

With PBL the teacher guides students through a problem-solving process. Students may first reason through the problem and apply knowledge they already have to the problem. This elaboration of prior knowledge helps students understand what information they need to acquire to better understand and resolve the problem. As students begin to research and acquire information about the problem and reach possible solutions, they develop the information literacy skills they need to become self-directed learners.

Learning Strategies and Problem-Based Learning

Many learning theorists believe that working memory has limited capabilities; therefore, it is necessary for learners to employ strategies to regulate their learning when performing learning tasks. For example, information processing theory assumes that that a control mechanism is required to oversee the encoding, transformation, processing, storage, retrieval and utilization of information because of mental constraints on the amount of information that can be processed and the automaticity of the task. Therefore, not all of the processing capacity of the system is available because an executive function that oversees this process will use up some of this capability when one is learning a new task or is confronted with a new environment.

Learning, then, is facilitated by executive functions called cognitive and metacognitive strategies. Cognitive strategies include mental activities such as acquiring, selecting and organizing information, rehearsing material to be learned, relating new material to information in memory, and retrieving and retaining different kinds of knowledge. Metacognitive strategies deal with strategic learning or "learning to learn." Some common metacognitive strategies include connecting new information to former knowledge, deliberate selection of cognitive strategies, and planning, monitoring, and evaluating cognitive processes.

Problem-solving and related research activities can provide opportunities for developing the cognitive and metacognitive strategies that facilitate learning. Students can learn how to learn by developing a repertoire of cognitive or thinking processes that can be applied to solve problems. As students perform problem-solving activities, teachers can focus student attention not only on solutions (products) but also on how tasks are accomplished (processes).

When using problem-solving activities in the K-12 classroom, learning strategies can be embedded in the instructional content and procedures so that these process and product goals are accomplished and evaluated. Web 2.0 can provide technology tools teachers can use to mediate instruction and instructional procedures effectively. Web 2.0 technologies such as social bookmarks, blogs, and wiki can be embedded into PBL experiences to scaffold the cognitive and metacognitive strategies that result in potentially powerful, high-impact learning experiences.

Collaboration and Problem-Based Learning

PBL focuses on challenging problems or tasks that can improve higher-order thinking skills. Because PBL is often used to perform complex tasks or solve ill-structured or ill-defined problems, a student working independently may not possess the knowledge, skills, or time to accomplish the task. Therefore, PBL can be used to help students learn to work together collaboratively and cooperatively.

Collaborative learning refers to a variety of educational approaches that involve shared intellectual efforts by peers or experts. Collaborative learning generates dialog and interaction among peers or communities of peers and experts for the purpose of constructing collective knowledge or shared understanding about a concept, case, or problem. Schrage (1990) defined collaboration as "two or more individuals with complementary skills interacting to create a shared understanding" (p. 40). With collaborative learning, peers are responsible for one another's learning as well as their own learning. Peers work in groups of two or more to search for a mutual understanding, solution, or meaning and to create a product of their shared learning experience.

Collaborative learning activities can range from classroom discussions that may include short lectures to participation on research teams. Generally, collaborative learning activities are designed to encourage interaction among students and promote consensus-building in reaching a shared solution. Through collaboration and cooperation, peers investigate subject matter at varying levels. Collaborative learning builds student awareness of different perspectives. By justifying and defending their ideas to peers, students build deeper knowledge and understanding of a topic. Collaborative learning is especially appropriate for complex and ill-defined problems because the construction of complex knowledge seems to be facilitated by collaborative processes (Feltovitch, Spiro, Coulson, & Feltovich, 1996). Collaborative problem-solving can be supported with Web 2.0 communication tools that facilitate the exchange of ideas among participants.

Group learning can build collective knowledge based on shared problem-solving, interpersonal feedback, and social support and encouragement. Small groups can work together; collaboration and teamwork can be facilitative and can provide scaffolding for the construction of knowledge as well as enhance student satisfaction and learning (Doran, 2001). To form and use groups effectively for collaborative learning, teachers should employ a number of techniques including incorporating team-building activities at the beginning of the year, establishing a feedback process, requiring groups to report progress to the teacher online or face-to-face, evaluating group experiences and providing evaluation or assessment information to the teacher, and employing multiple instructional strategies with group work (Doran).

Collaborative problem-solving using Web 2.0 technologies may utilize teams of students within the same classroom or in classrooms in multiple locations. Therefore, forming effective groups is an important aspect of using online communication to increase student participation in learning and to develop a learning community in the classroom. Online communication tools can be used effectively for collaborative problem-solving, even among students in the same classroom working in small groups because students can access information resources, experts, or peers anywhere in the world. Wikis or blogs may work best for teams of students formed within a classroom while webconferencing, podcasts, and social networking may work best with distant participants.

Collaborative problem-solving in the K-12 classroom can maximize learning by organizing instruction according to the abilities and learning needs of students. When students work in groups, they bring different abilities and expertise to the learning dynamic. Group learning can promote academic achievement by allowing students to encourage each other, ask questions of one another, require each other to justify opinions and reasoning, and reflect upon their collective knowledge, (Brown, A. & Palincsar, A., 1989; Cohen, 1994; Johnson & Johnson, 1994). Collaborative learning is easy and inexpensive to implement and can promote improved behavior, attendance and positive attitudes about school (Slavin, 1987).

Having students work in groups encourages discussion and develops social skills useful for a professional working environment for which they are training. Group collaboration takes advantage of learner-learner interactions rather than learner-content interactions for learning. Small groups working on a project learn the team-building skills and goal-setting strategies needed to be productive in the workplace. Collaborative learning activities can increase students' satisfaction with the learning process and can decrease the time required by the teacher for administering and structuring a course, program, or other unit of instruction.

Collaborative learning is about building learning communities in the classroom, and learning communities can provide an organizing structure and delivery system for the practice of collaborative learning. Learning communities frequently provide more time and space for collaborative learning and other more complicated educational approaches. K-12 classrooms can provide a sense of community by promoting and supporting collaborative learning.

From its beginning the Internet and its associated applications and services have been substantially social and Web 2.0 technologies have served to increase the extent of these social capabilities to make the Web especially connective (Alexander, 2006). According to Alexander it is the affordance of collaborative information discovery that makes Web 2.0 technologies useful for education and instruction. Web 2.0 technologies such as social networking, media sharing, podcasting, and webcasting make it possible to transform classrooms into virtual learning communities by connecting students with peers, experts, and resources beyond the classroom. K-12 classrooms can create collective knowledge through the discoveries of students sharing information, interests and learning objectives via the Internet. This collective knowledge can even transcend a single classroom and a single school year through collaborative, problem-solving activities that allow students to build upon the knowledge and discoveries of predecessors.

WEB 2.0 TECHNOLGIES FOR PROBLEM-BASED LEARNING

Problem-solving consists of moving from an initial, undesired situation to a desired goal and so problem-solving is a process of planning and executing a set or series of steps to reach the goal (Moursund, 1999). There are numerous Web 2.0 applications and services that are available to support collaborative information problem-solving that can engage students in meaningful, challenging, and motivating inquiry and critical thinking.

In this section we will consider several Web 2.0 technologies that have particular application to instruction, especially in developing collaborative PBL experiences for the K-12 classroom. This discussion is not meant to be a comprehensive list of Web 2.0 technologies but rather a substantive discussion of Web 2.0 technologies that are most familiar to today's students and have features and capabilities that are relatively simple to use and to embed in PBL experiences.

RSS and Aggregators

RSS stands for Rich Site Summary or Really Simple Syndication. RSS is a standardized Web format and application used for the distribution of content from Web pages. In the recent history of the Web, RSS technology was used primarily for content feeds from blogs and other online content sites like newspapers. Now RSS technology plays a critical role in several Web 2.0 technologies such as podcasts and social networks and the Web 2.0 applications that use RSS technology continue to increase. Therefore, it is important to have a basic operational knowledge of RSS in order to effectively use many Web 2.0 applications.

Feeds are the actual content items that are posted on a website. RSS syndicates all of the content and will send everything that has been requested. Any site with one of the following icons will generate RSS feeds: - Feed Icon; XML - XML Icon; and RSS - RSS Icon.

Another type of feed is the Atom feed. Atom was developed as an alternative to RSS because of some dissatisfaction with RSS. Atom is widely-adopted but incompatible with RSS. The Atom feed can be downloaded by websites that syndicate content from aggregators that subscribe to Atom feeds. The intention of Atom was to ease the difficulty of developing applications with web feeds.

When feeds are received, there must be some way of viewing the content associated with the feed. An application that collects RSS feeds for later viewing is called an aggregator, feed reader, or news reader. An aggregator is a program or website that collects RSS feeds for viewing or reading. Aggregators can be either Web-based, an extension of a browser or email program, or a stand-alone program that is installed on the user's computer or desktop.

Desktop aggregators are designed to maintain RSS subscriptions and then collect Web feeds and group them together using a user-friendly interface, usually resembling the interface of popular e-mail clients. Web-based aggregators are hosted on remote web servers and use a web service to maintain subscriptions and receive the Web feeds into an account the user sets up on the Web-based aggregator website. The advantage of a Web-based aggregator over a client aggregator is that it is available through the Web and so it can be accessed anywhere by a user with an Internet connection. Some Web-based aggregators that can be used in schools and classrooms are Bloglines (http://www.bloglines.com), Netvibes (http://www.netvibes.com/) and Google Reader (http://www.google.com/reader). Microsoft Outlook, Firefox, Internet Explorer, and Safari all have reader extensions that can be embedded into the applications.

An example of how RSS feeds and aggregators can be used in the classroom can be demonstrated by an English teacher who is teaching a writing unit on current events. The teacher makes the assignment for students to read articles on current event topics from several major newspapers and blogs and then write a theme about the issue. The teacher can subscribe to the RSS feeds from several relevant and appropriate blogs and newspapers. Students can then open the aggregator and read the stories without having to find and retrieve the content from its original source (either paper or digital). Additionally, the teacher can delete any content from the aggregator that is not relevant to the assignment or appropriate to the age-level of the student.

RSS is becoming a valuable tool for collecting and viewing digitally archived knowledge. RSS feeds can provide teachers and students with the opportunity to evaluate and filter content on the Web. For example, RSS can help teachers manage and review student postings on a school blog. When combined with other Web 2.0 technologies, applications, and services, RSS feeds can help focus and refine the process of conducting research and generating content based on new information.

Social Bookmarking and Folksonomies

According to Wikipedia, social bookmarking is a method for Internet users to store, organize, search, and manage bookmarks of Web pages on the Internet with the help of metadata ("Social Bookmarking," 2008). Social bookmarking is particularly useful for collecting Internet resources (links to resources) that are to be shared with others. Social bookmarking allows users to save bookmarks (links to Web pages known as URLs or Website addresses) that may be accessed in the future to a public website where it is annotated with descriptive information, tagged with keywords or descriptors, and designated as public or private. Registered users of the website can browse or search the website and view the public bookmarks, tags, and classification schemes that other registered users have created.

The tags used by social bookmarking services are folksonomic. Folksonomic tagging is the practice of collaboratively creating and managing classifications or categorizations of content or data by the creators and consumers of the content as opposed to the traditional indexing schemes that are created by subject-matter experts. Thus, a folksonomy is a user generated taxonomy—a taxonomy created by the "folks" who use it.

Folksonomic tagging is intended to make information easy to search and navigate because it uses a shared vocabulary that is originated by its primary users. Folksonomies arise where user-generated content such as pictures or videos is shared or where existing content such as websites, books, scholarly works, and blog entries are collaboratively tagged.

A shift from the use of formal taxonomies or indexes to folksonomic taxonomies has important implications for teaching and learning because it changes the way information is stored and retrieved. In other words, it may become less important for students to know where information is found and more important to know how to retrieve it using a framework created by their peers.

Social bookmarking was launched by the advent of Joshua Schacter's del.icio.us (Alexander, 2006). Del.icio.us (http://del.icio.us/) is a service for storing, describing, and sharing bookmarked web pages online, which allows access to the bookmarks and additions to the bookmarks from any computer. Users register with del.icio.us and create their own del.icio.us account (my del.icio.us). Users can annotate each URL with a line of text describing the bookmarked URL and tag it with one or more keywords or descriptors to help organize and remember the bookmark. A user can be a group; thus, a group of students or a whole class can have a shared del.icio.us account to archive Internet-based research pertaining to a specific project or multiple projects.

With del.icio.us bookmarks can be shared publicly (or not) so that peers and other people can view them for reference and collaboration. Additionally, a user can browse and search del.icio.us for interesting and useful bookmarks of other users, which is made easy with tags, and then add other's bookmarks to one's own collection. RSS feeds can be found on the bottom of almost every page within del.icio.us and the index can be used to subscribe to other people's feeds.

Educators are finding numerous ways to use social bookmarking in the classroom. For example, the teacher can research existing sites to find appropriate and relevant articles, documents, or multimedia resources. The teacher can then direct students to conduct research for a project using the designated bookmarks. Another approach is for individual students, student teams, or even the whole class to use social bookmarking services for collaboration and sharing common information in regard to a specific project or multiple projects. Students select and archive their own resources on a given topic and then share those links with their peers. A group account can be established or students can join groups with similar interests.

Some social bookmarking sites allow teachers to review and comment on resources the students have bookmarked. Other sites allow users to post notes directly to the account's Web page and then teachers can verify if a student has linked to online resource and if they have understood what they have read or viewed based on the notes they have posted. Schools or classes can then place links in their home page to a social bookmarking service. A school may want to share social bookmarking accounts among the teachers in a certain department or even between different departments for interdisciplinary projects. Some social bookmarking sites provide citation services that will create a bibliography on a new Web page so bibliographic information can be cut and pasted into a document.

Some other social bookmarking sites that can be used in schools and classrooms include Edtags (http://www.edtags.org), Diigo (http://www.diigo.com/), and Furl (http://www.furl.net/).

Social Writing: Blogs and Wikis

A blog (short for Web log) is a tool that allows authors to quickly and easily publish (or post) content similar to that of a diary or journal on the Web. According to Wikipedia, blogs are usually maintained by an individual with regular entries of text commentary or other material such as graphics or video that are displayed in reverse chronological order ("Blog," 2008). While many blogs provide commentary or news on a particular subject, others function as more personal online diaries.

Blog sites are organized like conventional websites. A blog page may include text, graphics, and navigation links much like a standard Web page. Blog sites, however, are more dynamic than standard websites because new content is posted to a blog on a daily (or more often) basis. Each new blog entry or posting starts a thread for subsequent comments (responses) made by persons reading the blog entry. Postings are often short and frequently updated and may contain text, images, and links to other blogs, Web pages, or media related to its topic. Postings appear in reverse chronological order and can include archived entries.

Edublogs (http://www.edublogs.org/) is an example of a blog service that provides online hosting for educational blogging. Edublogs is a free service without any advertising, ample uploading space, and numerous features and currently hosts hundreds of thousands of blogs for teachers, and students and other educators. With Edublogs students and teachers can upload or copy and paste information into the blog page. The user can manage who gets access to the blogs through password and plugin safety measures. Edublogs can be used to connect multiple student and teacher blogs and the teacher can manage and edit blog posts and responses through an administrative panel. Edublogs permits the embedding of online video, multimedia presentations, and slideshows into blogs. Multiple blogs are easily created so it is easy to set up a dedicated blog for a specific project or event. Edublogs can even be used to create a multi-layered, multimedia-rich website that does not appear to resemble a blog.

Wikis take social writing and interaction a step further by allowing collaborative editing of a document on the Web. According to Wikipedia ("Wiki," 2008) a wiki is a collection of Web pages designed to enable anyone who accesses it to contribute or modify content. Wiki platforms can be used to create collaborative websites and power community websites. One of the best known wikis is Wikipedia, a collaborative, online encyclopedia. A wiki can be edited by its readers while a blog is written by one person and everyone else reads it and makes comments.

Wikis permit groups to work collaboratively on the content of the site using nothing but a standard Web browser. The wiki platform tracks the history of a document as it is revised. When a revision to the content takes place, the revised version becomes the current version and an older version is archived.

Blogs and wikis work well in classrooms because they are amazingly simple to implement and easy to use, requiring minimal technical knowledge. Blogs can be effortlessly created, edited, and updated at any time from any place from a computer with Internet access. Thus, teachers can extend the boundaries of classroom learning to where students live and play. Blogs can be a powerful tool for enabling learning because they provide authentic and convenient opportunities for students to read, write, and discuss collaboratively.

Teachers can use blogs or wikis as a portal to create and cultivate the K-12 classroom as a community of learners. Blogs can be used not only to scaffold learning but to perform the management and coordination tasks of a learning community including the posting of handouts and assignments. Blogs can provide a space where teachers and students work together to accomplish learning goals. Peer review is a basic or embedded feature of a blog and teachers can provide online mentoring for student blogs. Blogs can facilitate substantive discussions about a topic or issue both within and outside of the classroom because they provide the opportunity and time for students to reflect on learning. Wikis can be used to allow students to collaborate on a group report, compile data, or share the results of their research. Teachers in a particular grade-level or department might use a wiki to develop curriculum, class assignments, or lesson plans.

Some other blog and wiki sites that can be used in schools and classrooms include Class Blogmeister (http://classblogmeister.com/), Bloglines (http://www.bloglines.com/), and Wikispaces for Educators (http://www.wikispaces.com/site/for/teachers).

Social Networking and Media Sharing

Boyd and Ellison (2007) define a social network site as a Web-based information-sharing service that allows individuals to construct a profile within a restricted system, delineate users with whom they share a connection, and view and navigate a list of connections and those made by others within the system. The primary feature of social network sites, according to Boyd and Ellison, is not so much that users are permitted to meet strangers, but that users are enabled to publicly declare their social networks. Myspace (http://www.myspace.com) is the most popular example of a social network.

Safe social networks, or smart social networks as defined by Yarmosh (2006) place certain limitations on the connectivity among users. A safe or smart social network permits users to manage who contacts them, define who can comment on posts and pictures, and remove their profile from the search index. Yarmosh says that smart social networks bring intelligence into the network by permitting users to define and manage their online relationships, which makes smart social networks more appealing. Facebook (http://www.facebook.com) is widely used in higher education circles and permits users to control how they share their information and who can see it. The safe or smart social network is the better application for K-12 classroom integration of social networking.

The use of social networking in education focuses on allowing students to construct a learning landscape. Users can create new social networks in very little time, with no technical skill required. Once a name and a URL are selected, the user indicates whether the network is private (only invited people can view or join) or public; writes a tag-line and description of the network; assigns keywords; chooses from a selection of features (such as photos or videos, a blog, events, groups, or gadgets) and uses drag-and-drop tools to place those features on the page; chooses a visual theme (colors, fonts, sizes) and can customize these choices; and decides what information users will be asked to provide to join the network. If membership is restricted, the creator can invite individuals to join. RSS feeds let users subscribe to updates from specific parts of the social network.

Today's students spend countless hours on Facebook and MySpace. Using social networking in the classroom provides an opportunity for teachers to take advantage of an experience that is familiar and comfortable to students in order to engage them in learning experiences. Social networks are a model for how a community of learners functions because they establish a social and collaborative environment that meets the needs of its members and they establish standards for interaction among its members. By creating social networks around academic topics or projects, a teacher can facilitate a strong sense of community that facilitates personal interactions with the goal of creating collective knowledge. Social networks in the K-12 classroom can provide an opportunity for students to cultivate and sustain a network of peers similar to a network of professional contacts and relationships and to view those relationships in the broad context of learning.

Elgg (http://www.elgg.org/) defines itself as a personal learning landscape—a social network platform with multiple capabilities including eportfolios, tagging, blogging, podcasting, and an RSS reader. Elgg combines capabilities for personal Web publishing with the capabilities of social networking. Elgg differs from a regular blog or a social network by giving users control over who can access their content. Each profile item, blog post, or uploaded file can be assigned its own access restrictions from fully public to only readable by a particular group or individual. Elgg users can register a free account on Elgg.net, have their own installation of the application hosted on Elgg.net, or download Elgg and host it on their own Web server. However, a certain amount of technical knowledge is required to maintain an Elgg server.

Elgg is designed to provide deep learning through conversational immersion over time. According to Campbell, Ammann, and Dieu (2005) learners are encouraged to write a weekly blog on topics that are relevant to their own interests. They can then tag their posts with keywords and search for other Elgg users who are writing about similar topics. Elgg users can be added to the contact lists, can join communities that are relevant to their interest, and can use the file repository to share audio messages, photos, or short videos. Teachers can take part in the activities as peer facilitators to help students make connections and to provide comments and feedback. Teachers can also monitor and participate in student activities.

As the phenomenon of social media has expanded, websites that were focused only on media sharing began deploying social networking features and becoming social network sites themselves (Boyd and Ellison, 2007). Some examples of media sharing sites with social networking features include Flickr (photo sharing), Last.FM (music listening), and YouTube (video sharing).

The photo-sharing site Flickr (http://www.flickr.com/) can be used in K-12 classrooms as a resource for images used in presentations, projects, and portfolios. Because many of the images uploaded to Flickr carry a Creative Commons license, they are suitable for educational use. The folksonomic tagging of images makes it much easier for students to find relevant content. Students can also use Flickr to publish their digital photography to a wider audience. Flickr includes the capability to add hot-spots to an image so that portions of images can be annotated.

VoiceThread (http://www.voicethread.com/) allows users to create an online media album that can hold multiple forms of media including images, text, and videos. Commentaries can be added to the media using a mixture of voice using a microphone or telephone, text, audio file, or video using a Webcam and shared or exported to an archival movie for offline use as a DVD or MP3 file. A VoiceThread allows group conversations to be collected and shared in one place, from anywhere in the world. VoiceThread has made its premium account available to K-12 educators for free.

Some other social networking and media sharing sites that can be used in schools and classrooms include Classroom 2.0 (http://www.classroom20.com/), Ning (http://www.ning.com/), and Imbee (http://www.imbee.com/).

Multimedia Broadcasting: Podcasting, Webcasting, Webconferencing, and Video Blogging

A podcast is an audio mini-program, in MP3 format, broadcast over the Internet. Podcasts can be downloaded and listened to on any MP3-compatible digital music player such as Apple's iPod. Users can either download a podcast once or subscribe to the RSS service for regular or periodic downloads. Podcasts can also be downloaded to a computer using podcasting applications such as iPodder. The producer creating the podcast, called a podcaster, can easily create podcasts with a microphone, a computer, videoediting software, a tool to generate RSS files, and ample server space to host large files. Podcasting is useful for the K-12 classroom because it easy and generally free for listeners (students) and minimal costs for producers (teachers).

Podcasting allows instruction to become portable. Podcasting is useful in the K-12 classroom because students are already familiar with the underlying technology. Instructional podcasting can promote the use of iPods and MP3 players not only for entertainment but also for educational experiences. For example, with podcasting teachers can create or record lesson content for students who miss class or provide access to subject-matter experts through interviews. Additionally, students can create their own podcasts as a record or log of classroom or project activities, a way to collect notes for a project or on a lesson, or a reflection on what they have learned.

A webcast is a video/audio file that is distributed over the Internet using streaming media technology. A webcast can be either be live or recorded, and can be distributed live (synchronous) or recorded (asynchronous). Essentially, webcasting is the transmission of linear audio or video content over the Internet to many simultaneous listeners or viewers.

With the emergence of Web 2.0 technologies webcasting provides a relatively simple and inexpensive option for synchronous and asynchronous mass communication anywhere in the world. For most online events that use webcasting, all that is needed is a computer with an Internet connection and speakers. While connecting to a webcast is a relatively simple process, transmitting live or recorded webcasts requires the capability to capture and produce video content—usually using a video camera, firewire, and videoediting software. The final cut of the video production must then be encoded to convert it to a streaming format using encoding software such as Windows Media Encoder for a Windows-based computer broadcasting a Windows Media stream or QuickTime Broadcaster for a Macintosh computer broadcasting a QuickTime stream.

Webconferencing is similar to webcasting but with functionality such as electronic whiteboards and chat. Webconferencing offers a way to engage students in fully interactive, online learning experiences; however webconferences can also be used for tutoring and online office hours.

Webconferencing applications use common browser plug-ins and connect through a local or remote hosting service. At the scheduled time, participants log on to a website to join class sessions, participate in online office hours, or take part in other scheduled events. The webconference window usually includes a pane that lists current participants, a chat pane for written interaction, an audio/video pane, and a content window. The audio/video pane can show only the instructor or presenter or it can include other users if they have webcams. Many applications use voice over Internet protocol (VoIP) for the audio segment, eliminating the need for a separate phone connection. The content pane shows applications from the presenter's desktop, which can include text or multimedia resources.

Presenters can be seen and heard in real time by session participants, who can communicate with one another and the instructor through the chat pane, the audio and video, or tools such as a shared whiteboard. The instructor can respond to questions from participants, demonstrate applications, and share access to them in the content pane, as well as manage the layout of the environment. Sessions can be recorded and archived for later access and can be converted for playback on portable devices.

Webconferences can be used in K-12 classrooms in a number of ways. Webconference technology allows distant groups of students to interact over the Web, work on shared topics, and build a learning community. Webconferences offer an easy way to bring subject-matter experts into a classroom. Webconferences provide an alternative to asynchronous online instruction because many students are more engaged when they can see and hear instructors, seek clarification, and communicate in real time.

A videoblog, or vlog, is a blog using video rather than text or audio as its primary media source. Cell phone cameras and digital cameras that record short video sequences or inexpensive video cameras usually provide the raw footage of a videoblog. Videoblogs are usually accompanied by text or still images, and some vlogs include folksonomic tagging. Digital videoediting software is often used to produce high quality video segments that include background music and special effects.

A videoblog is updated regularly like a text blog. Like a text blog, a videoblog offers a simple mechanism for subscription and delivery through RSS feeds. Videoblogging can offer a richer and more intense Web experience than text blogging because it combines movies, audio, images, still photos, and text. Because it is becoming easier to record and edit video segments and quickly post them to a website, videoblogs can be a useful tool for recording classroom demonstrations, lectures, and lab experiments. Videoblogs can also be used for personal expression and reflection and are useful for eportfolios, presentations, and digital storytelling.

Some multimedia broadcasting applications or services that can be used in schools and classrooms include Podomatic (http://www.podomatic.com/), Audacity (http://audacity.sourceforge.net/), the podcasting section of iTunes has a category dedicated to education, Microsoft Office Live Meeting (http://office.microsoft.com/en-us/livemeeting/), Wimba Classroom (http://www.wimba.com/products/wimbaclassroom/), and Youtube (http://www.youtube.com/);

CONCLUSION

Web 2.0 has significantly lowered the barriers to access and effective use of technology to supplement and enhance instruction and to impact teaching and learning in the K-12 classroom. It is relatively simple to embed a del.icio.us tag, a classroom blog, or a Web conference with a subject-matter expert into a PBL activity. While the future of Web 2.0 is emergent, the path from the previous generation of Internet technologies to Web 2.0 demonstrates that subsequent generations of Internet technologies may become a normal, if not requisite, part of mainstream pedagogy.

Many of the features of Web 2.0 have great potential for instructional use that makes it more than just another medium for the delivery of instruction. When Web 2.0 applications and services are embedded into a PBL approach to learning, teachers can implement powerful learning experiences that facilitate independent and collaborative student-centered learning experiences. Web 2.0 allows teachers to engage students in learning experiences with authentic and relevant learning contexts. Web 2.0 provides scaffolds that accommodate collaborative PBL.

With Web 2.0, teachers have tools to create high-impact learning experiences where students work in-depth with content to express their knowledge and understanding of the content. Thus, Web 2.0 can play a critical role in the K-12 classroom by establishing PBL environments and experiences that educate students for the 21st century.

KEY TERMS AND DEFINITIONS

Blog: Short for Web log, a blog is a Web 2.0 technology that allows authors to quickly and easily publish (or post) content similar to that of a diary or journal on the Web. Blogs consist of regular or periodic entries of text commentary or other material such as graphics or video that are displayed in reverse chronological order. Some blogs provide commentary or news on a particular subject while others function as more personal online diaries. Blog entries are often short and frequently updated. Blogs are organized much like conventional Web pages and may include text, graphics, and navigation links. Each new blog entry starts a thread for subsequent comments made by persons reading the blog entry.

Collaborative Learning: A variety of instructional approaches that involve shared intellectual efforts by peers and/or experts. Collaborative learning generates dialog and interaction among peers or communities of peers and experts for the purpose of constructing collective knowledge or shared understanding about a concept, case, or problem. Peers work in groups of two or more to search for a mutual understanding, solution, or meaning and to create a product based on their shared learning experience.

Folksonomic Tagging: The practice of collaboratively creating and managing classifications or categorizations of content or data by the creators and consumers of the content instead of using traditional indexing schemes that are created by subject-matter experts. Thus, a folksonomy is a user generated taxonomy. Folksonomies arise when existing content such as websites, books, scholarly works, blog entries, pictures or videos are collaboratively tagged. Folksonomic tagging is intended to make information easy to search and navigate because it uses a shared vocabulary that is originated by its primary users.

Podcast: An audio mini-program in MP3 format that is broadcast over the Internet. Podcasts can be downloaded and listened to on any MP3-compatible digital music player such as Apple's iPod. Users can either download a podcast once or subscribe to an RSS service for regular or periodic downloads. Podcasts can also be downloaded to a computer using podcasting applications.

Problem-Based Learning: Also known as project-based learning, PBL is an instructional methodology that helps students construct an individual understanding of a problem and then develop and present a solution. With PBL the teacher guides students through a problem-solving process. Students first reason through the problem and apply knowledge they already have to the problem and then students research and acquire information about the problem and reach possible solutions. PBL generally situates learning in real-world problems and allows students to develop solutions through collaborative processes.

RSS Feeds: Also known as news feeds or Web feeds, RSS feeds are the actual content items that are published on Web pages and generated by RSS. RSS stands for Rich Site Summary or Really Simple Syndication and is a Web 2.0 technology used for the syndication of content from Web pages. RSS allows users to subscribe and receive the RSS feeds and view the content without visiting the original website. With RSS, content from Web pages comes to the user rather than user going to get the content.

Social Bookmarking: A Web 2.0 service for storing, describing, and sharing bookmarked Web pages online, which allows access to the bookmarks and additions to the bookmarks from any computer connected to the Internet. Users register with the social bookmarking service and create their own account comprised of annotated and tagged navigation links (URLs). The social bookmarking service usually permits the bookmarks to be annotated with a line of text describing the link and then tagged with one or more keywords or descriptors to help organize and remember the bookmark. A widely used social bookmarking site is Del.icio.us (http://del.icio.us/)

Social Networking: A Web-based information-sharing service that allows individuals to construct a profile within a restricted system, delineate the users with whom they want to share a connection, and view and navigate a list of connections and those made by others within the system. The primary feature of social network sites is that users are enabled to publicly declare their social networks. Myspace (http://www.myspace.com) is the most popular example of a social network.

Web 2.0: A term used to identify Web technologies that harness collective intelligence, provide interfaces and services across multiple devices, and enhance collaboration. Examples of Web 2.0 applications, services, and technologies are blogs, podcasts, social bookmarking, social networking, Web feeds, and wikis. Although the designation, Web 2.0, suggests a new version or generation of the World Wide Web, in reality it refers to a re-visioning of the Web.

Wiki: A website that permits collaborative editing of a document on the Web. A wiki is a collection of Web pages designed to enable anyone who accesses it to contribute or modify content. When a revision to the content takes place, the revised version becomes the current version and an older version is archived. A wiki is different from a blog because the content of the Web page can be edited by its readers while blog content is written and posted by one person and then everyone else reads it and makes comments. One of the best known wikis is Wikipedia, a collaborative, online encyclopedia.

Chapter 5.17
Machine Learning and Web Mining: Methods and Applications in Societal Benefit Areas

Georgios Lappas
Technological Educational Institution of Western Macedonia, Kastoria Campus, Greece

ABSTRACT

This chapter reviews research on machine learning and Web mining methods that are related to areas of social benefit. It shows that machine learning and Web mining methods may provide intelligent Web services of social interest. The chapter reveals a growing interest for using advanced computational methods, such as machine learning and Web mining, for better services to the public, as most research identified in the literature has been conducted during the last years. The chapter objective is to help researchers and academics from different disciplines to understand how Web mining and machine learning methods are applied to Web data. Furthermore it aims to provide the latest developments on research that is related to societal benefit areas.

DOI: 10.4018/978-1-59904-657-0.ch005

INTRODUCTION

The Web is constantly becoming a central part of social, cultural, political, educational, academic, and commercial life and contains a wide range of information and applications in areas that are of societal interest. Web mining is the field of data mining that is related to the discovery of knowledge from the Web. The Web can be considered as a tremendously large and rich in content knowledge base of heterogeneous entries without any well specified structure, which proportionally makes the Web at least as complex as any known complex database and perhaps the largest knowledge repository. The vast information that surrounds the Web does not come only from the content of Websites, but is also related to usage of Web pages, navigation paths and networking between the links of Web-pages. All these properties establish the Web as a very challenging area for the machine learning community to apply their methods usually for extracting new knowledge, discovering interesting patterns and enhancing the efficiency of Websites by providing user-demand content and design.

Web mining is a relatively new area, broadly interdisciplinary, attracting researchers from: computer science fields like artificial intelligence, machine learning, databases, and information retrieval specialists; from business studies fields like marketing, administrative and e-commerce specialists; and from social and communication studies fields such as social network analyzers, pedagogical scientists, and political science specialists. Herrera-Viedma and Pasi (2006) denote that due to the complexity of Web research there is a requirement for the use of interdisciplinary approaches like statistics, databases, information retrieval, decision theory, artificial intelligence, cognitive social theory and behavioral science. As a relatively new area there is a lot of confusion when comparing research efforts from different point of views (Kosala & Blockeel, 2000) and therefore there is a need for surveys that record and aggregate efforts done by independent researchers, provide definitions and explain structures and taxonomies of the field from various points of view.

The overall objective of this chapter is to provide a review of different machine learning approaches to Web mining and draw conclusions on their applicability in societal benefit areas. The novelty of this review is that it focuses on Web mining in societal benefit areas. There exist similar work related to Web mining in (Baldi, Frasconi, & Smyth, 2003; Chakrabarti, 2003; Chen & Chau, 2004; Pal, Talwar & Mitra, 2002). Baldi et al. (2003) cover research and theory on aspects of Internet and Web modeling at the information level based on mathematical, probabilistic, and graphical treatment. Chakrabarti focuses on studies that connect users to the information they seek from the Web providing lots of programs with pseudocode. Chen and Chau provide an extended review of how machine-learning techniques for traditional information retrieval systems have been improved and adapted for Web mining applications. Pal et al. (2002) present an overview of machine learning techniques with focusing on a specific Web mining category, the Web content mining that will be described in next section. This work is differentiated from the aforementioned related work as the chapter particularly focuses on Web mining and machine learning that may help and benefit societal areas in ways of extracting new knowledge, providing support for decision making and empowering valuable management of societal issues. This survey aims to help researchers and academics from different disciplines to understand Web mining and machine learning methods. Thus, it is aimed at a relatively broad audience and tries to provide them with a different and more open view on Web research. Therefore this work addresses researchers from both computer science and other than computer science disciplines with the intention: (a) for computer science researchers, to provide them with the latest developments on the theory and applications of Web mining, focusing also to the need for Web mining applications in societal beneficial areas, and (b) for researchers from other than computer science disciplines, to draw their attention to existing machine learning methods that may help them to seek for more effective results in their Web research.

Later in the chapter, some background to the different perspectives of Web mining has been provided with a short review on machine learning methods. Afterwards, a study on related machine learning methods applied to Web mining have been put forward, which is followed by applications related to societal benefit areas. Finally it discusses current trends and future challenges on machine learning and Web mining.

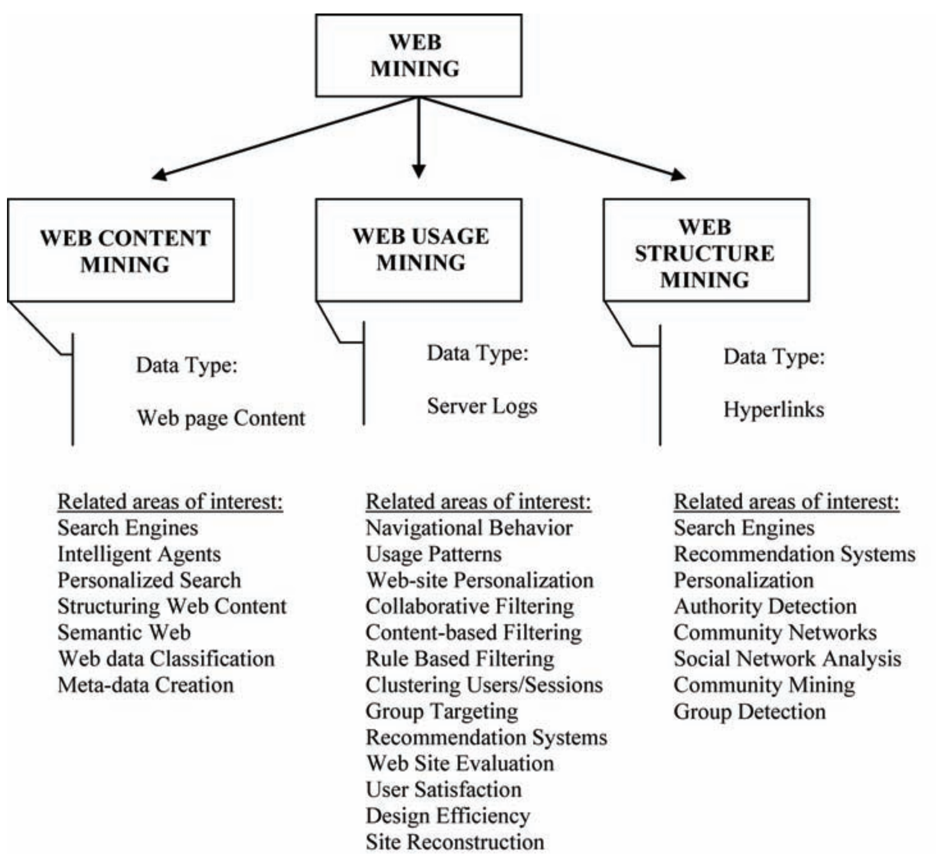
WEB MINING OVERVIEW

The word *mining* means extracting something useful or valuable, such as mining gold from the earth. The expectation of useful or valuable information discovery from the Web is enclosed in the term "Web mining." Definitional, Web mining refers to the application of data mining techniques to the World Wide Web (Cooley, Mobasher & Srivastava, 1997), or else is the area of data mining that refers to the use of algorithms for extracting patterns from resources distributed in the Web. Over the years, Web mining has been extended to denote the use of data mining and other similar techniques to discover resources, patterns and knowledge from the Web and Web-related data (Chen & Chau, 2004).

According to the different sources of data analysis, Web mining is divided into three mining categories. Figure 1 shows the Web mining taxonomy and the sources of data that are used in mining. Moreover, it displays Web mining categories and the related areas of research interest:

a. *Web content mining* focus on the discovery of knowledge from the content of Web pages and therefore the target data consist of multivariate type of data contained in a Web page as text, images, multimedia, and so forth.
b. *Web usage mining* focus on the discovery of knowledge from user navigation data when visiting a Website. The target data are requests from users recorded in special

Figure 1. Taxonomy of Web mining according to source of target data



files stored in the Website's servers called log files.

c. *Web structure mining* deals with the connectivity of Websites and the extraction of knowledge from hyperlinks of the Web.

The above taxonomy is now broadly used in Web mining (Scime, 2005) and has the origins from Coley et al. (1997) who introduced Web content mining and Web usage mining and Kosala and Blockeel (2000), who added Web structure mining.

A well-known problem related to Web content mining, is experienced by any Web user trying to find relevant Web pages that interests the user from the huge amount of available pages. Current search tools suffer from low precision due to irrelevant results (Chakrabarti, 2000). Lawrence and Giles (1999) raise issues related to search engine problems. Search engines are not able to index all pages resulting in imprecise and incomplete searches due to information overload. The overload problem is very difficult to cope as information on the Web is immensely and grows dynamically raising scalability issues.

Moreover, myriad of text and multimedia data are available on the Web prompting the need for intelligence techniques for developing automatic mining using artificial intelligence tools. Such automatic mining is performed by intelligent systems called "intelligent agents" or "agents" that search the Web for relevant information using domain characteristics and user profiles to organize and interpret the discovery information. Agents may be used for intelligent search, for classification of Web pages, and for personalized search by learning user preferences and discovering Web sources meeting these preferences.

Web content mining is more than selecting relevant documents on the Web. Web content mining is related to information extraction and knowledge discovery from analyzing a collection of Web documents. Related to Web content mining is the effort for organizing the semistructured Web data into structured collection of resources leading to more efficient querying mechanisms and more efficient information collection or extraction. This effort is the main characteristic of the "Semantic Web" (Berners-Lee, Hendler & Lassila, 2001), which is the next Web generation. Semantic Web is based on "ontologies," which are metadata related to the Web page content that make the site meaningful to search engines. Sebastiani's study (2002) may be used as a source for Web content mining.

Web usage mining tries to find patterns of navigational behavior from users visiting a Website. These patterns of navigational behavior can be valuable when searching answers to questions like: How efficient is our Website in delivering information? How the users perceive the structure of the Website? Can we predict users next visit? Can we make our site meeting user needs? Can we increase user satisfaction? Can we targeting specific groups of users and make Web content personalized to them?

Answer to these questions may come from the analysis of the data from log files stored in Web servers. A log file is usually a large file that contains all requests of all users to the Website as they arrive in time. Log files may have various formats according to the information stored. The most common format uses information about user IP, date and time of request, type of request (for example get a Web page), a code denoting whether the request has be successfully served or failed, and number of bytes transferred to user. However, Web usage mining should not be confused with tools that analyze log files in order to provide statistics about the site such us: page hits, times of visits, hits per hour or per day or per month, and so forth. While this information might be interesting or valuable for Website owners, they have low data analysis. Web usage mining is more sophisticated as it refers to find users access behavior (Levene & Loizou, 1999) and usage patterns (Buchner, Mulvenna, Anand & Hughes, 1999). It has become a necessity task to provide Web administrators with meaningful information about users and usage patterns for improving quality of Web information and service performance (Eirinaki & Vazirgiannis, 2003; Spiliopoulou & Pohle, 2001; Wang, Abraham & Smith, 2005). Successful Websites may be those that are customized to meet user preferences both in the presentation of information and in relevance of the content that best fits the user.

In this context, Website personalization is the process of customizing the content and structure of a Website to the specific needs of each user taking advantage of user's navigational behavior (Eirinaki & Vazirgiannis, 2003). Recommendation systems support Website personalization by tracking user's behavior and recommending similar items to those liked in the past (content-based learning), or by inviting users to rate objects and state their preferences and interests so that recommendations can be offered to them based on other users rates with similar preferences (collaborative filtering), or by asking questions to the user and providing services tailored to user needs according to the user's answers (rule-based filtering).

On the other hand, content-based filtering is the most common method for Web personalization from server log files and has attracted considerable attention from researchers (Mobasher, Jain, Han, & Srivastava, 1996; Mobasher, Cooley, & Srivastava, 1999; Ngu & Wu, 1997; Spiliopoulou, Pohle, & Faulstich, 1999; Srivastava, Cooley, Deshpande, & Tan, 2000; Wolfang & Lars, 2000) for constructing user models that represent the behavior of users. Such systems usually apply classification methods or clustering algorithms on Web usage data.

Along this perspective, a common methodology for discovering usage and user behavior patterns consists of the following steps: reconstructing user sessions, that is, the navigational sequence of Web-pages of a user in the site; comparing them with other user's sessions; and clustering or classifying the sessions to extract knowledge of navigational behavior. Extracted usage and user behavior patterns may be used in targeting specific groups of users; in various recommendation systems; and in evaluation and reconstruction of the Website to meet design efficiency issues and user satisfaction requirements. Detailed surveys on Web usage mining are presented by Faca and Lanzi (2005), and by Srivastava et al. (2000).

Subsequently, Web structure mining is closely related to analyzing hyperlinks and link structure on the Web for information retrieval and knowledge discovery. Web structure mining can be used by search engines to rank the relevancy between Websites and to classify them according to their similarity and relationship (Kosala & Blockeel, 2000). Google search engine, for instance, is based on PageRank algorithm (Brin & Page, 1998), which states that the relevance of a page increases with the number of hyperlinks to it from other pages, and in particular of other relevant pages. Personalization and recommendation systems based on hyperlinks are also studied in Web structure mining.

Web structure mining is used for identifying "authorities," which are Web pages that are pointed to by a large set of other Web pages (Desikan, Srivastava, Kumar & Tan, 2002) that make them candidates of good sources of information. Web structure mining is also used for discovering "social networks on the Web" by extracting knowledge from similarity links. The term is closely related to "link analysis" research, which has been developed in various fields over the last decade such as computer science and mathematics for graph-theory, and social and communication sciences for social network analysis (Foot, Schneider, Dougherty, Xenos & Larsen, 2003; Park, 2003; Wasserman & Faust, 1994).

This method is based on building a graph out of a set of related data (Badia & Kantardzic, 2005) and to apply social network theory (Wasserman & Faust, 1994) to discover similarities. Thus, a social network is modeled by a graph, where the nodes represent individuals whereas an edge between two nodes represents a direct relationship between the individuals. Recently Getoor and Diehl (2005) introduce the term "link mining" to put special emphasis on the links as the main data for analysis and provide an extended survey on the work that is related to link mining.

A new term, namely, community mining is a major research area on social networks that emphasizes on discovering groups of individuals, who by sharing the same properties form a specific community on the Web. Domain applications related to Web structure mining of social interest are: criminal investigations and security on the Web, digital libraries where authoring, citations and cross-references form the community of academics and their publications etc. Detailed survey on Web structure mining can be found in Desikan et al. (2002) and Getoor & Diehl (2005).

The taxonomy previously described is based on the characteristics of the source data. Usually when working with one of the three data sources (Web content, log files, hyperlinks), researchers might think the corresponding category. However, this is not strict and might combine source data and target application as for example they can use hyperlinks to predict Web content (Mladenic & Grobelnik, 1999). Another example is "Web community" (Zhang,Yu & Hou, 2005), a term closer to Web structure mining, however, is used for the analysis and construction of "Web communities" not only from hyperlinks, but also from Web document content and user access logs. Mobasher, Dai, Luo, Sung, and Zhu (2000) combine Web usage mining and Web content mining for creating user content profiles. Web usage data combined with ontologies and semantics for improving Web personalization are currently proposed in various systems (Berendt, 2002; Dai & Mobasher, 2003; Oberle, Berendt, Hotho & Gonzalez, 2003; Spiliopoulou & Pohle, 2001).

MACHINE LEARNING OVERVIEW

Machine learning is the basic method for most data mining approaches and therefore will be also an important method in Web mining research. It is a broad field of artificial intelligence investigating the use of algorithms acting as intelligent learning methods in computer systems to gain experience, so that this experience can be used when making decisions based on previous learned tasks. The machine learning methods cover a wide range of learning methods, where some of them have been inspired from nature. Neural networks are inspired from human brain and its neurons for the learning, information storing and information retrieval capability. Genetic algorithms and evolutionary algorithms are inspired from Darwin's theory for the surviving characteristics of the fittest in a population that evolves in time. Other machine learning methods are designed to reach to a decision by asking simple yes/no questions following a path from a tree based graph (decision trees) or to derive rules that find interesting associations and/or correlation relationships among large set of data items (association rules).

Representatives of machine learning methods are: artificial neural networks (ANN), self-organizing maps, Hopfield network, genetic algorithms, evolutionary algorithms, fuzzy systems, rough sets, rule-based systems, support vector machines, decision trees, Bayesian and probabilistic models. Describing in details each of these methods will overpass the chapter. The reader can find many textbooks that describe in details all the previously mentioned methods (Bishop, 2003; Duda, Hart & Stork, 2001; Michaklski & Tecuci, 1994; Mitchell, 1997).

At the same time machine learning systems are capable of solving a number of problems related to pattern classification, data clustering, predicting purposes, and information retrieval. In traditional data mining, one can identify that machine learning is used for tackling four types of data mining problems: classification, clustering, association rules and prediction problems.

The task in classification problems is to assign classes to objects according to their characteristics (features). The central aim in designing a classifier is to train the classifier with patterns of known labels drawn out of the total number of available data, which usually are labeled as "positive examples" for samples that belong to a known class and "negative examples" for all those samples that do not belong to the known class. The classifier success is evaluated by the ability to generalize, that is, the ability to predict correctly the label of novel (unseen to the classifier) patterns that have been left out from the training process.

The training process uses an adjustment mechanism that iteratively adjusts the parameters of the classifier in order to get closer to learning the class of the training data. Evaluating classifier generalization one may have an estimation of the performance of the classifier in classifying and predicting labels of newly collected data. Since the class of each data example during the training phase is provided to the classifier, the type of learning is called "supervised learning," where the supervision takes place in adjustments of the classifier parameters so that a misclassified data example in an iteratively learning process is classified correctly.

Classification problems also deal with prediction, as the task in classification is to minimize the error of misclassified test data and therefore classifiers according to the quality of collected data and to the accuracy rate of performance of the classifier may predict classes. In this aspect, prediction is harder when instead of a discrete class one try to find the next value in the range of hypothesis after training the model with historical data, as for example, predicting the closing price of a security in stock-market based on historical financial data.

On the contrary, clustering is a method that uses a machine learning approach called "unsupervised learning," where no predefined classes exist and the task is to find groups of similar objects creating a cluster for each group. Therefore, in a cluster belong data that have similar features between them and at they same time they have dissimilar features with the rest of data. Association rules aims to find relationships and interesting patterns from large data sets.

Although the overwhelming majority of machine learning research is based on supervised and unsupervised learning models, there exist two more types of learning: reinforcement learning and multi-instance learning. Reinforcement learning tries to learn behavior through trial-and-error interactions with a dynamic environment. The difference from supervised learning is that correct classes are never presented, nor suboptimal actions explicitly corrected. In multi-instance learning (Dietterich, Lathrop & Lozano-Perez, 1997) the training data consists of "bags" each containing many instances, while in supervised learning the data set for training consists of positive and negative examples. A bag is labeled positively if it contains at least one positive instance. The task is to learn some concept from the training set of bags for predicting the label of unseen bags. Training bags have known labels, however, the instances have unknown labels so the training process comprises labeled data that are composed of unlabeled instances and the task is to predict the labels of unseen data.

Normally decision trees, and rule-based models are used to solve supervised learning problems; self-organizing maps (SOM), and clustering models are typically used in unsupervised learning problems; and genetic and evolutionary algorithms are typically used in reinforcement learning problems. The rest of machine learning methods are used in both supervised, unsupervised, reinforcement, and multi-instance learning problems.

MACHINE LEARNING APPLIED TO WEB MINING

Machine learning techniques can be very helpful when applied to the process of Web mining. Although there is a close relation between machine learning and Web mining one should denote that Web mining is not actually the application of machine learning techniques on the Web (Kosala & Blockeel, 2000). Other methods studying interesting patterns on the Web may be methods of statistical analysis (Gibson & Ward, 2000; Sharma & Woodward, 2001; Yannas & Lappas, 2005; Yannas & Lappas, 2006), or heuristics (Sutcliffe, 2001).

Primitive Web mining attempts to find patterns to explain various Web "phenomena" can be also found in qualitative Web research methods (Demertzis, Diamantaki, Gazi, & Sartzetakis, 2005; Gillani, 1998; Margolis, Resnick, & Tu, 1997; Maule, 1998; Li, 1998; Reeves, and Dehoney, 1998) that usually rely on observations, annotation of online and archived Web objects, interviews or surveys of Web administrators and users, textual analysis, focus groups, social experiments (Schneider & Foot, 2004) to analyze and explain various Web phenomena.

This approach is usually originated from social science and communication researchers, where the ability to apply more advanced computerized methods like machine learning is limited, however, the interesting of such methods is the expressive power to interpret and explain such phenomena. To the best of our knowledge the author has not identified any combined machine learning and qualitative studies. It could be very interesting to see how such studies will be empowered from the intelligence and automations of machine learning and from the interpretation ability of social sciences.

In comparison to data mining, Web mining may have a few common characteristics similar to machine learning methods and approaches. However, working with Web data is more difficult due to fact that Web data are formed dynamically, change frequently, and their structure cannot be stored in a fixed length database with known features and characteristics. On the contrary, most data mining systems are well structured and remain static over time. Moreover, Web data have many different data type such as text, tables, links, sidebars, layouts, images, audio, video, pdf files, word files, postscript files, executable files, animation files, and so forth, to name a few. Detection of such data types can be a hard problem that needs considerable effort to solve it as with table detection in Websites, where support vector machines and decision trees can be used for attacking this problem (Wang & Hu, 2002). Lastly, the Web is considerably larger than traditional databases in terms of magnitude due to the billions of existing Websites. Before going to the next section, the author presents an indicative research that relates machine learning with the three Web mining categories.

Machine Learning and Web Content Mining

Intelligent indexing text on the Web is the primary goal of search engines building their databases. Machine learning techniques and Web content mining are widely used in this task. Neural networks are commonly used for Web document classification. They are trained by existing Web date for learning to correctly classify patterns of Web documents. They produce high classification accuracy and are very popular among researchers for learning and classifying Web documents (Cirasa, Pilato, Sorbello, & Vassallo, 2000; Fukuda, Passos, Pacheco, Neto, Valerio, & Roberto, 2000; Pilato, Vitabile, Vassallo, Conti, & Sorbello, 2003).

Apart from neural networks classifiers, systems based on support vector machines for Web document classification are presented in Sun, Lim, and Ng (2002), and Yu, Han, and Chang (2002), whereas Esposito, Malerba, Di Pace, and Leo (1999) use three different classification models (decision trees, centroids and k-nearest-neighbor) for automated classification of Web pages; whereas hybrid systems like in Kuo, Liao, and Tu (2005) combine neural networks with genetic algorithms to analyse Web browsing paths for a recommendation system based on intelligent agents.

Also, Bayesian classifiers for text categorization in Syskill and Webert (Pazzani & Billsus, 1997) are used in a recommendation system to recommend Web pages, and in Mooney and Roy (2000) to produce content-based book recommendations. Semeraro, Basile, Degemmis, and Lops (2006) train a Bayes classifier that infers user profiles as binary text classifiers (likes and dislikes) in an application that acts like a conference participant advisor that suggests conference papers to be read and talks to be attended by a conference participant.

Similarly, reinforcement learning and Bayes networks are used as intelligent agents in Rennie and McCallum(1999) for learning and classifying efficiently Web documents. Stamatakis, Karkaletsis, Paliouras, Horlock, Grover, and Curran (2003) compare various machine learning approaches (decision trees, support vector machines, nearest neighbour classifier, naïve baies) for identifying domain-specific Websites.

Machine Learning and Web Usage Mining

Classifiers and clustering algorithms are usually used for analyzing hyperlinks in Web usage mining. Pierrakos, Paliouras, Papatheodorou, Karkaletsis, and Dikaiakos (2003) use clustering applied to Web usage mining for creating community specific directories to offer users a more personalized view of the Web according to their preferences. Hu and Meng (2005) present a system that combines the intelligent agent approach with collaborative filtering using neural networks and Bayes network in order to retrieve relevant information. Zhou, Jiang, and Li (2005) apply multi-instance learning on Web mining by using the browsing history of the user in the Web index recommendation problem for recommending unseen Web pages.

Yao, Hamilton, and Wang (2002) combine three different machine learning techniques: association rules, clustering and decision trees to help users navigate a Website by analysing and learning from Web usage mining and user behavior. A hybrid approach that uses self-organizing maps (SOM), (Kohonen, 1990) and a neuro-fuzzy model is applied on log files by Wang et al. (2005) for Web traffic mining in order to predict Web server traffic. Genetic algorithms are used in (Tug, Sakiroglu & Arslan, 2006) for the discovery of user sequential accesses from log files.

Machine Learning and Web Structure Mining

The most famous application of Web structure mining is the Google search engine based on Brin and Page's (1998) PageRang algorithm for ranking pages relevance. Mladenic and Grobelnik (1999) use the k-nearest-neighbor algorithm to train a system for predicting Web content from hyperlinks. Wu, Gordon, DeMaagd, and Fan (2006) use principal cluster analysis to identify a small number of major topics from millions of navigational data. Lu and Getoor (2003) apply classifiers for link-based object classification. Probabilistic models are used in Matsuo, Ohsawa, and Ishizuka (2001) for Web search and identifying Web communities; in Lempel and Moran, (2001) for Web search; Cohn and Chang, (2000), Getoor, Segal, Tasker, and Koller (2001), and Richardson and Domingos, (2002) for Web page classification.

APPLICATIONS OF WEB MINING TO SOCIETAL BENEFIT AREAS

Web mining may benefit those organizations that want to utilize the Web as a knowledge base for supporting decision-making. Pattern discovery, analysis, and interpretation of mined patterns may lead to take better decisions for the organization and for the provided services. E-commerce and e-business are two fields that may be empowered by Web mining with lots of applications to increase sales, doing intelligence business or even used in crisis management as in Tango-Lowy and Lewis (2005), where Web mining and self organizing maps are used in crisis scenarios.

Lots of Web mining applications found in the literature describe the effectiveness of the application from the Web administration point of view. The target in these applications is taking advantage of the mined knowledge from the users to increase the benefits of the organization. In this chapter, the author focuses on social beneficial areas from Web mining, and hence the point of view is on Web mining applications that can help users or group of users. An obvious societal benefit is that Web mining research efforts lead to user (or group of users) satisfaction by providing accurate and relevant information retrieval; by providing customized information; by learning about user's demands so that services can target specific groups or even individual users; and by providing personalized services. The author identified research on the following areas, where Web mining offers societal benefits: Helpdesks and recommendation systems; digital libraries; security and crime investigation; e-learning; e-government services; and e-politics and e-democracy.

Helpdesks and Recommendation Systems

Recommendation systems are based on user modeling that are mainly derived from content-based learning or from collaborative filtering (Zukerman & Albrecht, 2001). Content–based learning uses a user's past usage behavior and acts as an indicator of his/her future behavior. Collaborative filtering is based on ratings of user favors, like rating music or movies, so that rating history of a user can be associated with similar preferences of other users. So a user is classified in a user model, where recommendations can be addressed to the user according to favors of other people from the specific classified user model. Hybrid recommendation systems that take benefits from both collaborative filtering and content-based learning have been also investigated in literature (Melville, Mooney, & Nagarajan, 2002; Sarwar, Karypis, Konstan, & Riedl, 2000).

Martin-Guerrero, Palomares, Balaguer-Ballester, Soria-Olivas, Gomez-Sanchis, and Soriano-Asensi (2006) propose a recommender model for predicting user preferences based on common clustering algorithms in a citizen Web portal. Clustering and collaboration filtering is used in Hayes, Avesani, and Veeramachaneni (2006) for a blog recommendation system. A blog is a journal-style Website usually written by a single user, where entries are presented in a reverse chronological order.

ReferralWeb (Kautz, Selman & Shah, 1997) is a project that mines social networks from the Web by using collaborative filtering for identifying experts that could answer questions asked by individuals. Nasraoui and Pavuluri (2004) using neural networks provide accurate Web recommendations based on a committee of predictors. Yao et al. (2002) created PagePrompter, an agent-based recommender that helps users navigate a Website by analysing and learning from Web usage mining and user behavior. The interesting part of Pageprompter is that it combines three different machine learning techniques: association rules, clustering, and decision trees for achieving its task.

Pierrakos et al. (2003) use clustering applied to Web usage mining for creating community specific directories to offer users a more personalized view of the Web according to their preferences and may be assisted by using these directories as starting points on their navigation. Garofalakis, Kappos, and Mourloukos (1999) studied Website optimization using Webpage popularity. Scheffer

(2004) created an e-mail answering assistant by semisupervised text classification.

Fast and accurate Web services are practical implications from improved helpdesks and recommendation systems.

Digital Libraries

Digital libraries provide precious information distributed all around the world without necessarily having the need to be physically present in a traditional library building. In this context, Web mining research aiming to offer better services on digital libraries have been identified in literature. Adafre and Rijke (2005) use clustering for discovering missing hypertext links in Wikipedia, the largest encyclopedia on the Web that is created and modified by many volunteer authors. Web mining on Wikipedia is also investigated by Gleim, Mehler, and Dehmer (2006). Bhattacharya and Getoor (2004) use clustering for detecting group of entities, like authors, from links and resolving the coreference problem of multiple references to the same paper in autonomous citation indexing engines, like CiteSeer (Giles, Bollacker, & Lawrence, 1998).

CiteSeer is an important resource for computer scientists for searching electronic versions of papers. Cai, Shao, He, Yan, and Han (2005) work also is based on another well-known digital library in computer science community, the DBLP library at http://dblp.uni-trier.de. Their work is related to machine learning feature extraction algorithms in order to discover hidden communities in heterogeneous social networks. Graph analysis for discovering Web communities can be modeled by using Bayesian networks as demonstrated by Goldenberg and Moore (2005) for identifying coauthorship networks.

A content-based learning book recommendation system is proposed by Mooney and Roy (2000) based on Web pages of the Amazon online digital store. Large portals with news updated frequently per day consist of rich information and may be considered as part of digital libraries in the way that newspaper articles are indexed and available to readers in traditional libraries.

At the same time, news sites are large portal sites that increase their content on a daily basis. For such sites, the interpretation of Web content to meaningful content can be classified into semantic categories in order to make both information retrieval and presentation easier for individuals and group of users is very important (Eirinaki & Vazirgiannis, 2003). Liu, Yu, and Le (2005) use fuzzy clustering to identify meaningful news patterns from Web news stream data. However, the wide distribution of knowledge on the one side and the easiness of access to this knowledge on the other side from various groups of people like researchers, academics, students, pupils, professionals or independents are the most valuable practical implications of Web mining to this societal interest area.

E-Learning

Web mining may be used for enhancing the learning process in e-learning applications. Bellaachia, Vommina, and Berrada (2006), introduce a framework, where they use log files to analyze the navigational behavior and the performance of e-learners so that to personalize the learning content of an adaptive learning environment in order to make the learner reach his learning objective. Zaiane (2001) studies the use of machine learning techniques and Web usage mining to enhance Web-based learning environments for the educator to better evaluate the learning process and for the learners to help them in their learning task. Students' Web logs are investigated and analysed in Cohen and Nachmias (2006) in a Web-supported instruction model. Improved e-learning services that accommodate user needs are practical implications from Web mining and machine learning to the e-learning area.

Security and Crime Investigation

Web mining techniques may be used for identifying cyber-crime actions like Internet fraud and fraudulent Websites, illegal online gambling, hacking, virus spreading, child pornography distribution, and cyberterrorism. Chen, Qin, Reid, Chung, Zhou, and Xi (2004) note that clustering and classification techniques can reveal identities of cybercriminals, whereas neural networks, decision tress, genetic algorithms, and support vector machines can be used to crime patterns and network visualization. Chen et al. (2004) provide a detailed study on methods against terrorist groups on the Web for predictive modeling, terrorist network analysis, visualization of terrorists' activities, linkages and relationships.

Similarly, Wu et al. (2006) based on user's online activities use principal cluster analysis to identify a small number of major topics from millions of navigational data in an approach that can be useful in security against terrorism. Do, Chang, and Hui (2004) implemented a system that can benefit safe Internet browsing in school, home and workplace. The system monitors and filters Web access by applying Web mining for performing Web data classification in order to classify Web data in a "white list" of allowed pages or blacklist of blocked Web pages. Social Networks extracted from instant messaging by using clustering is investigated by Resig, Dawara, Homan, and Teredesai (2004). Enjoying a more secure environment having better online and offline protection are implications of Web mining and machine learning to this societal interest area.

E-Government Services

The processes through which government organizations interact with citizens for satisfying user (or group of users) preferences leads to better social services. The major characteristics of e-government systems are related to the use of technology to deliver services electronically focusing on citizens needs by providing adequate information and enhanced services to citizens to support political conduct of government. Empowered by Web mining methods e-government systems may provide customized services to citizens resulting to user satisfaction, quality of services, support in citizens decision making, and finally leads to social benefits. However, such social benefits mainly rely on the organization's willingness, knowledge, and ability to move on the level of using Web mining.

The e-government dimension of an institution is usually implemented gradually. E-government maturity models (Irani, Al-Sebie & Elliman, 2006; Lappas & Yannas, 2006) describe the online stages an organization goes through time, becoming more mature in using the Web for providing better services to citizens. The maturity stages start from the organization's first attempt to be online aiming at publishing useful citizens' information and move to higher maturity stages of being interactive, making transactions and finally transforming the functionality of the organization to operate their business and services electronically through the Web. But, maturity stages described in literature do not have a Web mining dimension, which the author considers that should be the climax in maturity stages.

Riedl (2003) states that by using interviews and Web mining the actual access to information by citizens should be tracked, analyzed and used for the redesign of e-government information services. E-Government literature reveals that only recently Web mining has attracted researchers in e-government applications. Fang and Sheng (2005) present a Web mining approach for designing better Web portal for e-government. Hong and Lee (2005) propose an intelligent Web information system of government based on Web usage mining to help disadvantaged users make good decisions-making for their profit improvements. In the health sector, Mayer, Karkaletsis, Stamatakis, Leis, Villarroel, and Thomeczek (2006) investigate improvements of health services by quality labelling of medical

Web content in the recently announced MedIEQ project. Conclusively, e-government aim to improve government's services to citizens and any improvement to this direction lead to valuable implications of Web mining and machine learning to national and local societies.

E-Politics and E-Democracy

E-politics provides political information and politics "*on demand*" to the citizens by improving the political transparency and democracy, benefiting parties, candidates, citizens and the society. Election campaigners, parties, members of parliament, and members of local governments on the Web are part of e-politics. Despite the importance of e-politics in democracy there is limited Web mining methods to meet citizen needs. The author has identified in the literature research that only refers in mining political social networks on the Web. Link analysis has been used to estimate the size of political Web graphs (Ackland, 2005), to map political parties network on the Web (Ackland & Gibson, 2004) and to investigate the U.S. political Blogosphere (Ackland, 2005b). Political Web linking is also studied by Foot et al. (2003) during the U.S. congressional election campaign season on the Web. In this aspect, expanding e-democracy boarders will lead to more transparent and participating democracy, which are vital to the society.

FUTURE TRENDS

Nowadays the Web is a rich and huge information repository, where a number of methods and automatic systems have been created for identifying, locating, accessing, and retrieving information. The main open question in Web mining is how to provide information relevant to specific users' needs. Semantic Web (Berners-Lee et al., 2001) works toward this direction and is considered as the next Web generation. The current Web is based on the hypertext mark-up language (HTML), which specifies how to layout Web pages so that they can be readable to humans, thus it is human-centralized. The problem is the retrieval of relevant information by search engines because machines cannot understand Web content to retrieve relevant information. This is expected to change by semantic Web technologies as in semantic Web "information is given well-defined meaning better enabling computer and people to work in cooperation" (Berners-Lee et al., 2001).

Consequently, machine-learning techniques will continue to play the most important role in the semantic Web (Hess & Kushmerick, 2004) for information retrieval and knowledge discovery. Berendt et al. (2002) introduce "semantic Web mining" as the field where semantic Web meets Web mining. It is expected that machine learning techniques and semantic Web mining will be in the focus of research for the next years.

In this chapter the author has introduced areas of societal interest that may be benefited by Web mining and machine learning. The literature review revealed that most research in these areas has just recently been started. The future trend seems to be the convergence of Web mining and machine learning to practical solutions in the six areas of societal benefit: Helpdesks and recommendation systems, digital libraries, e-learning, security and crime investigation, e-government services, e-politics and e-democracy.

CONCLUSION

This chapter has provided a survey on Web mining and machine-learning methods focusing on current Web mining research in societal benefit areas identifying that most of this research has been recently developed. Therefore, one of the current trends of Web mining is toward the connection between intelligent Web services and applications of social benefits, which brings to work closer scientists from various disciplines.

Furthermore, this integrating tendency benefits researchers from various fields.

Social studies on the Web may benefit from machine learning and Web mining methods for providing them with tools and methods to better collect, manage and analyze Web based-phenomena. Moreover, a social interpretation of the meaning of outcomes from computer science Web mining methods is the key question from social and communications studies (Thelwall, 2006). Finally, Web mining and machine learning community may benefit from social and communication expertise on the Web to better interpret their outcomes in the direction of why this happens; or whether mining patterns have meaningful or useful knowledge; or whether hidden knowledge found from Web mining creates a new view that needs further investigation and explanation.

Chapter 5.18
Toward Mobile Web 2.0-Based Business Methods:
Collaborative QoS-Information Sharing for Mobile Service Users

ABSTRACT

Mobile service providers (MoSPs) emerge, driven by the ubiquitous availability of mobile devices and wireless communication infrastructures. MoSPs' customers satisfaction and consequently their revenues, largely depend on the quality of service (QoS) provided by wireless network providers (WNPs) available at a particular location-time to support a mobile service delivery. This chapter presents a novel method for the MoSP's QoS-assurance business process. The method incorporates a location- and time-based QoS-predictions' service, facilitating the WNP's selection. The authors explore different business cases for the service deployment. Particularly, they introduce and analyze business viability of QoSIS.net, an enterprise that can provide the QoS-predictions service to MoSPs, Mobile Network Operators (as MoSPs), or directly to their customers (i.e. in B2B/B2C settings). QoSIS.net provides its service based on collaborative-sharing of QoS-information by its users. The authors argue that this service can improve the MoSP's QoS-assurance process and consequently may increase its revenues, while creating revenues for QoSIS.net.

INTRODUCTION

The last 15 years have been marked by the expansion, global adoption and seamless availability of the (fixed) Internet with a multitude of its ubiquitous services. In parallel, a new mobile era has undergone its preparation phase, driven by miniaturization and personalization of communication devices, as well as the rapid expansion and adoption of mobile voice and data services and heterogeneous communication infrastructures (Hansmann *et al.*, 2003).

In this era, ubiquitous Mobile Service Providers (*MoSPs)* bring to the market users' favorite Internet-services and start offering a wide range of new services. As a *mobile service* we define a data service that is delivered to (or from) a mobile device from (or to) the Internet. The service delivery is supported by the deployment of wireless communication infrastructures, enabling a user the Internet-connectivity while on the move. A MoSP is then an enterprise, which core business processes aim at providing mobile services to its customers (TMF, 2001).

The MoSPs are fully aware that to achieve their goals of gaining customer acceptance, secure their revenues and remain competitive, their services must provide users *Quality of Experience* (QoE) comparable to the QoE provided by the existing Internet-services (Afuah & Tucci, 2000). The QoE is "the overall acceptability of service, as perceived *subjectively* by the user" (ITU-T, 2007), and as a part of it, a MoSP must at least assure meeting user's *Quality of Service* (QoS) requirements, expressed quantitatively in terms of service speed, accuracy, dependability, security level and price related (performance) measures. The QoS is defined as "a collective effect of service performances which determine the (*objective*) degree of satisfaction of a user" (ITU-T, 1993). MoSPs unanimously indicate, that their *QoS-assurance process*, i.e., a business process related to service-management, and responsible for assurance that services provided to users are performing according to their QoS-requirement, is critical to their business viability (Andersson *et al.*, 2006; Nokia, 2004).

The challenge is that, the MoSPs' QoS-assurance process relies on the QoS provided by wireless communication infrastructures, supporting the mobile services delivery. Ideally, there would be infrastructures supporting anytime-anywhere services delivery to a user. However, in reality these infrastructures are beyond the control of MoSPs; they are owned and managed by enterprises called *Wireless Network Providers* (*WNPs*). A WNP core business processes aim at providing Internet-connectivity to its customers. A wireless communication infrastructure exhibits different QoS depending on the WNP it's owned by, a wireless technology used (e.g. WLAN/GPRS) as well as the mobile user's location-time.

Nowadays, in most countries, a number of WNPs coexist, operating different long-range wireless communication technologies. In particular, there exists at least one nationwide WNP called a *Mobile Network Operator (MNO)*. A MNO is an enterprise that, as a WNP, owns and manages its wireless network infrastructures. MNO's core business processes aim at providing voice services (primarily) and Internet-connectivity, using long-range wireless technologies (e.g. GSM/UMTS) (ITU, 2005) to its customers. A MNO can take a role of a MoSP, i.e., can also provide mobile services to its customers.

In parallel, WNPs like public-WLAN providers emerge rapidly, especially in big cities. Moreover, today's mobile devices embed multiple interfaces, thus supporting Internet-connectivity over various wireless technologies. Hence, the communications means tend to be ubiquitously available to mobile service users, and, at least in principle, these users must be able to choose a WNP (and a wireless technology) providing the QoS best meeting their QoS requirements thus facilitating meeting their expected-QoE. However, this assumption is far from the reality. The business strategy of existing WNPs, and particularly

MNOs, is based on a user 'lock-in', i.e., the user can access only wireless networks owned by 'his' WNP (Buschken, 2004). Moreover, the only disclosed information about the QoS provided by WNPs is based on the WNPs' marketing data about their network's theoretical performance—the real QoS (i.e. objectively measured) is unknown to the mobile users. Even mobile services provided by MNOs (taking a role of MoSPs), are based on estimations regarding their provided-QoS. A likely cause is the limited time/budget spent on service-user trials by MNOs (Tan, 2004). Moreover, it is widely accepted that performance tests conduced by WNPs, and particularly by MNOs, are coarse-grained 'drive-tests' over main streets in big cities and main highways (Gomez & Sanchez, 2005). These tests prove the availability of MNOs networks, i.e. their coverage at different locations; and the results are disclosed to a public as coverage maps. Current practices continue, despite the fact that the network's provided-QoS and user perceived-QoE are identified as one of the major factors for customers' loyalty, and moreover, a 'lock-in' practice is admitted to fail as a long-term strategy for customers' retention (Gerpott *et al.*, 2001; M.I.S Trend S.A., 2007; Nokia, 2004).

Effectively, WNPs networks provide 'best-effort' service quality-level to MoSPs. Additionally, MoSPs cannot select at a certain location-time a WNP, which provides a QoS that best meets their customer's required-QoS and their expected-QoE. MoSPs are constrained by the above situation and can only provide mobile services to their customers at a 'best-effort' QoS-level.

We envision that the above mobile user's restrictions on a WNP selection will be removed in the future. Already we see a role of *Mobile Virtual Network Operator (MVNO)* appearing on the market. A MVNO is a WNP (and particularly a MNO) providing voice services and Internet-connectivity over wireless network infrastructures owned/managed by multiple WNPs/MNOs (i.e. MVNO has business contracts with these WNPs/MNOs to resell a use of their infrastructures). A MVNO's customer, i.e., a mobile user can therefore have an Internet-connectivity via set of network infrastructures. With larger number of WNPs/MNOs, with which a MVNO has a contract, a larger WNP/MNO choice becomes available to a mobile user at any location-time. However, this does not solve the problem of how the user will choose the most appropriate WNP/MNO, given his location-time, QoS-requirements and QoE-expectations.

As a solution, we firstly propose a novel *method* facilitating QoS-assurance business process of MoSPs. As a novel method we define a (business) method employed in an enterprise's business process(es), innovative in terms of technology and/or business contracts established between enterprises in a service-value chain (TMF, 2004).

Our method is technologically innovative because it incorporates fine-grained location-time-based predictions about the QoS-observed when given WNP is used, into the MoSP's QoS-assurance process. These predictions are denoted as *QoS-predictions*. They can be used to select a WNP (and a wireless technology) best meeting MoSP's user QoS-requirements. The goal of the proposed method is to facilitate MoSPs' to meet user's expected-QoE and thus increase own revenues. This follows the observation that a happy MoSP user is willing to continue using the service and paying for it (Andersson et al., 2006).

Our method is also innovative for a MoSP in terms of its business contracts. Namely we envision that there is a separate enterprise—a provider of the QoS-predictions (service), called *QoSIS.net*. QoSIS stands from *Quality-of-Service Information Service* embracing the QoS-predictions as part of its service. A MoSP has business relation with QoSIS.net in order to use the QoS-predictions.

Besides a novel method for a MoSP, we also propose a novel method for QoSIS.net. This method facilitates its core business process, i.e. a QoS-predictions service-fulfillment related process, embracing development and operation of the service, as requested by its customers (TMF, 2001).

The method proposed for QoIS.net is innovative technologically because it is based on user collaborative QoS-information sharing; QoS-information is acquired when mobile service users use different WNPs at different locations-times. The method's key feature is that QoSIS.net can provide accurate QoS-predictions only after having a large volume of historical QoS-information acquired from mobile users. Currently, we conduct the QoS-predictions feasibility assessment (including accuracy evaluation) in the mobile healthcare domain (Wac *et al.*, 2008).

To be more specific, QoSIS.net provides mobile service users (as a community) with QoS-predictions, as a value-added service. On behalf of these users, QoSIS.net exchanges between them the QoS-information about QoS observed when using different WNPs. This follows an idea behind all emerging *Web 2.0* services that gain an increasing users' acceptance in different domains (e.g. Facebook, Wikipedia) (Hoegg *et al.*, 2006; Martignoni & Stanoevska-Slabeva, 2007; Pascu *et al.*, 2005). Web 2.0 is a paradigm for "mutually maximizing collective knowledge and added-value for each *participant* (in a community) by formalized and dynamic sharing and creation of user-generated content" (O'Reilly, 2005). Its 'mobile' extension implies an implementation of Web 2.0 service as a mobile service. QoSIS.net, as a provider of QoS-predictions, based on QoS-information acquired from mobile users, adheres to a Mobile Web 2.0 paradigm. QoSIS.net customers are such 'participants' (also called 'prosumers' (Tapscott & Williams, 2006)) contributing to the community with their QoS-information.

In this chapter, the business viability of QoSIS.net is examined in detail, and it discusses possible technical solutions supporting QoS-predictions service fulfillment. We argue that the methods proposed for MoSPs and QoSIS.net have a strong potential to bring benefit to them in terms of revenue creation and customer satisfaction. Therefore, in the next sections we present current solutions for QoS-assurance process of MoSPs, then we present our approach for and the results of- QoSIS.net business viability study, after which we present our vision for MoSPs' QoS-assurance process.

Current Trends

Internet was since its beginning, providing a 'best-effort' QoS-level. In the late 90's, first solutions for Internet-based SPs QoS-assurance business processes have been proposed, particularly for providers of real-time multimedia services (Shepherd *et al.*, 1996) (Hutchison *et al.*, 1997). From the technical perspective, these solutions were based on use of rigorous and complex QoS-management frameworks, including functions like QoS-negotiation and resource reservation (Andersen *et al.*, 2000; Xiao & Ni, 1999). Moreover, from the business perspective, these solutions required business contracts between SPs and Internet-providers (Afuah & Tucci, 2000). They contradicted with the 'open' nature of Internet-services, because they limited the SPs customer-base to that of the Internet-provider's base. In this situation, many SPs ignored the proposed solutions and learned to manage 'best-effort' QoS-level provided by Internet to assure meeting the QoS-requirements (and the expected-QoE) of their service users. The methods, employed in SP's QoS-assurance process, relied on estimations of QoS-provided by the Internet. This approach was feasible due to at least two factors: firstly, QoS-provided by Internet exhibits regularities and long-term estimations for e.g. months can be derived relatively accurately (claffy *et al.*, 1998). Secondly, if necessary, SPs could easily acquire information on provided-QoS via dedicated QoS-monitoring and all that without any degradation in the quality of their provided services (Michaut & Lepage, 2005).

With the dawn of the mobile era, history is repeating itself. The QoS-assurance process has been identified as critical to the business viability of MoSPs already in the late 90's (Chalmers & Sloman, 1999), when only basic voice and data services existed. The most critical factor in QoS-assurance is related to the user's mobility: a mobile user relies on the availability of different WNP/wireless technologies at different locations-times along his trajectory (Dekleva *et al.*, 2007). To deal with this, MoSPs are (again) advised to employ complex QoS-management frameworks in their QoS-assurance business processes. This solution (again) requires a close business relationship between MoSPs and WNPs, resulting in a WNP-centric business models. This solution is explored in research (Calvo *et al.*, 2004; Faber *et al.*, 2003; Robles *et al.*, 2002; Tan, 2004; Tsalgatidou & Pitoura, 2001).

From a technological perspective there are also other proposals. For example a proposal for MoSPs QoS-assurance process to employ predictions of user mobility path acquired from a WNP (Han & Venkatasubramanian, 2006; Soh & Kim, 2003), or to employ a QoS-broker for the reservation of WNP's network resources on behalf of MoSPs users (Nahrstedt *et al.*, 2001). Simultaneously, MNOs propose new concepts like Universal Mobile Access, Generic Access Network or IP-Multimedia-System (Cuevas *et al.*, 2006), aiming at a technical as well as a business solutions for MoSP's QoS-assurance process; aiming for MoSPs to have their core business processes tightly coupled with the business processes of MNOs. Such solutions contradict the 'mobile' nature of MoSPs' services, because business relations with MNOs limit MoSPs customer base and service-usage area to the MNOs customer-base and its coverage-area.

The MoSPs not following the WNP-centric business models emerge on a growing scale (Tan, 2004). Naming few, Skype is a VoIP provider (Osterwalder *et al.*, 2005), MobiHealth.com is a mobile healthcare SP (MobiHealth, 2007), while Digital Chocolate is a mobile gaming SP (Digital Chocolate, 2008). They all struggle to assure meeting their mobile users' QoS-requirements over unpredictable 'best-effort' QoS-provided by WNPs/wireless technologies (Bults *et al.*, 2005). Dedicated QoS-monitoring is not feasible due to the dynamic nature of QoS-provided by WNPs/wireless technologies (Dood, 2005) and the limited resources (e.g. battery) of mobile devices.

At the same time, new WNPs appear and new long-range wireless technologies (e.g. Ultra-Mobile-Wideband) are deployed by the existing WNPs. These are steps towards the vision of 4G, where wireless communication infrastructures are going to be plentifully available for mobile service users (De Vriendt *et al.*, 2002; Dekleva et al., 2007; Ortiz, 2007; Tachikawa, 2003). Yet, any new WNP or wireless technology when launched provides only a 'best-effort' QoS-level (Gomez & Sanchez, 2005) and uses the 'drive-tests' as performance tests.

A new trend of user-centric business models is arising in a mobile business research (Dekleva et al., 2007), aiming in the situation where a MoSP and its mobile service user can access any WNP anytime-anywhere. Towards this end, some technological solutions are proposed for signaling for inter-WNPs handover (Bless *et al.*, 2004; ITU-T, 2006) or for QoS-negotiations between a mobile device and a WNP (Manner *et al.*, 2001). From the business contractual perspective, an idea of 'ad-hoc' smart-business networks (van Heck & Vervest, 2007) between WNPs and MoSPs supporting delivery of service to a mobile user has been presented, while research in large EU projects focus on new methods for MNOs to support MoSPs, without locking-in the MoSPs' customers (Sanchez *et al.*, 2008). Still the question remains: how a MoSP chooses a WNP best matching his user's QoS-requirements and QoE-expectations at a given location-time. To the best of our knowledge, the kind of solution we propose has not yet been proposed in the literature.

Research Goals and Approach

The goal of this chapter is to analyze the business viability of the methods proposed for MoSPs and QoSIS.net. Our approach is as follows. The first step is the choice of the MCM-Business Model Framework of Hoegg et al. for analysis of QoSIS.net as an example of enterprise employing the Mobile Web 2.0 paradigm.

The MCM framework was initially based on a well-established definition of a *business model* being "1) an architecture for the products, services, information flows, including a description of various business actors and their roles, 2) a description of the potential benefits for the various business actors, and 3)a description of the sources of revenues" (Timmers, 1998). Furthermore, Hoegg et al. enhanced this definition to include a social environment component, and that based on examining the other existing frameworks being applied to the existing MoSPs (e.g. 'MediAlert' SP). Along this research they conducted surveys and interviews with mobile service users and domain experts. Finally, the framework presented by them in 2005 (Hoegg & Stanoevska-Slabeva, 2005), has been later-on successfully employed in analysis of existing businesses by other researchers, and in an analysis of (Mobile) Web 2.0 businesses conducted by the authors themselves (Hoegg et al., 2006; Martignoni & Stanoevska-Slabeva, 2007).

The second step of our approach is to apply this framework and conduct QoSIS.net business viability analysis. Particularly because the QoSIS.net is a non-existing enterprise, we conduct this analysis based on the intended QoS-predictions service usage scenarios. Therefore in the following paragraphs we provide the details of the framework, then the QoSIS.net usage scenario, and then its business viability analysis along the framework.

The MCM-Business Model Framework

The MCM-business model framework can be applied for a business viability of a MoSP, and particularly for an enterprise providing (Mobile) Web 2.0-services. The framework has the following components, that collectively expose enterprise's business model and factors influencing its design (Hoegg & Stanoevska-Slabeva, 2005), see also Figure 1:

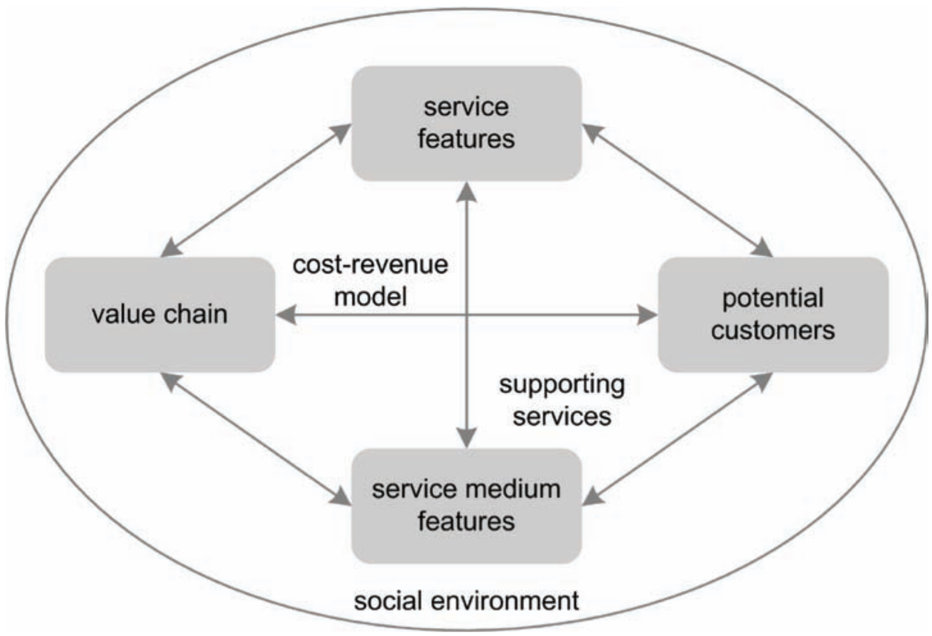
- **Features of the service:** Design and operation of the service provided by an enterprise to its customers (i.e. the enterprise product)
- **Potential customers:** Aspects of target groups of customers (i.e. market segments) and expected service's value-added for them
- **Value chain:** Players involved in delivery of the provided service and their interrelations
- **Cost-revenue model*:*** Financial model explaining contribution of players in value chain
- **Features of the service medium:** Characteristics of means with which service is delivered and that may influence service interactions (e.g. service can be mobile)
- **Flow of supporting services:** Necessary for delivery of the service provided to customers
- **Social environment:** External influences—social, ethical aspects influencing the way the business is designed, implemented and operated.

QoSIS.net Viability Analysis

User Scenario

As every Saturday, Sophie, Maria and Eric meet in Westfield-London shopping center. Sophie is a young COPD (chronic obstructive pulmonary disease) patient and her health state is continuously monitored from the hospital with the MobiHealth's COPD Body-Area-Network (BAN) that she is wearing. She does not have to visit a care professional at the hospital frequently, she feels secure

Figure 1. MCM-business model framework



being remotely monitored. She is less restricted in her active life; she enjoys Saturday's habit of meeting her friends. In case of exacerbations, help from the hospital is dispatched to her, wherever she is. In the mall, her COPD BAN always uses the most suitable WNP/wireless technology as available there. The "*most suitable*" means sending her vital-signs data at the highest speed, i.e. with the lowest possible delay, to the hospital, and in a secure manner (i.e. not using unknown free WLANs). Netwrok usage price does not matter. The WNP/wireless technology selection process is transparent to her. In the mall her BAN uses most of the time the 3G-HSUPA network of Vodafone-UK, and when it is not available, e.g. inside the big shops, the BAN switches to 3G-UMTS network of T-Mobile. In such a way her service-data is always sent at the highest possible speed to the hospital.

Maria and Eric are both typical technology nerds competing with each other. Maria has a newest mobile from 3UK with this fancy SeeMeTV application, which allows her to easily post short videos from her mobile on the SeeMeTV-web. She enjoys making jokes with Sophie and Eric, trying to get some catchy video that can bring her money if other SeeMeTV users watch it or even a prize of £1000 if they vote for it. To access the SeeMeTV-web her mobile always uses the most suitable wireless technology of 3UK, as available in this center. For her, the most suitable means that her videos appear online as quick as possible; price does not matter much to her; she can afford it. This time her mobile uses the 3G-UMTS network, because 3UK's GSM/GPRS network is, as always on Saturdays, saturated with voice/SMS traffic of users shopping in the same center.

Eric is a Facebook fan, and uses this social-networking community to stay in touch with his family and friends back home in Amsterdam. He also enjoys making funny photos and movies along their day and posts them to his blog. He has just bought a fancy t-shirt for his brother, and he has posted a related movie and is now waiting for response—maybe it is not what his brother wanted? To access Facebook, his mobile always chooses the most suitable WNP/wireless technology available in the mall (in his case the cheapest but still as fast as possible!). Because he uses the latest phone with an integrated GPS, he was able to download an application from QoSIS.net website. This little application makes the WNP/wireless technology choice on his behalf; he just needed to set his selection preferences. Since he installed it, he is very satisfied using his Facebook.com services which are provided to him without frustrating connection loses, as it was the case in the past. During this shopping-day, his mobile uses 2.5G-GPRS of O2 in the morning, and Orange-WLAN network in the afternoon, as they moved to the north part of this big center, where it has become available to him.

Features of the Service

The QoS-predictions service is a mobile service that provides MoSP and their users with fine-grained location-time-based QoS-predictions, about QoS-provided by different WNPs/wireless technologies at a given location-time. Each QoS-prediction is an estimation of QoS-provided by a WNP/wireless technology at a given location and time in the future, associated with its accuracy value.

The QoS-predictions service is a value-added service for MoSPs and their users. It is used by a MoSP in a WNP/wireless technology selection process; but it is transparent for a MoSP user like Sophie, Maria or Eric (the only effect a MoSP user may see is a changing WNP name on his/her device screen as an effect of a vertical handover of his mobile-device between different WNPs).

Although it was not shown in the QoSIS.net user scenario, the QoS-predictions service based on the user's private mobility-map (stored on the user's mobile device) denoting nearby locations along with QoS-predictions for these locations in different times. The mobility-map is automatically updated, either at regular time-intervals or at the moment a new QoS-prediction is requested. The information in the map allows the mobile service user to get QoS-predictions even if the user is out of coverage of any WNP (although these QoS-predictions can be outdated depending when the map was last updated); in this situation a user can see where is the closest WNP available for him and what is its predicted QoS. If a service provided by a MoSP is critical, e.g. a MoSP is MobiHealth providing mobile healthcare service, the user can be warned explicitly via sound/vibration generated by the mobile device, when he a leaves the coverage area of any WNP.

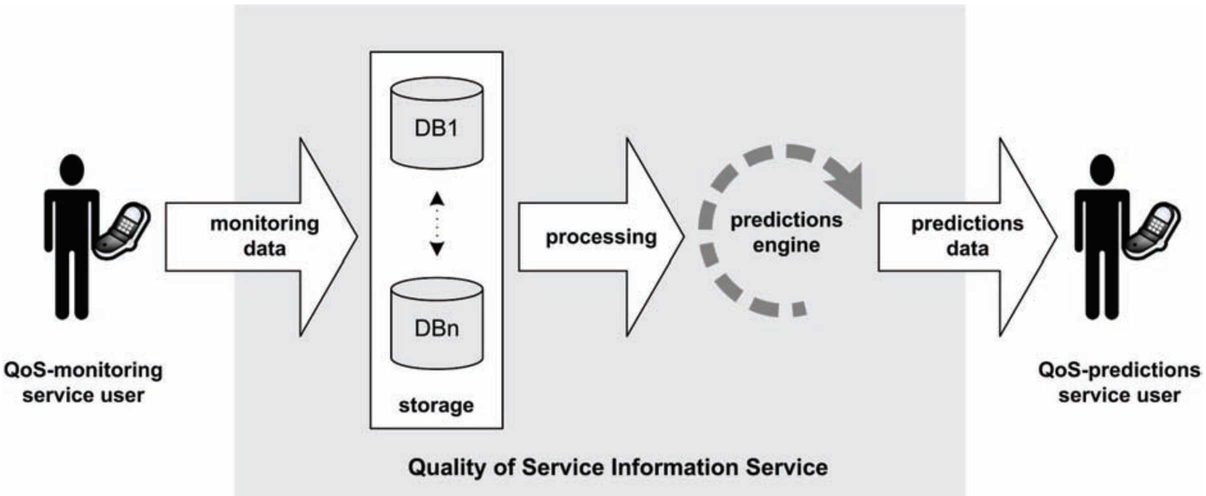
The QoSIS.net operation is based on the QoS-information service; QoS-predictions service is part of it. The QoS-predictions service is based on users' collaborative QoS-information sharing, i.e. information is acquired from MoSPs users using different WNPs/wireless technologies at different locations-times. The collected QoS-information is used to derive QoS-predictions, used (back) by mobile users. The QoS-predictions are then validated along the new collected QoS-information; a feedback is implemented implicitly. Therefore, the QoS-information service contains of (Figure 2):

1. QoS-monitoring service
2. QoS-information processing service and
3. QoS-predictions engine (Pawar *et al.*, 2008; Wac, 2006).

Particularly, QoS-monitoring and QoS-prediction services are executed partially on a mobile device of the service user (see further paragraphs for details).

The *QoS-monitoring service* acquires QoS-information from mobile users (and actually from their devices) based on application-level measurements, i.e., measurements of the mobile service's observed QoS as well as users location-time and other parameters (see further details). Technically, QoS-monitoring service can be realized via passive QoS-measurements in MobiHealth or SeeMeTV service for users like Sophie and Maria, or via measurement-applications like AcbTaskMan

Figure 2. QoSIS.net high-level system architecture



(AcbTaskMan, 2007) or CoSphere (Peddemors, 2008) for Facebook users like Eric.

The QoS-monitoring service is transparent to the MoSP's users. The QoS-information is acquired to QoSIS.net, preferably via a lightweight protocol. The information is send with an hourly or daily frequency or even continuously (however that can be exhausting for mobile device resources). The information can be compressed (using lossless algorithms) before being send to the QoSIS.net, where is stored in databases (DBs).

The quality of the acquired QoS-information is critical to the accuracy of the QoS-predictions' service (and hence to QoSIS.net business viability). We argue, that the QoS-predictions' service cannot be more accurate than the historical QoS-information it is based upon. Particularly the location-time accuracy is critical; a user moving few meters away may observe a different QoS for a given WNP/wireless technology and hence acquire different QoS-monitoring data (Dood, 2005).The QoS-information acquired from MoSPs users includes:

1. the mobile user's location-time, mobility level (e.g. fixed location, walking, moving in a vehicle)
2. the WNP name and wireless technology used
3. the network usage price and security level
4. the mobile service's speed in terms of delay/throughput/loss (ITU-T, 1993, 2006; Seitz, 2003); detailed metrics depend upon the mobile service for which QoS-predictions are provided
5. the characteristics of the mobile device (CPU, memory, battery, network interfaces) and the location-determination system type/accuracy e.g. GPS system

The QoS-information does not have (nor needs) any notion of the mobile user's identity, all information acquired from mobile users is anonymous (but needs to be trustworthy).

The *QoS-processing service* (presented as an arrow in the figure) transforms the stored QoS-information into a form suitable for a QoS-predictions' engine. The transformation may include annotation, rating, sub-sampling, discretization, obfuscation or any other method for information processing commonly used in data mining techniques (Mitchell, 1999).

The *QoS-prediction engine* continuously processes large quantities of collected historical QoS-information. The engine uses data mining techniques (e.g. Bayesian Networks or trees (Witten & Frank, 2005)) to discover QoS-information patterns. A QoS-prediction service request retrieves instantaneously the requested QoS-predictions for a given location-time. The result is returned to the QoSIS.net customer (i.e. a MoSP service user) in form of mobility-maps.

One of the mobile service users' characteristics, which we envision can facilitate QoS-predictions accuracy, is the fact that these users tend to have fixed mobility patterns, e.g. home, work, shopping-center at particular week-days on particular hours. Scientific research indicates that 45% of the people stay in a location area of a radius of ~10 km, while 73%—of radius of ~30 km and their mobility patterns can be learned for a history of 3 months (Gonzalez *et al.*, 2008). We anticipate that if the user's mobility pattern is highly predictable, a collection of large amount of QoS-information for WNPs/wireless technologies available to this a user along his movements, facilitates providing accurate QoS-predictions to this user.

Features of the Service vs. Mobile Web 2.0 Paradigm

The QoS-predictions' service is based on users-collaborative QoS-information creation and sharing. Hence, QoSIS.net can be seen as a specific example of *stand-alone Mobile Web 2.0 Service Provider* (Hoegg et al., 2006; O'Reilly, 2005). The content produced by MoSPs users is the QoS-information acquired by the QoS-monitoring service. This content is then processed in QoS-predictions engine and it is consumed by mobile users via the QoS-predictions service. Mobile users are content 'prosumers' (Tapscott & Williams, 2006). We argue that while implementing the QoS-predictions service as Mobile Web 2.0, where users collaboratively collect QoS-information, QoSIS.net may benefit from the fact that MoSPs' users are very likely to be in a close location-time span, e.g. in one city, and therefore they collect overlapping QoS-information, which in turn increases the QoS-predictions service accuracy.

Potential Customers

The QoSIS.net market contains two types of customers:

1. customers in a Business-to-Business market segment, containing MoSPs and WNPs/MNOs/MVNOs acting as MoSPs and
2. customers in a Business-to-Customer market segment containing mobile service end-users (i.e. customers of MoSPs).

Recalling that in our scenario, Sophie is a MobiHealth.com customer and a user of its mobile health monitoring service. MobiHealth.com is an example MoSP (van Halteren *et al.*, 2004). Maria is a MNO-3UK customer and SeeMeTV mobile service user; her MNO acts as a MoSP (3UK, 2008). Sophie and Maria have role of QoSIS.net service users. Eric is a Facebook.com (MoSP (Facebook, 2007)) customer and user, and a customer and user of QoSIS.net.

Business-to-Business (B2B)

MoSPs like MobiHealth.com or MNOs like 3UK are potential business customers of QoSIS.net. They are particular mobile service providers in e.g. mobile information, healthcare or entertainment domains. Services provided by these types of MoSP require frequent exchange of service-data between (Internet-based) servers and mobile users and hence frequent use of WNPs. Mobile user's satisfaction depends on the QoS-provided by the WNP used for service delivery. For MoSP, QoS-predictions can be used in a WNP/wireless technology selection process. For a MNO acting as a MoSP, QoS-predictions can be used in a selection process of a wireless technology (WLAN/GPRS/UMTS/HSxPA) at a given location-time for a mobile service user. The goal of MoSPs is to best meet users' QoS-requirements and facilitate meeting their expected-QoE. QoSIS.net can play an instrumental role in meeting this goal.

The QoSIS.net fulfills the MoSP's need of knowledge of QoS-provided by different WNPs/wireless technologies at mobile user location-time. For a MNO, it adds to its existing coarse-grained knowledge of its network; a MNO can analyze its provided-QoS to mobile service users at given locations-time and be willing to improve this QoS in order to stay competitive amongst the WNPs. The QoS-information can support the MNO's network planning, dimensioning and management, as well as better design of own mobile services provided to mobile users. Moreover, once encouraged, a WNP can even provide QoSIS.net with some additional information regarding its network configuration, which would facilitate more accurate QoS-predictions service. Without the existence of the QoSIS.net, MoSPs/MNOs try to assure QoS to its users by using coarse-level QoS-estimations (c.f. Current Trends). The advantage for QoSIS.net of entering in a business relation with a MoSP would be that they can be an equal copartner in designing the QoS-predictions and QoS-monitoring services (e.g. mobile device configuration), have integrated billing for both services, co-marketing and co-branding strategies, bringing even more customers to the MoSP.

When using QoS-predictions, a MoSP better manages user's resources involved in its services delivery e.g. lower service-data delays/improved throughput or optimizing user's device battery life. The biggest incentive for a MoSP to use QoSIS.net would be the fact that by using QoSIS.net, it can increase its customers' satisfaction and hence its revenues.

Although it sounds contradictory to what we have said earlier, we claim that MoSPs and particularly MNOs can use QoSIS.net services as a way to additionally 'lock-in' its mobile service users to their services/networks. It is because a customer satisfaction and QoE is a strong predictor of customer loyalty (Eshghi *et al.*, 2007), and QoSIS.net facilitates its improvement. Namely, if users are satisfied from the services provided to them, and they experience them at the expected-QoE level, they are more likely to use even more services from this MoSP. Additionally, the cost of switching to other MoSP for this user can be high: new MoSP may not use QoSIS.net, and even if they do, the user's historical QoS-information might not be portable to this new MoSP. In this situation a user need to accept that only after some service-launch-time (necessary for collecting of historical QoS-information), the service will be provided to him at the expected-QoE level, bringing him back satisfaction related to the service use.

Business-to-Customer (B2C)

Mobile service users like Eric are potential customers of QoSIS.net, but only if they have a mobile device with localization capabilities, e.g. an integrated GPS. Because their QoE while using their mobile services is related to the QoS-provided by the WNP/wireless technology used, they are interested in the use of QoSIS.net's value-added service in order to facilitate (proactive and automatic) choice of the WNP/wireless technology that fits best to their needs anytime-anywhere. The user grants responsibility to the QoSIS.net on how to use QoS-predictions, i.e., when to demand new QoS-predictions and when to choose another WNP/wireless technology.

QoSIS.net can equally target mobile users living a village or city suburbs with limited WNP/wireless technologies choice, as well as big number of users living in the city center with plentiful of available WNPs/wireless technologies.

A QoSIS.net user saves resources involved in e.g. Facebook.com services delivery e.g. money while choosing a WNP with cheaper tariffs, or mobile device's battery life. The incentive for a mobile user to use QoSIS.net is the improvement of his QoE when using his mobile services. Without the existence of QoSIS.net, Eric would be using an arbitrary WNP/wireless technology as available in his location-time, probably experiencing lower quality services and paying more than he expects.

QoSIS.net's Critical Success Factors

We identify that a critical success factor for the QoSIS.net service is to reach a critical mass of QoS-predictions service users. This is because QoSIS.net business thrives on large quantities of QoS-information for its QoS-predictions service. We envision that the primary market segment is B2B, and the secondary is the B2C. The B2B market entry strategy is to convince MoSPs and MNOs that QoSIS.net adds an accurate fine-grained location-time-based QoS-predictions service to their infrastructure that facilitates the improvement of QoE of their customers, hence increases their own revenues. This way the QoSIS.net user-base will be then equal to MoSPs/MNOs customer base. However, the initial hurdle of getting enough historical QoS-information for accurate QoS-predictions remains. QoSIS.net needs to agree with its customers on service-launch-time duration, after which it will provide QoS-predictions service with a given accuracy. We envision that the service-launch-time will be a function of mobility patterns of mobile service users (c.f. discussion on QoS-predictions engine) (Gonzalez et al., 2008). Once the QoSIS.net B2B market is substantial enough (i.e. sufficient QoS-information is available for QoS-predictions), the B2C market can be targeted.

Value-Chain

Value chain of QoSIS.net is different for B2B and B2C market segments and is presented in the following paragraphs.

B2B

In the value chain for business relation between QoSIS.net and a MoSP we distinguish QoSIS.net, MoSP like MobiHealth.com, and a MoSP user—Sophie (Figure 3a), who is also a QoSIS.net user. MobiHealth.com can have a business relation with one or more different WNPs/MNOs (via a MVNO). For a relation between QoSIS.net and a MNO acting as a MoSP, we distinguish: QoSIS.net, MNO like 3UK (three.co.uk) and its SeeMeTV service user—Maria (Figure 3b), who is also a QoSIS.net user. In both cases QoSIS.net is a 3rd Party SP, i.e., value-added SP for MobiHealth.com and three.co.uk (QoSIS.net customers). They provide QoSIS.net services to their customers as an integrated offer; these services are transparent for Sophie and Maria.

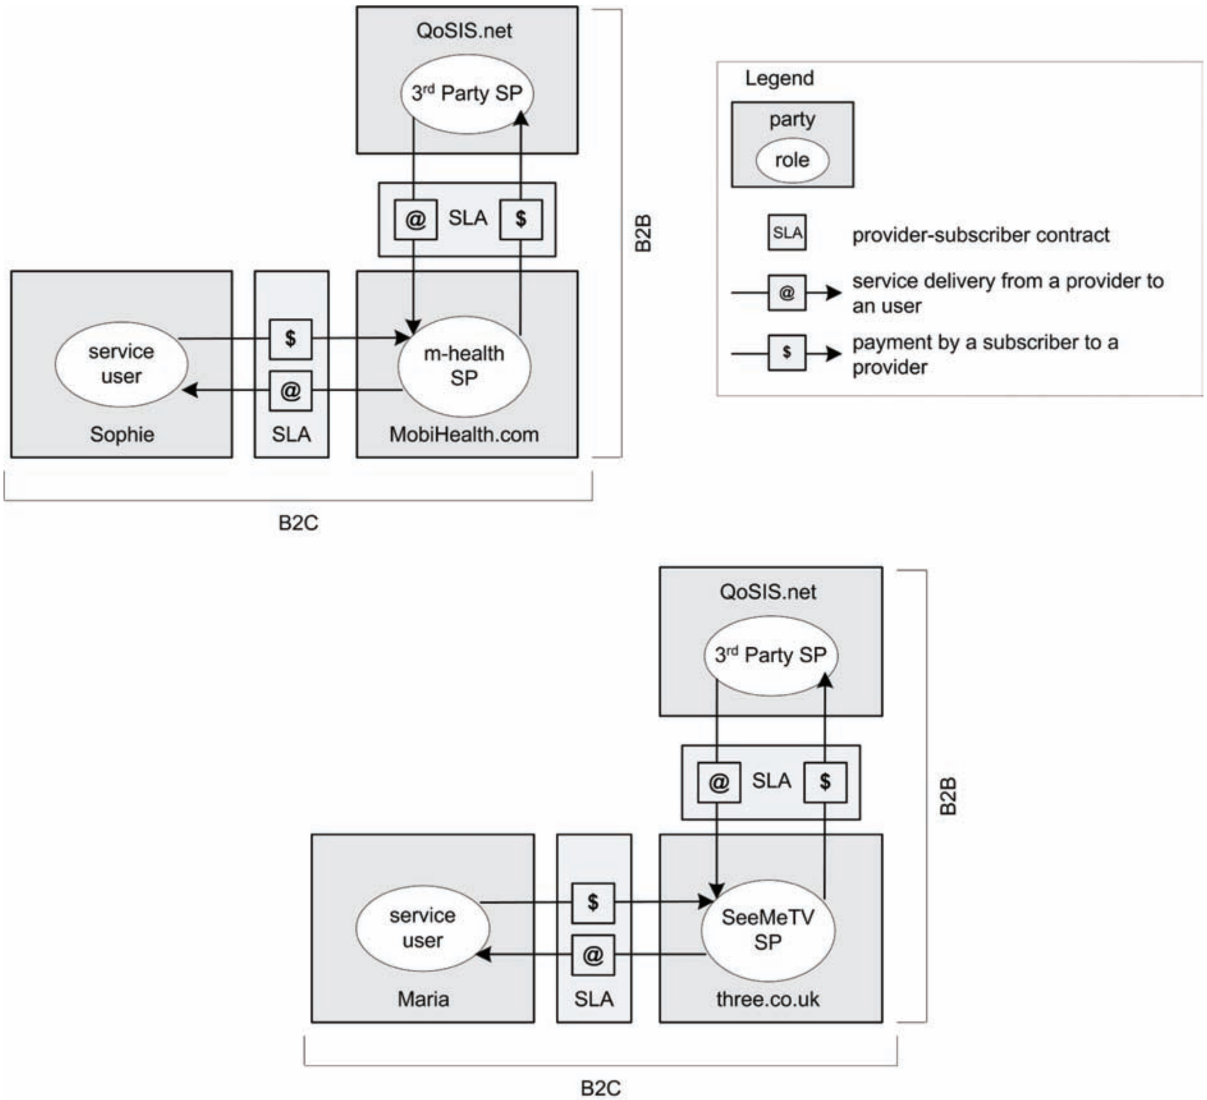
The *business relation* between QoSIS.net and MobiHealth.com/3UK is defined in a *contract* relationship. It is a negotiated and agreed between them formal document defining the terms and conditions for the delivery of the services (e.g. service availability of 99%), detailed services' usage specifications (e.g. user-pull or service-push) as well as the payment specifications (e.g. monthly, per-transaction post-paid) by MobiHealth.com and three.co.uk to QoSIS.net. this contract is also called a Service Level Agreement (SLA) (TMF, 2001).

Due to the nature of the service provided by QoSIS.net, a strong partnership trust (Ratnasingam & Phan, 2003) as well as technology trust (Ratnasingam *et al.*, 2002) is required between MobiHealth.com, 3UK and QoSIS.net in order to assure the success of all businesses. Critical technological details of QoS-monitoring and QoS-predictions service delivery need to be included in SLA, maybe even in legal terms, e.g. which enterprise is responsible if QoS-predictions are not accurate enough and Sophie finds herself outside any WNP at the moment she requires urgent medical assistance?

B2C

In the value chain for business relation between QoSIS.net and a MoSP user, we distinguish: QoSIS.net, Facebook.com and Facebook.com's user—Eric (Figure 4), who is also a QoSIS.net user. Eric can have a business relation with one or a more WNPs/MNOs (via a MVNO).

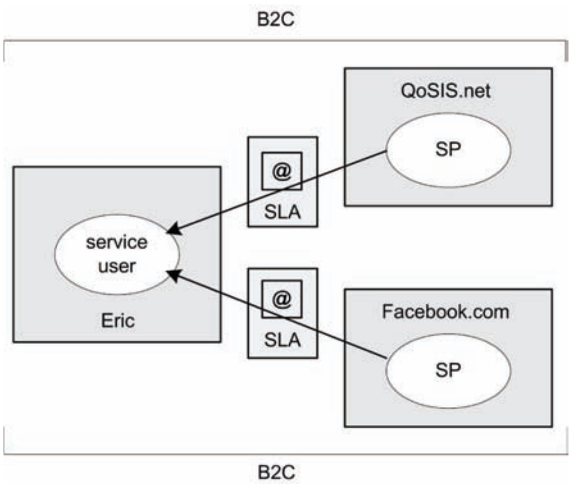
Figure 3. (a) Top QoSIS.net as 3rd party service provider for MobiHealth.com (a MoSP) 3b.on bottom QoSIS.net as 3rd party service provider for 3UK (a MNO in a role of a MoSP)



QoSIS.net is a value-added SP for Eric, and their business relation is defined by a SLA. The payment relationship with Eric states that QoSIS.net services are free (as his Facebook.com services). It is important to notice that the terms and conditions specified in this SLA need to be agreed upon by Eric, before the QoSIS.net application can be used by him, i.e. installed on his mobile device. Moreover, Eric is responsible to make sure that by using QoSIS.net he does not violate an existing SLA between him and Facebook.com, especially with regards to the (default) WNP use or use of any mobile device resources, for which these two SPs would now compete.

Facebook.com does not need to be in a business relationship with QoSIS.net, but it may benefit (in terms of revenues) from the services provided by it; satisfied Eric is more likely to use even more of Facebook.com services while on the move.

Figure 4. QoSIS.net as a service provider



Cost-Revenue Model

In B2B settings, QoSIS.net has costs related to the setup and maintenance of its services, and to the marketing aiming to get new MoSPs/WNPs as customers. QoSIS.net's customers have costs related to QoS-predictions service usage (as agreed in SLA). We argue that any reasonable pricing model proposed by QoSIS.net can be beneficial for QoSIS.net's revenues, increasing also the MoSPs/WNPs revenues, depending nevertheless on the MoSP's application area and criticality on QoSIS.net service to the MoSP's core business.

QoSIS.net customers in B2C settings do not pay for a service usage. In these settings, the QoSIS.net marketing costs are small, as the major advertisement policy is a "word-of-mouth" going from one mobile service user to another (Tapscott & Williams, 2006). QoSIS.net can also launch an affiliation program, rewarding mobile users who helped to acquire a new QoSIS.net customer via their website.Any QoSIS.net service user has costs:

1. Related to ownership of a mobile device with one or multiple network interfaces for wireless technologies like WLAN/GPRS/UMTS/HSxPA to be used via different WNPs (or at least one WNP) and an integrated location-determination e.g. GPS module
2. Related to the mobile device's resources: computation, storage and communication capacity, as well as its battery used for the service delivery.

We would like to emphasize that particularly in Europe devices manufacturers are committed to increase the number of mobile devices with integrated location-determination technologies, like GSM-cell triangulation or GPS. Nokia committed itself that by 2012 50% of its phones will have GPS-integrated (Nokia, 2004). In the US having these technologies in a mobile-phone is mandated due to 911 number and the location-identification requirements, while in Asia it is widely accepted as a new fancy technology. Market analysts predict that overall, by 2011, 29.6% of all mobile phones will have GPS (comparing to only 11.1% for 2006) (ABI Research, 2007).

Once QoSIS.net has reached a critical mass of customers, it can reconsider its cost-revenue model. For example, possible revenue for QoSIS.net can be generated by selling its QoS-information acquired in B2C-settings to MoSPs (like Facebook.com) or MNOs, or any other interested enterprises. It can mean selling (anonymized) user profiles and information about used mobile services.

QoSIS.net can also differentiate its prices for B2B and for B2C (introducing 'premium' service). The transaction fee can depend on:

1. The number of WNPs/wireless technologies available to a mobile user at a given location-time (i.e. the price increases with the number of WNPs/wireless technologies, because the richer the choice, the higher probability that a MoSP can use WNP/wireless technology matching its user QoS-requirements, thus improving its user's-QoE),
2. The actual accuracy of the QoS-predictions, where this accuracy can be checked against

the QoS-information acquired from user QoS-monitoring data
3. The accuracy of QoS-predictions, which would be (on purpose) lower for lower accuracy QoS-predictions, and higher for higher-accuracy QoS-predictions.

Service Medium

The QoSIS.net service is a mobile service—provided to its users from server on the Internet, accessible via a wireless medium. The features of this medium depend on WNPs/wireless technologies available at a particular location-time and used for QoS-predictions delivery. The QoSIS.net service may intentionally or accidentally be disabled/disturbed (Camponovo & Pigneur, 2003; Tsalgatidou & Pitoura, 2001), due to:

1. User communication-autonomy: (a) the user can deliberately configure his mobile device to use one particular WNP and wireless technology (b) user can be unreachable due to WNP lack-of-coverage or device's empty battery
2. Vulnerability of the user's mobile device (damage/loss) and its limited storage, processing, communication capabilities
3. WNP's wireless technology characteristics, e.g. asymmetrical throughput characteristics, variable delay characteristics and restrictions on volume of QoS-information exchange (hence lightweight protocols and lossless compression of exchanged QoS-information can be required).

Supporting Services

From a business perspective, all QoSIS.net's services: QoS-monitoring, QoS-processing and QoS-predictions services are necessary to create a value to the QoSIS.net's service user. Supporting processes include processes for a WNP/wireless technology selection (i.e. handover to) and its enforcement. A technical realization of intra- and inter-WNP (i.e. vertical) handovers is an ongoing research issue (Chen & Shu, 2005; Dekleva et al., 2007; Pawar et al., 2008), outside of the scope of this chapter.

From the QoSIS.net perspective, its web-service provided to customers like Eric is a service supporting acquisition of new customers in the B2C settings. Moreover, due to the nature of services delivered by QoSIS.net, business-partnership management is one of the supporting services but still in the core activities of QoSIS.net, e.g. for generating service reports for its customers.

Social Environment

There are several influences of the QoSIS.net services provision rising from customer competition, legislation and social/ethical constraints. Firstly, competition amongst QoSIS.net customers (MoSPs/WNPs) requires QoSIS.net to be a trustworthy enterprise. It should apply strong security mechanisms to prevent competitive customer information being disclosed to others. Any information regarding MoSP service usage statistics or its customer's profiles should be protected. Similarly, WNPs' competitive market situation poses strong security requirements on the QoSIS.net information. Any information regarding QoS provided by a WNP should not be altered in favor of this WNP. Moreover, in order to secure QoSIS.net revenues and its competitive advantage on the market, details of its QoS-information databases or QoS-predictions engine should not be disclosed to its customers.

An important social aspect of the provided service is related to the user-privacy consent. QoS-information acquired from QoSIS.net customers contains detailed location-time information of mobile service users. Therefore, it is required (at least in Europe) that a mobile service user is legally informed of the fact that this privacy sensitive information is acquired (Gorlach *et al.*, 2004), even if it is in anonymous form. In the B2B case, it is the responsibility of a MoSP as the QoSIS.net customer to provide user-privacy informed-consent and then to exchange all QoS-information respecting security, authentication/authorization mechanisms. In the B2C case, all this is the responsibility of QoSIS.net.

QoSIS.net-based Method's Future

There are many possible scenarios, in which QoSIS.net as a part of the proposed novel business method for a MoSP QoS-assurance can evolve. For example, regarding the cost-revenue model, QoSIS.net can provide QoS-monitoring and QoS-predictions services as separate services, and reward a user of QoS-monitoring service (i.e. producing QoS-information) while charging a user for using QoS-predictions service (i.e. consuming QoS-information). This however brings to QoSIS.net a risk of not having enough contributing users in B2C case; statistics for Web 2.0 indicate that at the launch of any service, only 1% of users is willing to contribute and generate the content (Arthur, 2006).

The other possible future scenario in the B2C settings is related to the situation where a user would like to use QoSIS.net, however, he is not a frequent MoSP's service user (e.g. like Eric who is using his Facebook.com daily) and hence will not generate lots of 'real' mobile traffic. This kind of mobile user can be offered to use a QoSIS.net QoS-monitoring service as his mobile phone 'screen-saver'. Namely, when he would not use his mobile for a while, the QoS-monitoring service would take a role of an active mobile service user, using some WNP/wireless technology and imitating e.g. busty web-browsing, thus acquiring QoS-monitoring information at a given location-time. In such a way, QoSIS.net would acquire QoS-information enriching its databases and such a mobile user could be paid for information generation. However, the critical issue would be related to mobile device resources usage for this QoS-monitoring service (battery, capacity, storage etc.).

A scalable solution for QoSIS.net would be to limit its scope of operation to a particular city, region or country, limiting the scope of WNPs/wireless technologies for which QoS-predictions can be provided. Scoping can be dictated by the need of limiting the QoS-information to be processed by the QoS-prediction engine, or the need for higher accuracy of QoS-predictions provided for a restricted location-area. Furthermore, QoSIS.net can be limited in terms of WNPs/wireless technologies for which it acquires QoS-information. In the case of different QoSIS.net's location-based instances, they can form (short-term or a long-term) "smart-business-networks" for the purpose of delivering better services to their users roaming in locations areas belonging to different instances of QoSIS.net. All QoSIS.net instances collaborating in the business network could benefit from a larger QoS-information base for their QoS-predictions service.

Moreover, in order to enhance the QoS-information base and improve the QoS-predictions accuracy, we envision that QoSIS.net customers—MoSPs/WNPs whose users are likely to be in overlapping location-areas, can have a business relationship in which they agree to collaboratively share their QoS-information bases. All collaborating MoSPs could benefit from larger QoS-information base for QoS-predictions.

CONCLUSION

Mobile and ubiquitous service providers (MoSPs) emerge, struggling to provide to their users a QoE that is at least comparable to one the user is familiar with from the Internet. To bridge the gap regarding the lack of information about QoS-provided by different wireless network providers (WNPs) over diverse wireless technologies in a mobile users' location-time, in this chapter we have proposed methods enabling firstly a creation of an enterprise (QoSIS.net) providing such an information to MoSPs, and, secondly, usage of this information by an MoSP in its QoS-assurance business process. We emphasize that the aim of the proposed methods is to facilitate fulfillment of MoSP's user's QoS-requirements and his expected-QoE, hence securing the revenues of a MoSP, while creating revenues to QoSIS.net.

Future research opportunities within the domain of our topic relate to further advancements of the proposed methods for QoSIS.net and its customers, e.g. understanding the dependencies between the QoS-provided by a WNP/wireless technology and the MoSP user's QoS-requirements and his QoE-expectations, and this for MoSPs in different application domains. Related to this, a second research opportunity can focus on the efficient market entry approach for QoSIS.net as enterprise, such that it overcomes initial hurdle of attracting the required critical mass of users and start generating revenues. A third research opportunity lies in understanding the partnership-trust required in the QoSIS.net's value chain, as well as the challenges in QoSIS.net's customer management in the B2B and B2C market segments. Finally, we indicate a need for research on trust in technology. This research investigates dependability features of architectural QoSIS-system design and technical details included in SLAs established between enterprises (QoSIS.net, WNPs/MNOs), e.g. security of QoS-information exchange between enterprises.

The future research opportunities relate particularly to research on new competitive methods that can be employed in existing management, operational (i.e. core) or supporting business processes of mobile and ubiquitous service providers as enterprises. These methods need necessarily aim in satisfying their customer, while increasing enterprise revenues. We propose these methods to be based on emerging trend of short- and long-terms business inter-dependencies (i.e. "smart-business-networks") between different enterprises, bringing into a value network different, but complementary expertise. This has a high risk of failure but also a huge potential to increase revenues of all of the involved enterprises and that by increasing a customer's QoE anywhere-anytime-anyhow.

Moreover we propose research on novel methods employing the user-collaborative information sharing paradigm, i.e. Mobile Web 2.0. The risk of these methods is mainly related to attracting a critical mass of contributing users. These methods would aim at creating new revenue streams from user-generated content-manipulation and enrichment. The enriched content could then be become a part of an enterprise service, consumed back by the users. The Mobile Web 2.0-based methods however require careful research upon the content type to be generated-consumed by the users. Therefore, answers for research questions like: what is the pre-existing offline information possessed by users, which, if available to be manipulated and shared online amongst them could empower them in some way?, Does this information violates in any way user's privacy?, And what is user's willingness to share this information online and with whom?, are critical.

We envision that in order to fulfill the dream of providing mobile services meeting users' QoE-expectations and generating revenues, MoSPs need to take a necessary risk and employ novel methods in their existing business processes.

Chapter 5.19
The Pedagogical Implications of Web 2.0

ABSTRACT

Web 2.0 tools like blogs, Wikis, and podcasts are new to the vocabulary of language acquisition. Teachers and students who take full advantage of these emerging tools will participate in more dynamic, immediate, and communicative environments that provide opportunities for meaningful experiences through social constructivist learning. This chapter aims to bring perspectives rooted in educational theory to a domain too often dominated by the technological implications of its tools and argues that social constructivism is the pedagogical paradigm for learning and teaching facilitated by the next generation of Web technology. It reviews basic theoretical tenets and discusses their implications. Social constructivism lays the foundation for learning environments that foster the participation of students and teachers in today's knowledge and information-based society to their full potential.

INTRODUCTION

Language learning in the 21st century has new tools at hand. Tools like blogs, wikis, and podcasts are new to the vocabulary of language acquisition. Language learning environments are evolving into more dynamic, immediate, and communicative environments. The traffic on second language Web sites like *BBC Learning English* demonstrates the growing popularity and reach of online language learning. Concurrent with the development of the Internet over the past 20 years, learning has become intertwined with learning online; more and more people are looking for flexibility and independence in their language learning experiences.

The emergence of new technologies has always been accompanied by promises of the transformation of learning and teaching. In *Teacher and Machines*, Cuban (1996, p. 3) states that “educators [have] searched for means of communicating knowledge in simple, inexpensive, and timely ways” while “making instruction both productive and enriching” (p. 3), all in the name of transforming education to serve more students more efficiently. Cuban continues to say that “because teachers believe that interpersonal relations are essential in student learning, the use of technologies that displace, interrupt, or minimize that relationship is viewed in a negative light” (1996, p. 61). Although Cuban has argued that technologies have been oversold, he also makes a case for computers being underused in modern education. Apart from the promise of “more efficient and productive” educational institutions, the “transformation of teaching and learning into an engaging and active process connected to real life,” and “the preparation of the current generation of young people for the future workplace” have been major goals of educational technology reform (Cuban, 2002, pp. 13-15).

The promise of Web 2.0 technologies is different. Their impact on the learning process and the practice of teaching is truly revolutionary in that it does not promise more efficiency but it extends the relations between teachers and students beyond the two-dimensional models of instruction to multidimensional networks that resemble the world we live in closer than ever before. However, the role of technology represents a site of struggle with effects on the quality of learning opportunities. As Warschauer (2006) argues, “Educational reformers suggest that the advent of new technologies will radically transform what people learn, how they learn, and where they learn, yet studies of diverse learners’ use of new media cast doubt on the speed and extent of change” (p. 1).

BACKGROUND

Many educators consider correspondence education the precursor of distance education. Correspondence education developed in the mid-19th century and this was the only way to reach students who were physically separated from their instructor. By the mid-20th century, education models had evolved to computer systems built to also increase the efficiency of instruction by delivering learning packages to a large number of students, for example via PLATO (Programmed Logic for Automatic Teaching Operations) (Berners-Lee & Caillau, 2000, p. 85). In the late 1960s, a computer-assisted instructional system called TICCET (Time-shared, Interactive, Computer-Controlled Educational Television) was developed by combining computer with television technology to deliver large amounts of individually controlled instructional material to students. It was not until the 1980s that progress in the areas of speech recognition, machine-assisted translation, Artificial Intelligence and generally Natural Language Processing was made to a significant extent. While computers became more available to the average consumer and the World Wide Web was invented they didn’t enter the public sphere until the early 1990s. From this the first generation of the Web as an environment for learning emerged, giving teachers the tools to create and disseminate electronic and digitized learning materials in more efficient ways much like correspondence courses once did with print-based resources. The learning paradigm as such remained unchanged.

Many influences have had an impact on the world of learning and on shaping the online learning landscape of the second generation of the World Wide Web, the Web 2.0 era. Richardson’s (2006) book, *Blogs, Wikis, Podcasts, and other Powerful Web Tools for Classrooms* has been recognized for the use of blogs in the classroom as a “trendsetter in education” by the *New York Times*. The underlying concepts of the use of Web tools in this book are spreading throughout the online education community. Richardson states that "every educator needs to understand the potential impact of these tools [and the implications of] the social connections that students are now making on the Web, the ability to share and contribute ideas and work, the new expectation of collaboration, and the ability to truly extend the walls of our classrooms" (2006, p. viii). Throughout the book, Richardson describes these free and easy to use Web-based services to create blogs, wikis, RSS feeds, podcasts, and social bookmarks as learning tools for a constructivist and collaborative pedagogy with considerable relevance to curriculum standards.

A hugely popular blog created by the Public Library of Charlotte & Mecklenburg County called *Learning 2.0* lists *23 Things* or small exercises developed for their staff to explore and expand their knowledge of the social Web. The blog was developed to provide professional development on Web 2.0 tools using Web 2.0 tools and has been copied, commented on, contributed to by many people, much in the same way that Richardson describes the potential of these tools for education.

While there is still some disagreement about just what Web 2.0 means, O'Reilly, a supporter of the Open Source Movement and credited with coining the term Web 2.0, states that "Web 2.0 is the network as platform, spanning all connected devices … creating network effects through an 'architecture of participation,' and going beyond the page metaphor of Web 1.0 to deliver rich user experiences" (O'Reilly, 2005, n.p.). Downes, a senior researcher at Canada's National Research Council, who has been regularly writing about Web 2.0 and its impact on education for some time, echoes O'Reilly's definition of Web 2.0 but underlines that most importantly, Web 2.0 is "a social phenomenon embracing an approach to generating and distributing Web content itself, characterized by open communication, decentralization of authority, freedom to share and re-use, and the market as a conversation" (Wikipedia, 2007, n.p.).

Web 2.0 tools have now become so widely available that many students are already using them (Prensky, 2001, 2004). What's more, students are using these tools in substantially different ways than any learning tools before: "The possibilities of what *Digital Natives* can do online are growing exponentially" in ways that "online life has become an entire strategy for how to live, survive and thrive" and "it's as though the cognitive structure were parallel and no longer sequential" (Richardson, 2006, pp. 6-7). Godwin-Jones (2007), a frequent contributor to *Language Learning and Technology* states that "the much-ballyhooed Web 2.0 is essentially a transition from online consumer to consumer/producer/participant" (p. 8), a self-construct that many students embody quite naturally.

Web 2.0 as an emerging social technology phenomenon is at the heart of what we have come to understand as e-Learning 2.0, environments encouraging collaborative learning via the use of innovative, community driven technologies and tools. Because of the Open Source Movement, a set of principles and practices that promotes access to the development of design and the production of software, user-generated content can now be created through individual effort or through collaboration among instructional designers.

MAIN FOCUS OF THE CHAPTER

With the arrival of technologies that provide a variety of media connecting students to teachers, peers and learning materials, online learning has come to describe a new way of reaching students and connecting them with one another. Today's instructional models have to address the complexities of online learning environments, meeting the needs of students and teachers to learn and teach in an effective way as well as the demands online learning places on them to rediscover and redefine learning and teaching practices.

Online learning students and teachers have different motivations; they may prefer working independently from their peers or they may face barriers of transportation, scheduling, and/or accessibility to services that prevent participation in a traditional school. More and more students and teachers, however, make a conscious choice to learn and teach online, with new technology in mind that makes new ways of learning and teaching possible. For instance, in the case of immigrants who are awaiting passage to new countries, online learning provides an excellent opportunity to develop the language skills and acquire cultural knowledge they will need in their new country. Today, education brings together life-long learning theory with the ideas of distributed, blended, and flexible learning that have emerged within the context of technology-based instruction over the last two decades

As new computer and communications technology has emerged, together with software applications such as browsers and other clients, distance learning has become synonymous with learning online. However, while distance learning carries the interpretative baggage of its principal defining characteristic, that is the physical separation between student and instructor, online learning is often too narrowly defined by the extent of networks such as the Internet or intranets. While both promise learners to be able to learn anytime and anyplace to a lesser or greater degree, the implications for how students learn and teachers teach run deeper. Overall, it can be stated that online learning uses technology to breach the distance where there is a separation of student and instructor in time and space.

In exploring the potential use of technologies as a medium for learning, authors and academics have looked at the challenges for students and teachers. These challenges have defined our understanding of Web-based learning and teaching and guided us closer and closer to the paradigm shift exemplified by Web 2.0 environments, but a common understanding about aspects of quality and the different perspectives available in the design of online and distance learning environments is still needed.

The following statements may best reflect common convictions about learning that online learning environments should bring to life from the perspectives of developing a program primarily based on the technological infrastructure, the availability of learning content, and providing flexibility to learners:

- **Technology perspective:** Learning is *distributed* in that it "makes use of mixed or multimedia tools to bridge the distance between teacher and learner" (Utah Education Network, 2007, n.p.).
- **Content perspective:** Learning is *blended* in that it "employs multiple strategies, methods, and delivery systems" including e-based and print-based resources (Node, 2001, p. 5).
- **Learner perspective:** Learning is *flexible* in that it "expands the choice on what, when, where, and how people learn" (Australian National Training Authority, 2003, p. 3).

Over the past 20 years, at the same time as education has become intertwined with learning online, the Internet has evolved from information and communication technology environments to a network of virtual spaces built on the dynamics of social communities. This second generation of the World Wide Web has come to be known as Web 2.0 bringing social aspects to the foreground while technology steps into the background and fulfills its intended purpose as a medium for learning and teaching.

The emphasis on community and social networks in Web 2.0 has a strong connection to theories of social constructivism and the learners' need to create meaning. Within this context social-constructivist learning theory has reemerged as an approach to learning independently and embedded within a social community. Social constructivism is the approach for online and distance learning for the e-Learning 2.0 paradigm and the Web 2.0 era.

As the tools of e-Learning 2.0 make their way into the hands of users, creating community and working with others online has become easier. Language learning blogs are being used to connect ideas and people around the world, educational podcasts and the communities that pop up to develop and listen to them are a vibrant and valuable phenomenon, *YouTube* has found its way into everyday language. Ideas about the decentralization of authority, freedom to share and re-use information fit perfectly with modern notions of learning as less of a transfer of knowledge from a teacher and more of students learning from each other. *WikiEducator* has begun a listing of free classroom handouts and is planning to encourage teachers to collaborate on developing free textbooks using the wiki platform.

A New Way of Learning and Teaching

Face-to-face instruction often assumes the teacher's ownership of knowledge and transmission of it to the learner, while online learning should be built with the student at the centre of the learning environment. A social-constructivist approach helps focus resources and support for learners to enable them to actively use new material rather than passively absorb information presented to them. According to Warschauer (Berners-Lee & Caillau, 2000, p. 93), the evolution of Computer-Assisted Language Learning can be divided into 3 trends: Behavioral, Integrative, and Communicative, mirroring the evolution of technology and the evolution of linguistic and instructional sciences. The shift to a social-constructivist approach signifies a fundamental change to "willful, reflective, active, conscientious and constructive" learning (Jonassen & Land, 2000, p. v) and collaborative learning represents a key concept between teachers and students within this approach.

Berners-Lee and Caillau (2000) state that:

"in the past, methods have tended to be specialized and exclusive in technique, banishing what preceded to the scrapheap of failed technology [but] it is now generally believed that successful language learning involves competence in a large number of complex and integrated skills and that successful language teaching is more likely to result from using a combination of several different language teaching approaches as no single approach can be said to be entirely successful on its own." (p. 101)

As the epistemological foundations on which social-constructivist convictions are built, differing from cognitive theories of learning (Jonassen & Land, 2000) by expanding on them, there is much room to accommodate different teaching approaches. Social constructivism presumes that learning is a process of individual interpretation and meaning making based on a variety of experiences, and that knowledge is constructed from these experiences (Jonassen, 1991). Additionally, social-constructivist learning processes state that social interaction or social constructivism is not merely supportive of but an essential ingredient in cognitive development (Duffy & Cunningham, 1996). These fundamental changes envision learning as a social dialectic process of meaning. A learning event is characterized by internal and social negotiation between participants of an activity situated in a community. This represents a paradigm shift in the way we think of the process of learning, and the learning medium. The locus of knowledge shifts from the teacher to the learner.

This approach values authentic activities that allow learners to explore, discuss, and construct concepts and relationships relating to real-world problems and projects. Content must be relevant and meaningful to the learner (Donovan et al, 1999). This type of learning is situated in communities of learning and practice as opposed to within the minds of individuals (Lave & Wenger, 1991). Collaborative learning is a key concept between instructors and students, and "two-way interaction is critical in learning a second language" (Ariza & Hancock, 2003, p. 2). The interactions between student-teacher, student-student and student-content are the main media for learning to take place, and specifically for language learning the two-way interaction is important (Pica, 1996). Ariza and Hancock (2003) explain that "while Krashen (1994) believes that only one-way comprehensible input is required for Second Language Acquisition" (pp. 2-3), Lightbrown and Spada (1999) believe that students learn best "when [they] are given the opportunity to engage in meaningful activities [and] are compelled to negotiate for meaning, that is, to express and clarify their intentions, thoughts, opinions, etc., in a way which permits them to arrive at a mutual understanding. This is especially true when the learners are working together to accomplish a particular goal" (p. 22). The possibility and desire to include two-way interactions represent one of the important developments over the history of using technology in language learning and in the history of approaches to language learning in general.

Especially for second language learning, the immersion of learners in authentic environments is paramount. Authentic environments are those that make learning meaningful to students, often because they have a common goal either to achieve a similar outcome or to engage in a similar learning process. Authentic environments need to be situated in real world contexts that learners can relate to because of their previous life, education, or work experiences. As an alternative or even at the same time, authentic environments can be situated learning environments that create contexts similar to the real world in which learners will have to apply the skills that they are learning. The terms "authentic" and "situated" learning are often used interchangeably.

This experience of immersion into a new learning environment and the adaptation to a new way of learning is a profoundly social-constructivist experience where learning through knowledge acquisition and problem solving can take place. In order to arrive at a successful skill transfer to and application of knowledge in another concrete context, learning must occur in authentic environments and be based on the learning of general skills that are transferable to a variety of situations (Winn, 1993).

In authentic learning environments such as these, knowledge and skills are acquired through a process of social communication and discourse. Activities that focus on social communication and discourse also focus on the connections with the community and the patterns of participation, that is connections with the community comprised of all participants who contribute to the learning experience and in the ways they contribute (Duffy & Cunningham, 1996).The following basic tenets may be derived for the practice of pedagogical design:

- Learning is a process of construction based on and situated in experience.
- Learning is based on the instruction of authentic and transferable skills.
- The student is at the centre of the learning process.
- The student is a distributed and multidimensional participant.

e-Learning 2.0

The term e-Learning 2.0 appeared first in an online article by Downes in 2005, referring to a second phase of e-learning embedded in Web 2.0 environments. It describes a new generation of e-based learning environments that allow students to create content, collaborate with peers to form a learning network with distribution of content creation and responsibilities.

According to Karrer in *Understanding e-Learning 2.0*, the second generation of the Web is one of the primary forces behind this new learning paradigm. The key components to Web 2.0 are its tools that allow for collaboration and social interaction to take place. Karrer points to the emergence of a collective intelligence as a result from e-Learning 2.0 that unfolds naturally. Web 2.0 allows learning content to be aggregated together from various sources using various tools but the central idea of e-Learning 2.0 runs deeper. In many respects, collaboration and social interaction result in the creation of content rather than building collaborative learning activities around existing material.

As a result, e-Learning 2.0 also reverses the notion of traditional learning models in terms of the roles of its participants. That is, learning content is no longer produced by publishers and organized into structured courses by teachers. Students take an active part in all aspects of their learning experience, including content creation and learning management on an ongoing basis.

Teachers Learn to Teach

Within a social-constructivist learning approach teachers are generally regarded as facilitators guiding learners through their interaction with the learning material and supporting the collaboration with other learners. The teacher has the expertise and the skills to bring the student to the appropriate learning and will work to create a learning environment where knowledge building is fostered through social exchange.

On the one hand, online teachers share these characteristics with classroom teachers, and like them, must have sufficient knowledge of their subject domain and can be expected to convey enthusiasm for the subject and for their task as a learning motivator; and both types of teachers must have access to appropriate learning activities.

On the other hand, an online learning environment requires different approaches and methods. And different qualities define an online teacher. Most importantly, online teachers must also have sufficient technical skills to navigate and contribute effectively within the online learning context, access necessary hardware, and sufficient Internet efficacy to function within the inevitable technical challenges of these new environments (Anderson & Elloumi, 2004).

Special challenges confront teachers at a distance: these are also believed to hold for online learning environments in general. For example, the teacher must (Gottschalk, 1995, p. 2):

- Develop an understanding of the characteristics and needs of online students with little first-hand experience and limited, if any, face-to-face contact.
- Adapt teaching styles taking into consideration the needs and expectations of multiple often diverse, audiences.
- Develop a working understanding of delivery technology, while remaining focused on their teaching role.
- Function effectively as a skilled facilitator as well as content provider and manager.

As Gottschalk further suggests, “The instructor often finds it beneficial to rely on a site facilitator to act as a bridge between the students and the instructor. To be effective, a facilitator must understand the students being served and the instructor’s expectations” (Gottschalk, 1995, p. 2).

Teachers have an important place in these programs. Current research on distance and online learning indicates that interaction between learners and teachers through face-to-face, telephone, or electronic means is vital to the learning process in these programs (Porter & Sturm, 2006). During the course of this research, the following skills teachers need to know when working online with students emerged:

- How to use assessment tools with learners at a distance
- How to use synchronous and asynchronous online tools
- How to give appropriate feedback online
- How to motivate and encourage students at a distance
- How to create a positive learning environment online
- How to manage discussions in chat rooms
- How to organize and monitor project work online
- How to retain students online
- How to integrate technology into language learning programs
- How to facilitate learning in a Web-based environment
- How and where to grow and update their skills as new online communications and student support technologies evolve

Are teachers prepared to integrate Web 2.0 tools into their programs? The specific needs of teachers in online language learning programs are rarely mentioned. The management of online learning environments encompasses everything from administration to lesson planning to assessment and evaluation, with teachers often involved in these processes every step of the way. Warschauer (2000) noted that he sees distance education as a realm in which the role of technology will be a site of struggle in increasing or lowering the quality of learning opportunities, which could also bring to a head issues about the professional standing of educators in the field of online learning (White, 2003). Although it is often helpful and practical for teachers to develop their tech skills informally, many of these skill areas are not easy to develop without guidance.

Furthermore, teachers face additional challenges in the shape of structural and attitudinal barriers. Common structural barriers may be due to the way the computers are used within a program, if they are integrated in a way that maximizes the use of the resources available to teachers, if opportunities to practice new technology skills are available, and if the educational institution values this learning process. Common attitudinal barriers are often rooted in the way technology forces change that disrupts programs. In the early stages of technology integration, teachers are often overwhelmed and need to be motivated to continue their learning process that will result in achieving their goals of improving student independence (Kennell, 2004).

An excellent resource when considering online teacher competencies is Salmon's *E-Moderator Online Competencies*.Table 1, adapted from Salmon (2002, p. 41), presents a summary of the qualities and characteristics that Salmon states are key competencies for the changing role of a teacher in an online learning environment. She also makes the point that good face-to-face teachers do not necessarily make the best online teachers and notes that face-to-face subject teachers who are used to being "experts" might have difficulty adapting to the levelling effect and informality of online discussion (Salmon, 2002, p. 42).

The Milken Exchange's Professional Competency Continuum: Professional Skills for the Digital Age Classroom provides an interesting assessment for instructors to see where their technology skills lie on a continuum that looks at five target areas of skill: core technology skills; curriculum, learning, and assessment; professional practice; classroom and instructional management; and administrative competencies (Milken Family Foundation, 2008).

Learners Teach to Learn

Online learning skills are necessary in the wider world beyond language training. Increasing opportunities for online learning increases the learner's ability to participate in a multitude of learning opportunities and to take a leadership role among their peers. The world of work integrates online collaboration into more and more of the structure

Table 1. Key competencies of an online teacher

Quality/ Characteristic	**1. CONFIDENT**	**2. CONSTRUCTIVE**	**3. DEVELOPMENTAL**	**4. FACILITATING**	**5. KNOWLEDGE SHARING**	**6. CREATIVE**
Understanding of online process	Personal experience as an online learner, flexibility in approaches to teaching & learning. Empathy with the challenges of becoming an online learner	Able to build online trust & purpose for others, Understand the potential of online learning & groups	Ability to develop & enable others, act as catalyst, foster discussion, summarize, restate, challenge, monitor understanding & misunderstanding, take feedback	Know when to control groups, when to let go, how to bring in non-participants, know how to pace discussion & use time on line, understand the 5-stage scaffolding process & how to use it	Able to explore ideas, develop arguments, promote valuable threads, close off unproductive threads, choose when to archive	Able to use a range of approaches from structured activities (e-tivities) to free wheeling discussions, & to evaluate & judge success of these
Technical skills	Operational understanding of software in use reasonable keyboard skills; able to read fairly comfortably on screen, good, regular, mobile access to the Internet	Able to appreciate the basic structures of bullet boards, forums, & the WWW & Internet's potential for learning	Know how to use special features of software for e-moderators, e.g. controlling, weaving, archiving, Know how to "scale up" without consuming inordinate amounts of personal time, by using the software productively	Able to use special features of software to explore learner's use e.g. message history	Able to create links between online & other features of learning programs	Able to use software facilities to create & manipulate conferences & to generate an online learning environment, able to use alternative software & platforms
Online communication skills	Courteous & respectful in online (written) communication, able to pace & use time appropriately	Able to write concise, energizing, personable online messages	Able to engage with people online (not the machine or the software), respond to messages appropriately, be appropriately "visible" online, elicit & manage students' expectations	Able to interact through e-mail & conferencing & achieve interaction between others, be a role model Able to gradually increase the number of learners dealt with successfully online, without huge amounts of extra personal time	Able to value diversity with cultural sensitivity, explore differences & meanings	Able to communicate comfortably without visual cues, able to diagnose & solve problems & opportunities online, use humour online, use & work with emotion online, handle conflict constructively
Content expertise	Knowledge & experience to share, willingness to add own contributions	Able to encourage sound contributions from others, know of useful online resources for their topic	Able to trigger debates by posing intriguing questions	Carry authority by awarding marks fairly to students for their participation & contributions	Know about valuable resources (e.g. on the WWW) & refer participants to them, and use them as sparks for participation	Able to enliven conferences through use of multi media & electronic resources, able to give creative feedback & build on participants' ideas
Personal Characteristics	Determination & motivation to become as an e-moderator	Able to establish an online identity as e-moderator	Able to adapt to new teaching contexts, methods, audiences & roles	Show sensitivity to online relationships & communication	Show a positive attitude, commitment & enthusiasm for online learning	Know how to create & sustain a useful, relevant online learning community

of professional and personal life, much like many public and academic libraries have done adopting the *23 things* learning paradigm. This could be the kind of on the job training that language students might also encounter, especially internationally trained professionals and trades people.

Online learning built on e-Learning 2.0 principles, that is learning environments that employ social-constructivist principles and include Web-based environments for communal spaces of learning and teaching, make special demands on students and teachers. Students will be working with little or no face-to-face support, and without encountering fellow students in physical spaces but depending on the suite of Web 2.0 tools at their disposal they may be connected to their teacher and peers more or less in *real-time*. For instance, internationally trained individuals are often expected to connect with mentors in their field by contributing to a blog or by listening to a podcast.

In synchronous environments, that is *real-time* exchange between the participants, student support can be implemented similarly to and in some ways better than in face-to-face classrooms. The immediacy of responses that face-to-face environments provide, for better or for worse depending on the cues of teachers acknowledging or discounting students' willingness to participate, is as much the key in student retention in online environments but the net of connections between students, their peers and their teacher can be cast wider. The tools at the disposal of all participants provide for more distributed participation patterns with the potential of supporting students adequately. Also, it is easier for students to seek support from their peers in a less disruptive manner to the group when using tools like chat or instant messaging concurrently with virtual classroom applications, such as *Centra* and *Elluminate*.

In asynchronous environments, when students are also separated in time from the teacher and their peers and cannot expect to get an immediate response, they must be able to maintain their motivation on their own even though feedback from teachers and fellow students may be delayed. Online learning options that merely distribute learning materials by electronic means for the sake of access, expediency, and convenience without adding the value to Web 2.0 tools to enrich students' experiences suffer the same fate as correspondence courses and remain one-dimensional and undistributed. When designed and employed at the service of students and teachers within a community, asynchronous tools cannot only give anytime anywhere access to learning but can also empower students to self-manage their learning experiences, and take on roles of expertise and leadership among their peers at their own pace.

Often an ideal learning environment is built around both synchronous and asynchronous elements that provide students and teachers with an array of communication and learning tools. In order to be most effective in any online program, students need to be willing to work towards becoming more autonomous and self-directed to fulfill their multi-dimensional and distributed connections with other participants in the same space. This is substantially different from traditional classrooms where one-to-one and group-to-one interactions are mandated by the limitations of a physical environment. In order to participate to the fullest and be successful, students must see that they have an essential part to play to bring the benefits of online learning environments about. According to the Illinois Online Network (2007, n.p.), students need to:

- Be open minded about sharing life, work, and educational experiences as part of the learning process
- Be self-motivated and self-disciplined
- Be willing to "speak-up" when problems arise
- Be willing and able to meet the minimum requirements of the program
- Accept critical thinking and decision making as part of the learning process

- Be able to think ideas through before responding
- Feel that high quality learning can take place without going to a classroom

Naturally, some students begin with more skills for online learning than others. Students without online learning experience may perform lower overall than students with online learning experience. Inexperienced students may communicate more about difficulty with software, the course management system, or mistakes in submitting work online. In contrast, experienced students may perform better overall and their more frequent communications may be indicative of seeking clarification of course concepts at higher levels. At any stage, students need to engage in self-assessment as a key step in the process of learning online successfully. Furthermore, "multi-modal, multi-tiered products … provide students a vehicle for drawing on varied strengths and making positive contributions, regardless of whether they are fluent in [a second language]" (Warschauer, 2007, p. 2536).

Some studies have shown that "women may be more successful in online environments than men because they frequently create a sense of community by connecting with other learners" (Imel & Jacobson, 2006, p. 2; Rovai, 2003). In a learning environment that relies on students to communicate not just with a teacher but with other students as well, this is important to keep in mind for teachers customizing an e-Learning 2.0 environment. Furthermore, younger adults are more likely to drop out of online classes than older classmates (Jonassen et al., 1999) because they may not have the same learning persistence. On the other hand, many younger students are more adept at using a computer and are more familiar with e-mail, chat rooms and the Internet in general than older students. With a variety of Web 2.0 tools at hand, teachers need to select the ones that meet the needs of their students and keep up with the demands of the learning material.

The ability of learners to manage their own learning is a key competency that studies have shown to be related directly to successful participation in online learning environments. Porter and Sturm (2006, p. 105) used the following self-management survey to evaluate learners competency level by asking them about how well they thought they did in the these areas:

1. Staying focused or concentrate on what they are doing
2. Sticking with a task or problem
3. Figuring things out for themselves before asking for help
4. Asking for help when they're stuck
5. Making decisions for themselves
6. Solving problems by themselves
7. Feeling they can do things and accomplish things
8. Organizing their work and life
9. Learning things on their own
10. Setting goals for themselves
11. Managing their time
12. Evaluating their own progress and how they are doing
13. Trying or learning new things
14. Learning on their own without help
15. Accepting responsibility for themselves
16. Seeking constructive criticism of their work
17. Trying to actively try new things

The Pedagogy of Blogs and Wikis

Years before the emergence of Web 2.0 tools, Jonassen, Peck and Wilson (1999) argued that using technology as storage places for learning material does not exploit the capabilities of technology, teachers and students, but that technology can amplify students' ability to construct knowledge. Jonassen, Carr, and Yueh (1998) described "computer applications that, when used by learners to represent what they know, necessarily engage them in critical thinking about the content they are studying" as mind tools, and continues to say that "mind tools scaffold different forms of reasoning about content. That is, they require students to think about what they know in different, meaningful ways. … Students cannot use mind tools as learning strategies without thinking deeply about what they are studying" (p. 1). Web technology should be used to engage students in critical thinking and enable them to become intelligent designers when computers and networks serve as catalysts for facilitating planning, decision-making and self-management skills when they are used in ways to promote reflection, discussion, and problem-solving by the teacher.

Blogs and wikis exemplify these possibilities in powerful ways for students and teachers. Richardson (2006) calls blogs "a truly constructivist tool for learning" (p. 27) because their content is part of a wider body of knowledge accessible and potentially relevant to an audience outside the classroom. A high degree of *information literacy* is required. The American Library Association defines *information literacy* as "the ability to access needed information effectively and efficiently; evaluate information and its sources critically; incorporate selected information into one's knowledge base; use information effectively to accomplish a specific purpose; and understand the economic, legal, and social issues surrounding the use of information" (Warschauer, 2007, p. 2512). Furthermore, blogs and wikis facilitate reflection and metacognitive analysis through archiving, they support different learning styles, and they provide students with opportunities to acquire the new literacy skills needed in a more and more knowledge and information-based society (Richardson, 2006). Writing on a blog is not merely writing using another medium; the medium transforms the writing process and extends its reach by making it more conversational, collaborative and in the end democratic.

Wikis take the democratization of learning even further by allowing everyone to be an editor and thus exemplary collaborative learning to emerge, including astounding self-regulatory practices of quality control. *Wikipedia*, the online encyclopedia build on the wiki paradigm, is the "poster child for the collaborative construction of knowledge and truth that the new, interactive Web facilitates" (Richardson, 2006, p. 61). Wikipedia has grown rapidly into one of the largest reference Web sites since 1995 and has sparked the emergence of other tools based on the wiki paradigm of collaborative knowledge management like the *WikiEducator*, an evolving community intended for the collaborative planning of education projects linked with the development of free content.

Because of the potential of open source products like wikis, many education institutions have been moving away from their exclusive use of more restrictive commercial systems, their recurring licensing and upgrading fees being only part of the problem. Many still retain these systems due to the need for the learning management features they provide, but more and more are trying out and reporting success with open source systems like *Moodle* that is designed to help educators create online courses with opportunities for rich interaction and manage groups of students effectively by providing a free online learning platform supported by a global community of developers. *Moodle* is designed to be extremely flexible for instructors and learners, and can be downloaded and used on nearly any mainstream computer; it readily scales from single-instructor or departmental Web sites to 50,000-student universities (Instructional Technology Resource Center, 2006).

Although quality control in Web 2.0 learning environments is a major challenge, for instance Richardson (2006) adds that because of the wiki's democratic process of knowledge creation students begin to teach each other when put to the task to negotiate to agree on correctness, meaning, and relevance with their peers. With a system as openly accessible as *Wikipedia*, its potential for collaborative learning appears to be matched by its potential for unethical use. When anyone can make changes, information can be easily falsified, and the collaborative community serves as a watchdog. Richardson argues that "giving students editorial control can imbue in them a sense of responsibility and ownership" (p. 64).

Many Web 2.0 tools come together seamlessly within blogs, wikis, and learning management systems like *Moodle*, such as automatically updated RSS (Rich Site Summary) feeds from news Web sites and other blogs, audio and video podcasts (vodcasts) from amateur and professional producers, or social bookmarking features, to name just a few tools that extend the reach of distributed learning applications. The community building properties of blogs and wikis, along with other synchronous or asynchronous Web-based communication and content creation tools, build communities of practice into the paradigm of an online learning environment. In traditional classrooms, there are often social communities or cliques but they are rarely based on common learning goals since knowledge building is seen as rooted in the individual student's learning process.

FUTURE TRENDS

Language learning environments that traditionally provide opportunities for repetitive practice can still help students with lower language proficiency master the skills they need before they can handle Web 2.0 tools like blogs and wikis effectively, but it is also important to keep in mind that students' language proficiency does not necessarily parallel their familiarity and proficiency with technology. Many students may have had varied experience with Web 2.0 tools using them for professional or personal reasons. Given the growing extent that these tools are integrated in today's working environments, communal and personal spaces, the more they are integrated in learning environments the more authentic learning experiences are and the higher rate of skills transfer students experience.

It has become more and more likely for students to be asked to create and manage content for Web 2.0 environments. Richardson (2006) points out that there is a clear disconnect between the traditional teacher who grades independent study assignments aimed at a very limited audience and the students who need to be critical readers of Web-based content, literate in Web 2.0 publishing, comfortable with virtual collaboration, and good information managers. It is this disconnect that may present a major barrier in student achievement.

According to Warschauer (2006), "the ability to learn autonomously will indeed be critical in the digital future" and he continues to say that "strong mentorship is required for students to achieve this autonomy" (p. 46) at the same time. It is through the multi-dimensional ways that Web 2.0 learning environments allow learners to connect and collaborate with teachers and other learners that independent learning and meaning making embedded in a social context and constructs is made possible. Richardson (2006) identifies the social, collaborative construction of meaningful knowledge as one of the paradigm shifts that Web 2.0 technologies demand a reexamination of the way we learn and teach. Producing work in truly collaborative ways for large audiences creates a new social context that requires teachers to rethink the demands placed on the students. Instead of completion of an assignment, contribution to project becomes more and more the ultimate goal. As Warschauer (2006) comments, "New technologies do not replace the need for strong human mentorship, but, indeed, amplify the role of such mentorship" (p. 48). Teachers need to see themselves as *connectors* not only between students and the learning content but also with their peers. They also need to become *content creators* using Web 2.0 tools, *collaborators* in the sense of learning alongside their students, and *coaches* modeling skills students need as well as motivating them to take responsibility and ownership for their own performance. Last but not least, teachers need to become *change agents* using Web 2.0 tools to move towards a new way of learning and teaching (Richardson, 2006, pp. 132-133).

CONCLUSION

In this chapter, social constructivism has been proposed as the foundation for online language learning environments that foster the participation of students and teachers in today's knowledge and information-based society to their full potential through the use of Web 2.0 tools like blogs and wikis. It has been argued that teachers and students need to take full advantage of these emerging tools to participate in more dynamic, immediate, and communicative environments that provide opportunities for meaningful experiences through social constructivist learning.

While putting the pedagogy of blogs and wikis to work may take some time, the following recommendations can assist program designers and teachers in making the first step towards participatory and collaborative online learning of the Web 2.0 era:

- Where possible, orientation "events" should be held to introduce students to the requirements of the technology and the expectations for student-to-instructor and peer-to-peer communication. The orientation process can be a critical factor in the success of online learning programs (Johnston et al., n.d.).
- When possible, begin the course by providing traditional face-to-face instruction and then blend it with online education. Face-to-face instruction can provide students with a little online learning experience with support and help them develop confidence in their ability to succeed using on-line learning tools (Johnston et al., n.d.).
- Help students develop their ability to engage in self-directed learning. If the online learning program is complemented with some traditional instruction, teachers can spend time in class working with students on self-management strategies and help change their perceptions of themselves as students and allowed them to take ownership of their learning (D'Amico & Capehart, 2001). Provide opportunities for students to take leadership and engage in peer tutoring.
- In an online learning program, ongoing support should be provided for students through frequent contact with teachers via multiple modalities, e.g. e-mail, instant messenging, chat, or telephone contact. Learners should be offered opportunities to participate in online learning at the earliest possible point in their language learning.
- A tool for students to self-assess their online learning skills should be accessible to them. This tool should assess students' familiarity with technology, their experience in online learning, their problem solving skills, their ability to motivate themselves, their level of self-directedness as well as their level of English fluency. The results should be shared with the student to help in determining their preference for learning environments.
- Encourage students and fellow teachers to explore and experiment with Web 2.0 tools and their potential for learning and teaching. Professional development activities should take advantage of the same technologies so that teachers learn about e-Learning 2.0 the same way students would and understand the implications of the demands placed on students and their expectations better.

KEY TERMS

Blended Learning: The term Blended Learning describes the design of a learning environment from the viewpoint of how the delivery of learning materials to the students is best accomplished by a variety of means available, be they technological or non-technological in nature. By choosing the appropriate vehicle for the student to access the learning content, a number of different strategies are used to provide hybrid learning environments. Blended Learning is closely related to Distributed Learning and Flexible Learning.

Distributed Learning: This term refers to learning environments that use a mixture of tools to navigate the distance between teachers and learners. From a design viewpoint of a learning environment, building a variety of connections between the participants and the learning content is the main objective, as is allowing patterns of participation to develop between teachers, students and learning materials. Technological tools allow these connections to be made easily. Distributed Learning is closely related to Blended Learning and Flexible Learning.

e-Learning 2.0: The term e-Learning 2.0 refers to the second generation of eLearning making use of the social collaboration and information sharing tools embedded in Web 2.0 environments. It describes a new generation of e-based learning environments that allow students to create content, and collaborate with peers on the creation of content distributed by technological tools. e-Learning

2.0 provides a new learning paradigm naturally unfolding collective intelligences.

Flexible Learning: This term describes a learning design perspective deeply rooted in the needs of students, with the main objective being to provide them with the most flexibility about the learning content, schedules, access, and learning styles as possible. A flexible learning design customizes learning environments to meet the needs of learners, using both technological and non-technological tools. Flexible Learning is closely related to Blended Learning and Distributed Learning.

PLATO: Programmed Logic for Automated Teaching Operation, refers to one of the first computer assisted instruction systems, dating from the early 1970s and running until 2006. PLATO was one of the first systems to test applications such as e-mail, discussion forums, and chat rooms.

TICCET: This stands for Time-shared, Interactive, Computer-Controlled Educational Television. The project ran at the same time as PLATO and was funded by the University of Texas at Austin and Brigham Young University. In place of expensive hardware, the system used television technology with minicomputers to deliver interactive educational content.

Wiki: This is a Web-based environment designed to enable readers to become creators of content and editors of previous entries. Wikis are paradigm examples of Web 2.0 tools that are effectively used to design constructivist learning environments and engage learners in collaborative learning environments. Much like blogs, wikis integrate different types of media from audio to video files, which can be played on demand, as well as podcasts to vodcasts, which readers can subscribe to. Wikis can be an integrated part of a larger learning management system.

This work was previously published in Handbook of Research on Web 2.0 and Second Language Learning, edited by J. Wang, pp. 367-384, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 5.20
Developing Digital Literacy Skills with WebQuests and Web Inquiry Projects

Susan E. Gibson
University of Alberta, Canada

ABSTRACT

This article identifies digital literacy as an important aspect of new media literacy at the K-12 level. Digital literacy includes developing the skills of information location and application as well understanding how to use available evidence to assist in problem solving and decision making about important questions and issues that have no clear answers. Two web-based examples of instructional strategies – WebQuests and Web Inquiry Projects—are suggested as ways to develop these and other important 21st century learning skills.

WHAT IS DIGITAL LITERACY?

Over the last decade the term ' literacy' has evolved to include an ever increasing, and diverse range of skills. "The new literacies of the Internet and other ICTs include the skills, strategies and dispositions necessary to successfully use and adapt to the rapidly changing information and communication technologies and contexts that continuously emerge in our world and influence all areas of our personal and professional lives" (Leu, Kinzer, Coiro & Cammack, 2004, p. 1572). According to Jamie McKenzie (2005), "Literacy is about wrestling understanding from chunks of information, whether these chunks be numerical, textual, visual, cultural, natural or artistic" (p. 7). One form of literacy, 'digital' literacy, can be defined as "a person's ability to perform tasks effectively in a digital environment, with "digital" meaning information represented in numeric form and primarily for use by a computer... [and] includes the ability to read and interpret media (text, sound, images), to reproduce data and images through digital manipulation, and to evaluate and apply new knowledge gained from digital environments" (Jones-Kavalier & Flannigan, 2006, p. 9).

Developing the skills of information location and application is one aspect of **digital literacy**. These skills include the ability to find, evaluate, synthesize, and use information to answer questions and make informed decisions. Digitized information comes in many forms, and students need to acquire the ability to read, interpret, understand, and use all of these media formats. They need to understand that

DOI: 10.4018/978-1-60566-120-9.ch026

everything on the Web represents an individual's point of view and that all sources need to be carefully and critically examined for authenticity and bias. They also need to recognize that no one source of information can adequately represent all there is to know about a particular topic; multiple sources on any topic should always be consulted and their information compared. **Digital literacy** also involves understanding how to use the available evidence to assist in problem solving and decision making about important questions and issues that have no clear answers. Furthermore students benefit from opportunities in which they are encourage to transform information in new ways to advance their own and other's thinking, rather than simply consuming what others have produced. Finally, students need to develop a critical attitude toward computer technology in our society in terms of its present and future impact on humanity. The overall goal of **digital literacy** is to develop knowledgeable, skilled, and responsible users of computer technologies.

The Partnership for 21st Century Learning [http://www.21stcenturyskills.org/index.php?option=com_content&task=view&id=254&Itemid=120] calls for an emphasis in schooling on all of these literacy skills to ensure that students will be successful in the 21st century. The International Society for Technology in Education's (ISTE) Standards for Educational Technology (2007) also include creativity and innovation, communication and **collaboration**, research and information literacy, critical thinking, problem solving and decision making, digital citizenship, and technology operations and concepts. Addressing all of these components of **digital literacy** is a major undertaking for schools and all teachers, grade levels and subject areas have important roles to play.

This chapter begins by reviewing what we currently know about effective computer use to support and enhance teaching and learning. **Constructivism** is then examined as a promising theoretical framework for that use. The remainder of the chapter looks at **WebQuests** and their extension, **Web Inquiry Projects**, as approaches that have the potential to effectively address both constructivist learning principles and digital literacy, **higher level thinking**, problem solving and communication skills.

WHAT DOES THE RESEARCH TELL US ABOUT WHAT MAKES EFFECTIVE AND MEANINGFUL TECHNOLOGY INTEGRATION?

Before examining ways to address **digital literacy** skills in teaching with technology, it is important to review what we know about effective technology use. Computers are now more readily available in many schools worldwide and the Internet is often hailed as an innovation with unprecedented potential for the improvement of teaching and learning. Although some critics claim that the use of computer technologies has had minimal to no affect on learning outcomes (Cuban, 2001, Oppenheimer, 2003), there have been positive affects identified in the research literature. "Several recent research reviews and meta-analyses published in the United States and Britain suggest that, when measured across the board, educational technology yields "small, but significant" gains in learning and student engagement" (Viadero, 2007 p. 1). Learner motivation has been identified in numerous studies as being particularly evident with the use of computer technologies (Sterling, 2007). As for learning gains, Wan, Fang, and Neufeld (2007) found that, "Technology can influence learning processes by facilitating cognitive information processing activities such as search, scanning, transformation or comparison of information" (p. 187). Higgins (2004) found advances in reasoning, understanding and creativity using computers. Viadero (2007) identified positive affects for writing with the use of word processors, and for generating deeper understanding and increasing knowledge through the use of simulations. Balanskat, Blamire and Kefala (2006) analyzed the evidence from 17 impact studies and found that using information and communication technologies had a positive impact on children's' learning of basic skills such as calculation, reading and writing, and on communication and process skills, while also allowing for greater differentiation to address individual needs and learning styles, and giving more responsibility for the learning to the student. The greatest benefits, according to Balanskat et al. (2006), were seen in primary education. Significant benefits have also been found in the areas of special needs (Hartley, 2007) and English as a Second Language (Lee, 2006).

While the benefits from the use of computer technologies are evident, K-12 teachers continue to be at varied levels of awareness about the possibilities for employing these technologies in effective and efficient ways to enhance teaching and learning. "Effectively integrating new technology into educational practice is not just a matter of learning how to use technology. It is also a process of reflecting on how to teach and how students can learn most effectively in today's world" (Wiske, Franz, & Breit, 2005, p. 3). Where the greatest challenge for teachers lies is in thinking differently about teaching and learning. According to David Thornburg, "The main thing that's holding technology back is...a fear--a well-placed fear, I might add--that if technology becomes ubiquitous, it will totally transform the practice of education. There are a lot of people who don't want the practice of education transformed because they're very comfortable with it" (cited in Brumfield, 2006, p. 1). Computer technologies can help teachers to develop new approaches to teaching and learning, but teachers need to be exposed to these new understandings and new capabilities. They also need to determine where technologies fit into their philosophy of teaching. As noted by Doolittle and Hicks (2003), "A philosophical and theoretical foundation provides answers to the questions of why and how specific pedagogy, including the application of technology, should be employed" (p. 76). The key to best use is not the fact that computers are being used, but how they are being used. Where success has been most apparent, has been in cases where teaching is transformed through the use of computer technologies and where learning is happening in ways that were impossible or difficult without the use of these technologies. "Education can be transformed using ICT which brings new capabilities and capacities to learning. For example, ICT has the potential for enabling teachers and students to construct rich, multi-sensory, interactive environments with almost unlimited teaching and learning potential" (Balanskat et al., 2006, p. 12)

"Researchers are just now understanding how much greater the payoffs can be when digital-learning programs combine specific academic content with lessons from cognitive science and developmental psychology on how children learning in those subjects" (Viadero, 2007, p. 1). Computer use needs to go beyond low-level tasks such as students being able to demonstrate understanding of how to operate the various technologies with proficiency, to tasks that encourage more advanced learning by actively engaging students in learning, by releasing of agency from teachers to students, and through collaborative knowledge building around authentic or ill-defined problems. According to Dunn (2007) the best uses of computers gain learners' attention, engage learners through productive work, increase learners' perceptions of control, help learners visualize problems and solutions, link them to information resources and to learning tools, encourage shared intelligences through collaborative and cooperative learning, and encourage **higher level thinking**. Using an **inquiry** approach to learning with computers can be an effective way of creating a learning environment that places less emphasis on acquiring and presenting information and more on constructing knowledge, making meaning, drawing on personal life experience, and taking responsibility for learning.

The merging of technology and **constructivism** offers many possibilities for framing the design of such innovative learning environments.

HOW CAN CONSTRUCTIVIST LEARNING THEORY HELP TEACHERS TO DESIGN MEANINGFUL, COMPUTER-ENHANCED LEARNING ENVIRONMENTS?

Ferdig (2006) identifies the importance of "tying innovation to learning theory to create authentic and engaging activities for students" (p. 750). Research on effective integration of computer technologies in schools points to uses that support constructivist learning principles (Jonassen, Howland, Moore, & Marra, 2003). Constructivism is a theory about how people learn in which learning is not just about acquiring more knowledge but rather "it's the mental act of reformulating what we thought we knew into something new and different...Learning occurs through conceptual change" (Brooks, 2003, p. 13). This conceptual change occurs through an active and social process. The new learning always begins with and builds upon the learners' previously stored knowledge; as the learners elaborate upon and interpret the new information, their initial ideas are reshaped, and misconceptions in prior knowledge can be addressed through the formation of alternate conceptions (Tarhan, Ayar-Kayali, Urek & Acar, 2007). They are routinely asked to apply knowledge in diverse and authentic contexts, to explain ideas, interpret texts, predict phenomena, and construct arguments based on evidence (Windschitl, 2002). Learning occurs most effectively when it is situated in experiences that are authentic and meaningful to the learner and when they engage in task-oriented dialogue with one another. **Constructivism** as a framework for using computer technologies in the classroom has been advocated now for over a decade, but adoption has been slow. One of the reason is that it requires a significant shift in thinking about teaching and learning for many teachers from knowledge instruction to knowledge construction. Teachers who support this view recognize the importance of the active involvement of their students in learning and the need for a learning environment that encourages students' independent exploration of ideas. Smith, Clark and Blomeyer (2005) see the greatest benefits in "constructivist approaches that use interaction within a situational context to encourage learners to think and reflect while constructing their own personal meaning" (p. 11). However, teachers need to remember that the technology does not teach students, but rather the students only learn when they construct their own knowledge and think and learn through their experience. The computer is simply a tool that can assist students in their knowledge construction.

Technology use that is shaped by constructivist learning principles supports a more student centered, **inquiry** oriented approach to teaching. What is needed in classrooms are technology uses that help students to build knowledge and develop higher order thinking and problem solving skills by providing opportunities for them to think critically and analytically about information and represent their new understandings in multiple ways in an engaged setting (Marlow & Page, 2005). According to active learning principles, which emphasize **constructivism**, students must engage in researching, reasoning, critical thinking, decision making, analysis and synthesis during construction of their knowledge" (Tarhan, Ayar-Kayali, Urek & Acar, 2007, p. 286). Ferdig (2006) identifies five components of a social constructivist innovation design: authentic, interesting and challenging academic content; a sense of ownership by the learner; active participation, **collaboration** and social interaction; opportunities for creation of artifacts in a variety of ways; and publication, reflection and feedback (p. 750). Teachers also need to recognize that the four classroom walls no longer bind learning. "When children collaborate, they can and do scaffold each others' thinking" (Ferdig, 2006, p. 751). Every classroom has the potential to be a global learning environment. In this way, computer technologies can help to bridge the gap between the artificial world of school and the outside lives of young people by engaging then in projects that investigate real world issues, that draw on multiple perspectives and that encourage **collaboration** with experts and other students from around the world. Such global collaborative activities with peers in classrooms around the world can help to promote understanding and appreciation of multiple perspectives and encourage students to become global thinkers (Boss & Krauss, 2007).

Thus, constructivist uses of computer technologies need to provide learning opportunities that are based on authentic tasks and environments and include opportunities for exploring and doing as well as for feedback and reflection. These learning environments should be learning spaces in which students have control over the learning activities and are able to use a variety of information resources and tools to solve problems. The i**nquiry** should begin with students' prior background knowledge and experience, and engage them in creatively applying the resultant new knowledge. This learning environment should represent as much as possible the complex real world of problem solving, however, students need to be taught the skills to work in such environments. This is where a more structured type of learning environment such as **problem based learning** can provide initial assistance in developing the requisite skills by providing a guided process.

What is problem based learning and how it is an example of a learning environment based on constructivist learning principles?

In order to prepare students for today's' complex world, some schools engage students in problem-based learning... trying to hone the students' skills in applying what they learn to the kinds of problems they are likely to face. (Sternberg, 2008, p. 14)

Problem-based learning (PBL) is an instructional model that exemplifies constructivist learning principles (Ochoa & Robinson, 2005). One of the main characteristics of problem-based learning is situating the learning in the examination of authentic, real-life problems and questions of relevance to the learner in order to engage them in the learning. Rather than 'teaching' the student in the sense of presenting or even assigning information, the goal is encourage student driven **inquiry** in which they activate their prior knowledge and investigate the problem from a number of different perspectives in order to develop equally viable alternative solutions to the problem (Ochoa & Robinson, 2005). "Teachers who value thinking and habits of mind would ensure that students confront the problem with a questioning attitude, arm themselves with attendant data, explore alternatives to the status quo, and predict the consequences of each of those alternatives" (Costa, 2008, p. 21). Learning abstract ideas in this way becomes more concrete and realistic for students (Frazier & Sterling, 2008). Effective PBL environments also involve communication and c**ollaboration** that require students to articulate their ideas in ways that strengthen and assist the knowledge construction process as well as activities that encourage the learners to reflect on their learning. Organizing content around significant questions or problems can also assist students in developing higher order thinking skills, flexible understanding and lifelong skills (Ruiz, 2008).

The teacher in PBL does not teach the students what they should do or know and when they should do it or go about learning it. Rather the teacher is there to support the students in developing their critical thinking skills, self-directed learning skills, and content knowledge in relation to the problem. The teacher should acknowledge and support the students' thinking rather than impose structure on it but should also provide experiences that challenge that thinking. Initially the teacher needs to determine what the key concepts and procedures are that the child needs to know and then design a learning experience that requires students to use the that information in authentic tasks. Scaffolds also need to be built in to help students to organize and represent what they know as to provide the teacher with opportunities to probe students' knowledge and thinking skills. The **inquiry** needs to focus on using information as a means to develop information-processing skills and problem solving skills.

Computer technologies can be effective vehicles for introducing problems for student investigation because they "allow students to experience a shared context in which they engage in sustained thinking about complex problems and engage in interpretive learning experiences" (Hmelo-Sivler, 2004). **WebQuest** and Web Inquiry Projects are two examples of how online learning environments that are problem based can be designed.

HOW IS A WEBQUEST AN EXAMPLE OF A PROBLEM-BASED LEARNING APPROACH TO TECHNOLOGY USE?

A **WebQuest** is one example of how to design Internet-based learning experiences that promote **digital literacy** as well as the development of essential **higher level thinking**, problem solving and communication skills. There is a growing body of literature on the value of **WebQuests** as an instructional approach to integrate structured **inquiry** and the use of technology (Hicks, Sears, Gao, Goodmans & Manning, 2004). A **WebQuest** is an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web (Dodge, 2005). **WebQuests** are designed to efficiently use learners' time, to focus on using information rather than looking for it, and to support learners' thinking at the levels of analysis, synthesis and evaluation (March 2004; Dodge, 2005). Such a use of the Internet supports a view of students as active creators and shapers of their own knowledge who are able and willing to think for themselves. Through a **WebQuest,** students can actively explore issues and problems from a number of different perspectives, as well as searching for solutions and making moral and ethical decisions about real contemporary world problems. In an authentic **WebQuest** there is no single correct answer. While engaged in the **inquiry** through a **WebQuest,** students are constructing their own personal meaning about the problem under investigation.

The rationale for using a structured **inquiry** approach such as a **WebQuest** design can be traced back to Bruner's cognitive development theory. For Bruner, the most important outcome of cognitive development is thinking and the process that students undergo to acquire knowledge, not the product (Bruner, 1966). Bruner's discovery learning and **inquiry** teaching methods envision the learners creating their knowledge by "rearranging or transforming evidence in such a way that one is enabled to go beyond the evidence so assembled to additional new insights" (Bruner, 1961, p. 22). This requires an activity structure that scaffolds learners' experience so that they must move beyond simply finding information to using that information to think through and resolve a problem or issue. Also, the question posed to students cannot be answered simply by collecting and spitting back information. A well designed **WebQuest** requires students to transform information into something else. Some of the thinking skills analogous with **WebQuests** are "comparing, classifying, inducing, deducing, analyzing, constructing, abstracting, and analyzing perspectives" (Norton & Wiburg, 2003, p. 180).

WebQuests have been used successfully to develop subject specific content in middle and high school social studies (Hung 2004; Leite, McNulty & Brooks, 2005; Lipscomb, 2003; Stickland, 2005); creativity in art (Kundu & Bain, 2006), conceptual understanding in elementary math

(Orme & Monroe, 2005); thinking skills (Murry, 2006), with at risk students (Wilson, 2006); and ESL students (Goodwin-Jones, 2004); and for developing reading and literacy skills (Ikpeze & Boyd, 2007). "Using a WebQuest can help to bring reading alive, address essential questions that bring meaning to learning, engage in information processing, problem solving, **collaboration**, alleviate the concern of how to address reading needs of all students, taking on role- meet individual needs and differing learning styles" (Teclehaimanot & Lamb, 2004).

WebQuests can also enhance students' communication skills as many involve working in cooperative groups and role-playing. Working either independently or in groups, the students explore an issue or problem in a guided and meaningful manner. Some **WebQuests** have the students take on roles that help to make the group work together more efficiently and effectively. These roles can include a group leader, recorder, communicator, encourager and evaluator, among others. Other **WebQuests** have the learners assume the roles of particular players in a role-playing setting where they access, analysis and synthesize the information provided from the perspective of that player.

The most authentic **WebQuests** engage students in perspective taking on a particular problem or issue. Students investigate the context and the issue from an individual's perspective in order to build a better understanding of the person, the event and the setting. The goal is for students to use the information collected to construct an argument based on evidence. They then publicly share their findings with the class and the class tries to come to some kind of resolution to the problem under investigation. This resolution may mean arriving at class consensus or if there is a conflict of resolutions, then agreeing to disagree. Role-playing can be particularly beneficial for teaching students the importance of perspective taking when problem solving. Here is where **WebQuests** have the greatest potential for addressing the multicultural literacy aspect of **digital literacy**. Investigating problems from a number of different cultural perspectives can help learners to better understand the wide diversity of views on any one issue as well as the important cultural foundations of those views. This can lead to learning to respect and appreciate diversity.

WebQuests and **problem based learning** fit well together as they both address constructivist learning principles, critical thinking, **scaffolding**, learner motivation, cooperative learning and authentic assessment (Levine, 2002). Both **WebQuests** and problem based learning encourage **higher level thinking** including analysis, critical thinking and creative thinking; both include a introduction that sets the stage and provides some background information; both place students in a scenario where they must solve a fuzzy problem; both actively engage students in the learning and empower them to determine the outcome; both have no one right answer; both require compiling information from a variety of sources in order to arrive at a solution; and, both use authentic assessment strategies such as rubrics. Where these two strategies differ is in how structured they are and in who imposes that structure. **Problem based learning** is less structured than a **WebQuest** and provides the students with a larger decision making role in terms of defining the problem to be investigated, setting the conditions for resolution, determining strategies for addressing the problem, deciding on the roles to be taken and the end product of the investigation, and in selecting the resources to be used.

WHAT ARE THE COMPONENTS OF A WEBQUEST?

Usually a **WebQuest** consists of the introduction, task, process, resources, evaluation and conclusion. The first part, the introduction, lays out the task or the problem to be investigated, provides some background information and acts as a motivator to get the students interested in the activity. The task outlines the overall challenge the students will be engaged in and explains what they will be doing to represent what they have learned from completing the **WebQuest**. The task also provides the focus questions that frame the investigation and facilitate the learning process. The process provides a description of what needs to be done in order to accomplish the task in a step-by-step fashion. Here, students are usually assigned roles or provided with differing perspectives on the issue or problem being investigated. The resource section provides information sources that are needed for solving the task. Most of the resources used for the **inquiry** are other Websites that have been vetted by the teacher and linked directly to the **WebQuest**. Many **WebQuests p**rovide direct access to individual experts, current news sites and searchable databases for information sources. The evaluation section provides information for students on how they will be assessed. The assessment tool often included is a rubric for providing feedback on the outcome of the i**nquiry**. Other formative types of assessment can be used throughout the **inquiry** including personal reflective logs, skills checklists, and self and group feedback on the effectiveness of their group work. The conclusion brings closure to the **WebQuest** by reviewing and summarizing the learning from the experience and often challenges learners to extend their learning in new ways.

WebQuests can be either short term, on the average one to three classes, with the goal of acquiring and making sense of new information or longer term in which a student analyzes a body of information, transforms it in some way and demonstrates an understanding of that information in a public way. Longer-term **WebQuests** can take anywhere from a week to a month (Norton & Wiburg, 2003). Throughout the **WebQues**t, the teacher acts as the facilitator checking to see that students understand the role that they are to take and that they stay on task.

WHERE CAN WEBQUESTS BE FOUND?

A **WebQuest** can be chosen from a series of pre-designed **WebQuest** collections [see <http://Webquest.org/index.php> or < http://www.kn.att.com/wired/fil/tips/Webquest_instructions.html >] or one can be created by the teacher to address a specific topic of study. The latter allows for more active student involvement in deciding what problem they might like to investigate and in designing an interesting and relevant learning experience around that problem. An example of a pre-designed **WebQuest** from one of the databases mentioned earlier entitled "Does the Tiger Eat its Cubs" [http://www.kn.pacbell.com/wired/China/childquest.html] explores the way children in orphanages in China are treated.

In this **WebQuest,** students investigate the question "What's the truth about how children are treated in China?" They are directed to investigate the question from a number of perspectives. They are divided into three teams. One team reads international news reports, another reads responses from the Chinese people and a third examines the government of China's position as stated in China's One Child Policy. The class then comes back together and discusses their findings with the challenge of arriving at consensus decision on the issue. The culminating activity is to write a letter to the government expressing their opinion on what they feel should be done about the situation.

In the **WebQuest**, Children of conflict [http://www.accessola.com/osla/bethechange/Webquest/conflict/index.html], students work in teams as part of a task force to investigate how conflict affects children in different parts of the world. After researching their particular areas, the groups come back together to present their recommendations to a special parliamentary committee to decide what Canada should do to help to protect children around the world.

DNA for Dinner **WebQuest** [http://dnafordinner.blogspot.com/] engages students in an **inquiry** about the issue of genetically altered food. The issue to be investigated is "Should genetically engineered food crops be specifically labeled for consumers and why." Using the resources provided, students are to read up on the issue and then draft a law based on their investigation. They are then encouraged to email a representative in the federal government detailing their investigation and their concern over the issue and explaining their proposed solution. A **WebQuest s**uch as this one is an example of how the learning activity can be designed to increase students' motivation to want to learn by connecting what is learned in school to real world experiences.

WebQuests can also be a powerful way for students to be immersed in historical events and to have the opportunity to work with historical documents. In the Scrooge for Mayor **WebQuest** [http://www.coollessons.org/Dickens.htm], students work in teams to develop a campaign proposal for Scrooge using information about labour, education, industrialization and quality of life issues in nineteenth century England as represented in Charles Dicken's work of fiction "A Christmas Carol". Each campaign team is made up of a team manager, research analyst, public relations person and political strategist. Students are directed to focus on how Scrooge's viewpoint on daily life in London will need to change and what solutions to London's problems and programs he will need to support in his run for mayor. Each person on the campaign team is responsible for writing an article for a newspaper describing what they found out including what life was like in the area in the 1840's, the conditions that made it necessary to bring about change, what changes were proposed and how those changes would better things as well as an editorial on the topic "Is the industrial revolution a good thing?" The team also is directed to create a campaign poster, a pamphlet and a PowerPoint presentation that are to be used to communicate their ideas to Scrooge. This **WebQuest i**s an excellent example of how **WebQuests** can be used to integrate various subject areas in meaningful ways. It could be used to address the learning outcomes of social studies, reading, language arts and science.

In the Ancient Egypt **WebQuest** [http://www.iWebquest.com/egypt/ancientegypt.htm] students take on a series of missions to learn about King Tut, early Egyptian daily life, and the study of archeology.

Using the Middle Ages Storytelling Quest [http://www.iWebquest.com/middleages/Default.htm], students learn about the history of the Middle Ages then create their own story to teach their peers what they have learned about this historical time period.

Some WebQuests encourage students to take on cooperative learning roles to make their group work more efficient. The Big Wide World **WebQuest** [http://www.kn.pacbell.com/wired/bww/index.html] is an example of one that combines cooperative roles and focus topics to engage primary students in an investigation about their world. The "A "No-bullying Proposal" **WebQuest** [http://www.gecdsb.on.ca/d&g/nobullying/index.html] involves children in role taking from different perspectives on the issue of bullying. The groups then come up with a plan for how to address bullying in their school.

As well as selecting from thousands of predesigned **WebQuests**, teachers can design a **WebQues**t to meet their own personal needs using available templates [see for example < http://Webquest.sdsu.edu/LessonTemplate.html.]. Students can also be encouraged to try developing their own WebQuests and sharing them with classmates. A database of sample student developed WebQuests can be found at the ThinkQuest Library site [http://www.thinkquest.org]. Having students create their own WebQuests challenges them "to explore a topic, summarize what the most important events or facts are in relation to the topic, and then put together the links and questions or other students to follow" (Whitworth &

Berson, 2003, p. 480). When students engage in creating their own WebQuests, it can also enhance the development of their critical, creative and **higher level thinking** skills. The two Websites noted previously provide templates that students can use for creating their own quests.

WHAT ARE SOME OF THE LIMITATIONS OF WEBQUESTS?

The **WebQuest** approach is intended to capitalize on the possibilities provided by the Internet for guided **inquiry** learning while eliminating some of the disadvantages such as time wasted looking for resources, learners accessing inappropriate resources, and the lack of sufficient experience with the research process (Milson, 2002). There are some limitations to using WebQuests, however, that teachers need to be aware of. Maddux and Cummings (2007) caution that "simply because a lesson is cast in a **WebQuest** format is no guarantee that the lesson makes use of cooperative learning, advanced organizers, **scaffolding, problem-based learning**, nor does it guarantee that these concepts and techniques are effectively, or even merely competently, applied in a way that is consistent with the huge literature base underlying each of them" (p. 121). One problem is that not all **WebQuests** encourage **higher order thinking** and must be carefully scrutinized in order to assess how well they accomplish this. Many **WebQuests** are merely designed as fact-finding exercises that do little to engage students in problem solving. No attempt is made to engage students in role taking or learning to view problems from multiple perspectives. Fewer still actually engage students in learning the important problem solving skills of conflict resolution, compromising or agreeing to disagree. Others lack clear direction to the user that can detract from the ability of students to take control of the learning experience.

There are a number of Websites that provide rubrics for determining the quality of WebQuests. [See for example, <http://bestWebquests.com/bwq/matrix.asp> and <http://Webquest.sdsu.edu/Webquestrubric.html >]. The criteria included in these assessments are: engaging opener; clear question and tasks; learner roles match the issues and resources; **higher level thinking** built in; opportunities for feedback provided; and a conclusion that ties in to the introduction, makes the students' cognitive tasks overt and suggests how this learning could transfer to other domains/issues.

Another limitation of **WebQuests** is that students are most often removed from the process of selecting resources on which to base their investigation. There is now more information than teachers, textbooks and the curriculum can dispense. Consequently, students need to learn the skills to become information managers themselves. New computer technologies have much to offer teachers and students in terms of enhancing their information access, use and evaluation skills to encourage more effective and thoughtful consumption of information. As current information becomes easily accessible online, it is increasingly important that students have the opportunity to develop their critical analysis capabilities (Mason, Alibrandi, Berson Diem, Dralle, Hicks, Keiper & Lee, 2000). Also educators are warned not to simply rely on Internet filtering software but rather to focus on teaching students critical thinking skills so that they can learn to make informed decisions and judgments about the information they encounter on the Internet (Whitworth & Berson, 2003, p. 480). The use of such filtering tools can also be a problem as many sites that would be relevant to the study of a topic, such as war and conflict, would be inaccessible to students.

Locating useful and accurate information on the Web can be a struggle for students. The abundance of things to access via the Internet can cause students to be easily side tracked and spend a great deal of time off task. Information gathering can easily become a mindless exercise in which quantity overrides quality. This sort of information-gathering exercise does little to promote deeper thinking and understanding. Students need to be instructed in and have opportunities to practice how to critically examine and make informed choices about the information they are accessing. Critical information literacy skills need to be carefully taught and monitored to ensure students are developing proficiency in their use. In addition to learning the skills of locating and evaluating information on the Web, students also need to learn how to select relevant pieces of information and synthesize and organize it in order to apply it to the learning activity and communicate it to others.

Because there is an inclination to accept the computer as an authority and view the information accessed as the "truth," students need to be taught to recognize that the information on the Web represents a particular viewpoint, as does any other resource. They need to be encouraged to conscientiously use critical thinking skills to make both appropriate and ethical choices when using computer-generated information. Students need to be taught how to apply the skills of actively interpreting the information provided, drawing conclusions from data, seeing several points of view, distinguishing fact from opinion, and finding meaning in information, as they interact with digital technologies. In order to develop students' critical thinking skills, they should be taught to look for authorship/source, objectivity/biases, and validity of content, bibliography/reference links, currency and quality of writing. Questions such as the following can be helpful for students and teachers to use in judging the effectiveness of Websites:

- Where did this document come from and how reliable a source is it?
- Is the information presented objectively or with an obvious bias?
- How current is the information?
- How comprehensive is the coverage of the topic on the Website?
- How trustworthy is the data provided and how accurately does it depict the phenomenon?
- Does the site deepen my understanding of the topic?
- How useful is the site to me in assisting with the **inquiry**?

Critical literacy skills need to be carefully taught and monitored to ensure students are developing proficiency in their use. Children need to be instructed in and have opportunities to practice how to critically examine and make appropriate, ethical and informed choices about the information they are accessing. They need to be taught to recognize that the information on any Website represents a particular viewpoint and that it is important to examine several points of view on any issue. They also need to be taught how to distinguish fact from opinion.

A third limitation is that **WebQuests** lead students through a **scaffolded inquiry** experience that specifies the task, the roles and perspectives to be taken, the resources to be used and the guides for organizing the learning with little opportunity for the students to set the direction and plan for the investigation. Being heavily **scaffolded**, **WebQuests** prevent learners from participating in higher-level **inquiry** activities (Molebash, Dodge, Bell, Mason & Irving, n.d.). While these initial scaffolds are very important for helping children to develop problem solving strategies, there needs to be opportunities for releasing some of the control into the hands of the learners. Molebash and Dodge (2003) note that the support of the **WebQuest** can be removed in stages by allowing more flexibility in how and what student are to produce in the task, by gradually providing fewer URLs and expecting the learner to find more, by gradually removing the **scaffolding** such as note taking guidelines, information organizing structures, writing prompts, etc., and by putting more resources in the conclusion for learners to explore on their own later.

WHAT ARE WEB INQUIRY PROJECTS?

In order to promote higher levels of **inquiry** in the classroom, less specific guidance can be given to students. **Web Inquiry Projects** (WIPs) are one example of a way to extend the **WebQuest** idea beyond structured **inquiry** to more open **inquiry** that promotes **higher levels of thinking** and student engagement. **Web Inquiry Projects** are "open **inquiry** learning activities that leverage the use of uninterpreted [primary source] online data and information" (Molebash, 2004, p. 2). Unlike **WebQuests**, which provide students with a procedure and the online resources needed to complete a predefined task, **WIPS** place more emphasis in having students determine their own task, define their own procedures, and play a role in finding the needed online resources. More often the **inquiry** is sparked by the interest of the students. The teacher's role is to "insert the necessary **scaffolding** at each stage in the process to ensure that students are successful" (Molebash 2004, p. 2). According to Molebash, **WIPS** have seven stages: a hook to capture students' interest, question generating, deciding on procedures for guiding the investigation, data investigation of possible online sources, analysis of data, findings reporting including drawing conclusions based on the evidence, and lastly the generation on new questions resulting from the investigation to encourage further i**nquiry**.

Numerous examples of **Web Inquiry Projects** can be viewed at http://edWeb.sdsu.edu/wip/examples.htm. In the **WIP** entitled "The AIDS Epidemic: Can It Be Stopped?" [http://edWeb.sdsu.edu/wip/examples/aids/index.htm], for example, students are presented with the following hook:

The HIV/AIDS Epidemic is still occurring today. Currently medical research in finding a cure for AIDS have not progressed beyond prolonging HIV before it turns into AIDS. Although we don't see HIV/AIDS in the news today, it is still a problem around the world. Many people feel that they are not at risk for contracting this disease, but it is important for individuals to realize that they may be at risk. The first case of HIV/AIDS was diagnosed in the United States in the early 1980's. When will the last case be diagnosed?

In order to address this challenge, students need to determine what investigative tools to use, what types of data they will need and how they will manipulate that data in order to predict an answer. As a part of their investigation they also conduct detailed research on AIDs in order to increase their understanding of the issues surrounding AIDs and HIV.

In another example, North American Perspectives [http://eprentice.sdsu.edu/F034/sjohnson/teacher_template2.html], students are hooked into the i**nquiry** through a series of questions that they are to answer initially from their own perspective then from "behind Native American eyes". They are encouraged to think of some questions related to this topic that they might like to investigate as well as being provided some teacher-initiated ones. There are some pre-selected resources provided but students are encouraged to locate their own as well. Some ideas for how to re-present their learning are made available but once again students are encouraged to come up with their own ideas too. Each of these examples allows for a greater degree of student control over the learning experiences.

CONCLUDING REMARKS

Attention to **digital literacy** has become an essential aspect of children's education for the 21st century. This chapter began by defining **digital literacy** as well as highlighting other important 21st century skills including **higher level thinking**, problem solving, communication and **collaboration**. Included under the umbrella of digital literacy are such skills as understanding how to operate a particular technology, knowing how and why technologies can be used, and recognizing the ramifications of their use. The research on best uses of technology for learning has identified a number of effective ways for infusing **digital literacy** skills and other technology outcomes throughout a child's educational experiences. Emerging from this review of the research is an acknowledgment of the learning theory of **constructivism** as a way of framing learning experiences with computer technologies. **WebQuests** and their extension, **Web Inquiry Projects**, are two approaches that have the potential to effectively model constructivist learning principles while also addressing **digital literacy**, thinking, problem solving and communication skills. What makes these approaches to technology use in schools most effective is the emphasis on student directed learning and active student engagement. The level of student control over the decision making about the learning varies from a lesser degree in the more structured **inquiry** usually found in **WebQuests** to a greater degree in the open **inquiry** of **Web Inquiry Projects**. Other essential features of effective technology use found in both **WebQuests** and **Web Inquiry Projects** that were identified were: a) **problem based learning** focused on real world authentic issues and questions of interest to students and, in the case of **WIPs**, generated by the students; b) a focus on **collaborative** learning both within and beyond the classroom walls; and, c) an emphasis on learning to manage information and to work with that information at a **higher level of thinking** and understanding. All of these features support the call for learning experiences that attend to **digital literacy** and to developing the thinking, problem solving and communication skills of today's learners.

KEY TERMS AND DEFINITIONS

Digital Literacy: The skills of information location and application including understanding how to use available evidence to assist in problem solving and decision making.

Constructivist Learning Theory: A learning theory that acknowledges the learner as the holder and creator of their own knowledge.

Inquiry: An approach to learning that directly engages learners in constructing their own knowledge and understanding.

Problem Based Learning: An approach to learning in which learners inquire into problems about important questions and issues that have no clear answers.

WebQuest: A Web-based structured inquiry approach to learning.

Web Inquiry Project: A Web-based open inquiry approach to learning.

This work was previously published in Handbook of Research on New Media Literacy at the K-12 Level: Issues and Challenges , edited by L.T.W. Hin; R. Subramaniam, pp. 403-418 , copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 5.21
The EduOntoWiki Project for Supporting Social, Educational, and Knowledge Construction Processes with Semantic Web Paradigm

Corrado Petrucco
University of Padua, Italy

INTRODUCTION

The Web is going to produce a revolution in learning and teaching: the debate on the role of ICT in educational processes leads to a reconsideration of how we deal with information and knowledge. The widespread use in educational contexts is also due to the ease with which learning resources can be retrieved and shared: for example, the recent introduction of learning objects means that the contents which reside in different e-learning platforms is easy to find and access. But knowledge is also deeply embedded in millions of Web pages. Nonetheless, searching for information on the Web is not a simple task and the great number of documents found using search engines, such as Google, is beyond the human cognitive capacity to deal with this information overflow. Teaching information literacy skills or stimulating collaborative information filtering that supports the discovery of resources in a way that is responsive to the context of users may help, but there is a need for more efficient cognitive tools to search, organize, and discuss information in order to codify it in shared knowledge structures.

In a more and more complex world we need support to think at a high level so the technologies let us develop strong knowledge structures that do not have the representational problems of the old schemas. An attempt in this direction is the Semantic Web: if we succeed in making the Semantic Web available and useful for education, it could revolutionize the way we think about teaching and learning with ICT. Our current research is aimed at the development, experimentation and evolution of an integrated

DOI: 10.4018/978-1-59904-845-1.ch026

learning environment called EduOntoWiki that is backed up by a semantic structure based on the active consent of communities of practice.

BACKGROUND

Current research suggest that it is not correct to assume that the introduction of ICT necessarily changes the way students learn. We have to acknowledge that the teacher plays a critical pedagogical role in creating the conditions for technology-supported learning through selecting and evaluating appropriate technological resources and designing learning activities (Galliani, Costa, Amplatz, & Varisco, 1999). We can distinguish between two approaches to ICT: a technology-centered approach and a learner-centered approach (Mayer, 2005). The former generally fails to lead to lasting improvements in education: looking back at the many predicted educational revolutions, in which the current "new" technology (radio, television, computer, multimedia, the Web) would have been the "killer" application for teaching and learning processes, we see that they failed to materialize (Cuban, 1986) and so was the case with the claims and worries, during the 1960s, that computers-as-tutors would replace teachers (Cognition and Technology Group at Vanderbilt, 1996). A learner-centered approach can, on the other hand, help students and teacher to learn and teach through the aid of technology with a focus on how ICT can be used as an aid to human cognition and consistent with the way the mind works solving complex tasks and dealing with today's information overflow. The quantity and kind of information students today need to assess has expanded exponentially in the last few years, due mainly to the World Wide Web and improvements in the capabilities of search engines. In this context, it is important to consider both student and teacher roles using a constructivist approach that can stimulate collaborative formalization and knowledge building.

SEMANTIC WEB AND ONTOLOGIES

The Web has arrived at an important epistemological crossroad and there is a need to integrate the current dialogic-informative model, which allows us to interact with people and search for documents on the Web, with a model based on the contextual knowledge domains within which we operate: the Semantic Web approach (Berners-Lee et al., 2001). Both models are strongly based on a learner-centered approach so the applied research, in particular in the field of ICT and educational technologies, is moving in two directions:

1. The development of solutions for information exchange, and in general, for intelligent knowledge management;
2. The development of a collaborative/cooperative approach to knowledge building.

The Semantic Web was coined by Tim Berners-Lee to refer to a vision of the next evolution of networks that can add meaning to the navigational context of the current World Wide Web. It is the new-generation Web that makes it possible to express information in a machine-interpretable form, ready for software agents to process, as well as to understand what the terms describing the data mean both on the syntactic and semantic levels (Hendler, 2001). An important role in the development of the Semantic Web is played by ontologies (Gruber, 1993). The term is borrowed from philosophy but it is used in a different and more pragmatic sense: they are an explicit specification of a conceptualization, that is, a formal description of concepts and relationships that can exist in a knowledge domain, that is intended as a knowledge base to be shared and re-used in the real world. These ontological structures will, for instance, allow us to no longer surf the universe of documents on the Web through hypertext links from text to text, but from concept to concept; or even to retrieve information in a relevant way without the "noise" that characterizes search engines. In order to achieve this aim, formalized languages have been created (XML, RDF) to mark texts semantically. These languages, which are able to codify knowledge through domain ontologies, can be easily understood both by humans and by ad hoc programs such as semantic browsers (Dzbor, Domingue, & Motta, 2003) or by specific software agents.

The importance of ontologies has been recognized in different research fields, and even from an operational point of view the current application areas are different: from medicine to knowledge content standardization, from legal information systems to biological and geographical information systems, from e-commerce to natural language processing, and finally education (Devedzic, 2004). Our current research project is aimed at extending and integrating the construction and evolution of a semantic learning space that is backed up by ontological structures relative to educational sciences (Petrucco, 2003) based on an active consent of communities of practice.

THE EDUONTOWIKI PROJECT

The different training and background of those who contribute to educational theory, the different cultures they belong to, and the rapid development of scientific work today require the development of a series of shared conceptual schemas. It is important then to generate these schemas not as general principles but as justified, motivated, documented and finally usable schemas as control "criteria" of pedagogic discourse. As an ontology is basically a conceptual organizer of scientific discourse, it is a formidable support to hermeneutic work.

Within this context we developed the idea to build an ontology of education. The project takes into account the state of the art of educational research in Italy, France, Spain, Germany, England and Spain. The three thematic areas studied, at least in this first step of the project, are: *didactic planning*, *educational communication*, and *assessment* and *evaluation*. The ontology is "negotiated" in working exchanges and dialogical moments in order to develop a circularity of information flow within the virtual community of the experts involved in the project and other actors participating.

The project has been developed with the immediate aim of building an integrated semantic learning environment called "EduOntoWiki" (http://multifad.formazione.unipd.it/eduonto), a wiki-based environment where it is possible to construct, discuss, and contextualize ontologies suitable for describing the actors, processes and technologies of educational sciences. A wiki was chosen because it enables easy and immediate insertion, modification and sharing of texts and materials by a community of users (Wikipedia is a good example) and because it gives freedom over the knowledge creation process to users. The recent promising research in the application of the semantic Web to wiki software (Campanini, Castagna, & Tazzoli, 2004; Hepp, Bachlechner, & Siorpaes, 2005; Scaffert, Gruber, & Westenthaler, 2005) confirm this decision.

Indeed, our initial vision conceived the instrument as a tool to help in the creation of an ontology and the description of a specific knowledge domain mediated by a discussion within a community of practice. To be really useful an ontology requires the active consensus of a committed community of practice in a knowledge domain (Domingue, 1998; Trentin, 2004) as experts of do not always completely share the same categorizations, interpretations and distinctions. Often this is not only because of the reciprocal irreducibility of fundamental theoretical orders, which is both physiological and necessary, but rather because of the confusion created by the different meanings given to "key" terms in the discipline in question.

If it were possible to have an "ontological" reference model with shared lexis and semantics, as regards both terms and their relations, this would probably help to reduce conflicts which arise from misunderstandings and incomprehension. Ontologies created in this way would also have a significant side-effect for all the actors involved: first of all the definition of a common lexis (Wenger, 1998), then a strong push towards the conceptualization of tacit knowledge, and finally the sharing of a metamodel in which processes, knowledge and relations are shared. Defining ontologies which support educational applications based on the Web is therefore no simple task, above all because of the difficulty in formally conceptualising a domain which has always played on the idiosyncratic interpretation of each philosophical/pedagogical approach.

Ontologies would be useful not only to the academic community, but as far as their didactic use is concerned, we can think of an ontology or a series of "educational" ontologies, that could be used and discussed by students, teachers, and people interested in the real world of applications and training contexts. This "open" ontology paradigm can offer considerable advantages. For example, it could provide a medium which would foster the sharing of the basic knowledge in a discipline and a place where students could easily find educational resources (learning objects) with a strong context relation to the subject. Today the learning objects paradigm means that the contents which reside in the different systems used in e-learning platforms, need to become reusable, accessible and interoperable. Each object therefore needs to be described beforehand by others through unambiguous formalisms (so-called LOM, learning objects metadata) so that people can retrieve them more easily. But this retrieval paradigm is often wrong: the meaning of the metadata must be shared by most communities of users possible and this is not the common case. The practice of describing resources may at first appear to be simple and straightforward, however, when a system of description is analyzed deeply it becomes evident that it is actually ambiguous. The use of metadata presupposes not only a set of logical relations but also a specific vocabulary generally agreed upon by a linguistic community (Downes, 2004). Ontologies, integrated with social tagging processes (i.e., folksonomies) (Mathes, 2004), could indeed offer a strong support for solving this problem because every learning object would be *embedded* in the structure of the ontology itself; in this sense there is a side-effect that consists of the collaborative setting up of a learning object repository that uses the ontological base for "intelligent" consultation. Learning objects have always existed in teaching: in their practice, educators operate within a deconstruction and reconstruction process of materials and resources, but what is missing is often a conceptual and disciplinary framework to go back to, which, in today's world, could be easily accessible and consultable through the Web. It is precisely this that the various domain ontologies could provide.

The wiki interface of the ontologies is well suitable for developing a constructivist environment, where people of a learning community can add and modify the concepts dialogically (Souzis, 2005). If we then assume that the learning process is never confined to the materials used in an online course, but that it is also fruit of the interaction among the members of the group, with the wiki-based ontologies we provide a *scaffolding* (Devedzic, 2004) which will facilitate communication and the construction of meaning among all the actors involved (academics, teachers, tutors, students) and at the same time represent the structure and contents of the discipline.

FUTURE TRENDS AND DEVELOPMENTS

As ontologies in EduOntoWiki will be the result of the active involvement of both a community of practice of academics and actors from different educational fields (teachers, students and trainers), the social/relational aspect which turned out to be increasingly significant in the course of this research, led us to systematically further the study of the relationships within a community, as well as between different communities, in relation to the knowledge construction process supported by the wiki-based software. We want to verify how this environment can ease knowledge construction and formalization as "instance" from different communities of practice interacting together. In fact, the direction that the most promising, current research is taking involves the study of so-called "complex constellations of communities of practice" (Wenger, 2004). This definition has been used to describe the special relationships which unite various communities and render them permeable in such a way that they can reciprocally share knowledge, contextualizing, and enriching it with new meanings, thus favoring creative solutions to complex problems.

On the basis of these premises, we will seek to verify whether a social theory of learning can effectively lead to the overcoming of rigid borders between training/educational systems, work environments and social activities. In this sense, we can try to "free" learning so it is no longer seen to be linked to a specific area or moment of one's life, but actively constructed in the inter-community interactions of a lifelong learning continuum.

What will be investigated in particular are the negotiational interrelations between people who, in various forms, are members of different communities, people who share an active interest in all training environments and who bring valuable examples of "good practice" even if they belong to different work contexts. This aspect, led us to expand a new learning dimension, aimed at stimulating reciprocity, transferring and recontextualization processes, insofar as learning is recognized as a social/relational process, and the multiple contexts where learning takes place that becomes a precious alternative representation (Lave, 1988), effectively expressed by the learning subjects by means of a narrative description (Bruner, 1996) that a rigid codified ontology formalization would, on the contrary, risk penalizing. Narrative is used in education and training contexts to motivate and to illustrate, the reason for this is that the cognitive structures we use to understand the world around us are similar to the cognitive structures we use to understand narratives. It is assumed that the interaction, comparison and reciprocal recognition of the different communities involved will succeed in triggering off a virtuous process of crossfertilization able to transfer skills, processes, and models.

An important challenge highlighted by a close examination of international research on this theme, is that inter-community relations are not easy to manage or formalise since the members can only count on relatively limited shared meaning and practices (Friesen, 2002). Interoperability among communities, which our EduOntoWiki environment wishes to foster, is thus closely linked to a negotiation of meanings, identities and roles. Identity and roles for example, can be formalized using the semantic standard FOAF, (friend of a friend) while other important personal relations are more difficult to express. Maybe the only way is to include the innovative approach of the folksonomies (Petrucco, 2006) and/or the creation of specific "instances" in the ontologies intended mainly as a narration of personal and contextual experiences lodged in a precise space, time and place. It is not by chance that social networking tools, such as LinkedIn, Friendster and Orkut, are now considered a necessary extension of the recent blog phenomenon. In fact, we intend to evaluate whether, and in what way, it is possible that this process of *narrative conceptualization* can lead from the formulation of "descriptive instances" to spontaneous formalization, on behalf of community members, of "normative instances", that is, knowledge models which can be reused in multiple experiential contexts for solving problems.

CONCLUSION

Our research group believe that the potential effects of the Semantic Web for the world of education and training, and in particular for e-learning, will certainly be positive, but only if governed by a strong pedagogical-methodological reference structure which facilitates integration of the new technological-semantic paradigm into the more recent social theories of learning. Given these assumptions, combining the Semantic Web with social software appears to be a natural choice: it can support the creation of semantically enriched content using simple interfaces and by allowing domain experts and novices, teachers and students to collaborate within rich inter-cultural communities, sharing their true life experiences. To conclude, while it is true that the EduOntoWiki project presents considerable challenges both on a technical-scientific and on a theoretic-methodological level as it attempts to integrate the most innovative instances of international research on the Semantic Web and on pedagogic research, we also believe that fast and complex contemporaneous social evolution necessarily requires adequate instruments able to interpret and manage it.

KEY TERMS

Communities of Practice: Communities of practice are groups that form to share what they know and to learn from one another regarding some aspects of their work. People in organizations often realize they could benefit from sharing their knowledge, in-sight, and experiences with others who have similar interests or goals. For the most part, this process of informal gathering and sharing of expertise is a voluntary.

Folksonomies: Folksonomies are bottom-up taxonomies that people create on their own, as opposed to being created and imposed by a group or institution such as by professional librarians using complex and lengthy rule sets (e.g., Dewey decimal system or Library of Congress index). Synonyms include folk categorization, social tagging, and ethnoclassification. They are grass-roots classification systems for data. The value in folksonomies is derived from many people adding their own tags. The more people tagging one object, the better, because it gives alternative ways of searching for and finding information.

LOM (Learning Objects Metadata): We can define metadata as "information about information", and a LOM is a metadata about a learning object that can refer to multimedia or digital educational resources. Sets of metadata are used to identify and meaningfully describe characteristics relevant to these resources, for example, the learning resource type, the intended end user, difficulty level, educational goal, and so forth. The Learning Technology Standards Committee

(LTSC) give rise to the IEEE LOM (Learning Object Metadata) 1484.12.1-2002 standard of educational metadata.

Ontologies: An ontology is a formal representation of knowledge about an area of interest. The part of the world conceptualized or described is called the "knowledge domain." Ontologies provide a vocabulary for representing and communicating knowledge domains and a set of relationships that hold among the terms in that vocabulary.

Semantic Web: The Semantic Web is an extension of the current Web in which information is given a well-defined meaning, better enabling computers and people to work in cooperation. The mix of content on the Web has been shifting from exclusively human-oriented content to more and more data content. The Semantic Web brings to the Web the idea of having data defined and linked in a way that it can be used for more effective discovery, automation, integration, and reuse across various applications. For the Web to reach its full potential, it must evolve into a Semantic Web, providing a universally accessible platform that allows data to be shared and processed by automated tools as well as by people. [W3C]

Social Network: A social network is a set of people or organizations or other social entities connected by a set of social relationships, such as friendships, coworking or information exchange. The connections between them may show specific patterns and can be represented by graphs. Recently many online social networking sites have begun to flourish with millions of users describing themselves in terms of who they are, what music they listen to, what books they read, and so forth, and trying to discover other people with similar interests.

Wiki: A Wiki is a collaboratively-edited Website that uses a software publishing tool. The distinguishing feature of wikis is that they typically allow all users to edit any page, with full freedom to edit, change and delete the work of previous authors. Collaborative knowledge creation is thus a central aspect of a wiki system. Wiki pages are accessible and usable at any time, and the content constantly evolves. The first wiki was created by Ward Cunningham, and the word "wiki" came from a phrase in Hawaiian—"wiki wiki"—which means "quick". It's quick because the process of editing is entwined with the process of reading. Both are done using a standard Web browser. Unlike most Websites, there's no need to edit a file, upload it to a Web server, then reload the original to check it.

Chapter 5.22
Modeling Best Practices in Web-Based Academic Development

Diana K. Kelly
San Diego Miramar College, USA

ABSTRACT

This chapter makes a case for the importance of preparing e-teachers by requiring them to have an experience as an e-learner. The chapter begins with a review of the challenges and criticisms of e-learning. Some of the literature indicates that e-learners have been dissatisfied with their learning experiences. Some academics have concerns about the rigour of courses offered through e-learning. The literature of academic development and e-learning is used to link theory with practice. The chapter provides examples of best practice in the preparation of academic staff for e-teaching. Two case studies of lived examples of e-teaching preparation are provided from a North American perspective. Future research directions are outlined, with research questions to be explored regarding the link between the preparation of e-teachers through e-learning and the quality of the e-learning experience for students.

INTRODUCTION

Academic staff in higher education are enthusiastic about getting involved in e-teaching, yet most are getting started with no experience as an e-learner. Experiencing e-learning from the learner's perspective is immensely helpful, if not essential, for effective e-teaching. Ideally, it would be best to experience a very positive and involving model of e-learning, which may be used as a model for one's own e-teaching. This chapter is a presentation of a lived example of academic development through e-learning.

The aim of this chapter is to make a strong case for the preparation of e-teachers through successful completion of a fully online programme to prepare for e-teaching. International examples of e-teaching programmes will be included, including lessons learned from participation in two North American Web-based e-teaching programmes: one generic programme (for anyone from any institution), and one programme offered by a university for new e-teachers.

DOI: 10.4018/978-1-59904-814-7.ch003

BACKGROUND

Whenever new or innovative teaching methods are used, it is normal for sceptics and critics to express concerns about the quality of teaching and learning, and e-learning has attracted some criticism. While some studies have shown “no significant difference” between learning outcomes in face-to-face classrooms and in the e-learning environment (Joy & Garcia, 2000), other studies have shown high attrition rates in e-learning, student frustrations with inexperienced e-teachers, and frustrations of e-teachers with poor student participation and learning outcomes.

While all of these criticisms cannot be directly linked to the quality of the preparation of the e-teachers, some of the frustrations of novice e-teachers show that preparation for e-teaching is a significant issue that does contribute to the quality of the overall teaching and learning experience for students and teacher.

Academic staff who plan to begin e-teaching usually need some professional development to provide an introduction to the new learning and teaching environment. According to a recent study in the United States, two thirds of 320 colleges and universities surveyed require academic staff to complete some training prior to teaching online (Lokken & Womer, 2007). Professional development for e-learning often takes the form of face-to-face workshops, one-on-one assistance and mentoring, and sometimes hybrid or blended e-learning experiences. The focus of some professional development is on the use of the technology, or on the development of materials to put up on a Web site for students. Some academic development programmes are also focused on the use of e-learning technology to enhance student learning.

The main point of this chapter is to consider the potential benefits of a professional development programme that is provided fully online. Some universities currently provide professional development preparation for teaching online through classroom instruction in computer labs or through blended learning formats. The premise of this chapter is that, while these approaches are useful, it may be even more effective for academic staff to have the opportunity to experience e-learning fully at a distance as their students will. This chapter will focus on the role of effective professional development fully through e-learning to prepare teachers for high-quality e-teaching that is focused on student involvement and learning. First the criticisms of e-learning will be explored to determine what needs to be done to improve the quality of e-learning. Second, best practices in professional development will be examined, including possible ways of translating these to the preparation for e-teaching. Third, research on the current practices in academic development for e-teaching will be explored. Finally, recommendations will be made for the improvement of the preparation of e-teachers in the future.

This chapter is not a research-based chapter, but rather a detailed review of the existing literature on the challenges of preparing academic staff for teaching in the online environment, and some of the best practices that are emerging in the field.

In this chapter, the terms *e-teaching*, *e-learning*, *Web-based learning*, and *online learning* refer to any instructional course component delivered using the Internet, whether provided fully at a distance or in a hybrid or blended format. E-teaching refers to the processes used by teachers, and e-learning refers to students learning online.

ISSUES, CONTROVERSIES, PROBLEMS

Several concerns are addressed frequently in the literature of e-learning: the quality and rigour of instruction, including learning outcomes; student persistence; and student satisfaction.

Concerns about the Quality and Rigour of E-Learning

There is a perception, particularly among those who have not experienced e-learning, that it is much less rigourous for learners and teachers than face-to-face classroom-based learning. A recent report from the Sloan Consortium (Allen & Seaman, 2006) notes that although perceptions of quality in e-learning have improved somewhat since 2003, only 62% of chief academic officers surveyed believe that learning outcomes are the same as face-to-face learning, and only 16% believe outcomes are superior in e-learning.

The highly quoted report *The No Significant Difference Phenomenon* (Russell, 1999) was a meta-analysis of research studies that showed evidence that the learning outcomes from e-learning were no different than learning outcomes in traditional courses. However, since then, others, including Phipps (2000) and Joy and Garcia (2000), claim that the original analysis was flawed and that cause and effect cannot be determined because the research did not control for extraneous variables. Joy and Garcia recommend that rather than looking at the use of technology as an issue to be debated, it is more important to focus on learning by considering this question: "What combination of instructional strategies and delivery media will best produce the desired learning outcome for the intended audience?" (p. 38).

In a meta-analysis of many studies of learning effectiveness in e-learning courses offered at a distance, Zhao, Lei, Yan, Lai, and Tan (2005) found that interaction is the key element that contributes to student learning outcomes. More interaction among students and teacher, including both asynchronous and synchronous interactions, was the most important element in many studies of e-learning.

Problems with Student Persistence in E-Learning

Student persistence in online distance learning courses is another concern. Although it is difficult to obtain accurate statistics on dropout rates, higher education officials in the United States estimate that student persistence is generally 10 to 20 percentage points lower in e-learning courses (Barefoot, 2004; Carr, 2000). A more recent study of over 300 colleges in the United States shows a much smaller difference in student retention in semester-length modules: 72% for distance learning and 78% for face-to-face modules (Lokken & Womer, 2007).

While theories on persistence in face-to-face learning emphasise engagement and social cohesion, Gibbs (2004) points out that an attempt to adapt these theories to the online environment have not been successful. However, according to one study, feelings of isolation, anxiety, or confusion can contribute to decisions to drop out of online courses (King, 2002). Several studies have found that students underestimate the workload of e-learning and will drop out when they feel they have fallen too far behind (Aqui, 2005). Jo Tait (2004) of the Open University (United Kingdom) explains that student persistence is difficult to address because there are many factors that may contribute to students' decisions to drop out. However, she also points out the important role of tutors in distance learning, and the need for academic development to teach in ways that enhance student persistence. One example of this comes from an introductory computer module at a community college in Tyler, Texas. The e-teacher, Emilio Ramos, reported that when he started holding regular chats and provided more interactive discussions for his students, his course completion rates jumped from 62% to 90%. Ramos says, "The key to having low attrition and successful completion in the online medium is the ability of instructors to keep the students engaged, and that requires quite a bit of effort from the instructor's point of view" (as cited in Carr, 2000).

Student Criticisms about the Quality of E-Learning

Some of the criticism of e-learning has come from students. In a large-scale study of students who have participated in Web-based distance learning in the United States (Noel-Levitz, Inc., 2006), students responded that the following areas needed improvement in e-learning: the quality of instruction, the responsiveness of e-teachers to students' needs, and timely feedback from e-teachers. Experienced e-learners would agree. After dropping out of an online astronomy module mid-semester, a student said, "It wasn't worth the headache. The instructor wasn't a bad teacher. He just did not have the experience with online courses" (as cited in Carr, 2000). The instructor was teaching online for the first time and had not set up the course materials and labs properly.

Other studies reinforce these findings, including a study of Canadian university students (Stodel, Thompson, & McDonald, 2006). When asked to compare their experiences in face-to-face classes with online classes, students expressed concerns about the quality of the online asynchronous discussions. Some felt that they were too drawn out, going over the same issues too many times. Others were unhappy with the flow of the discussion and felt that students were really just "checking in" rather than paying close attention to what others had already written on the discussion board.

Despite the criticisms about the quality of e-learning and the concerns about the consistency and rigour of e-learning, it is possible to address these concerns by preparing e-teachers more effectively.

SOLUTIONS AND RECOMMENDATIONS

To examine the solutions, it is important to first look at best practices for the preparation of e-teachers. Two case studies of e-teaching preparation will be described in detail as concrete examples of the best practices outlined.

Best Practice to Prepare for E-Teaching

In determining best practices for preparing for e-teaching, it is important to examine four dimensions of the preparation. First, how do novice e-teachers learn to teach online? Second, how can best practices in academic development for face-to-face teaching be translated into the preparation of e-teachers? Third, which methods of professional development are currently used in preparing academic staff for e-teaching? Fourth, what is the focus of the professional development programmes to prepare new e-teachers?

First, How do Novice Teachers Learn to Teach?

Those with no background in teaching and learning often try to reproduce what they have experienced as students. If they have seen excellent lectures, they will try to emulate them. If they have experienced small group work and lively discussions, they will try to create a similar learning environment for their own students. They often tend to use the teaching methods that best suit their own learning style.

How do novice e-teachers learn to teach online? If novice teachers tend to reproduce what they have experienced as students, what happens if they have never experienced e-learning? If they do not have a frame of reference or a prior e-learning experience to draw upon, it is very challenging to begin to teach online. This is confirmed in an article written from the perspective of a first-time online teacher. Using a reflective approach through teaching journals, student feedback, and analysis of online discussions, Yu and Brandenburg (2006) analysed several dimensions of a first-time e-teacher's experience. The issues and frustrations that were raised indicated a lack of experience in e-learning as a learner, and a significant lack of preparation to teach online. In particular, the importance of facilitating student interactions and collaboration was a lesson learned through hard experience. In a case study of another very frustrated novice e-teacher, Choi and Park (2006) outlined very similar issues and concluded,

If the new online instructor had had training regarding the pedagogical issues of online teaching and vicarious experiences through experienced online instructors, she could have been better prepared and had a different impression about online teaching. This implies that training for online instructors should be designed with more focus on the pedagogical issues of online teaching and on vicarious experiences with the actual online teaching rather than on technical issues. (p. 322)

The University of Hull developed a tutor training programme for e-teaching based on a model that started with face-to-face workshops, progressed to 4 weeks of online teaching observation, and ended with 12 weeks of online teaching practice. In their extensive evaluation of this programme, it became clear that one of the major issues was the lack of experience in e-learning as learners. The participants could only imagine what it might be like as an e-learner, and they only had a few weeks of experience as an observer (not learner participant). The programme evaluation also noted the importance of modeling practice in the tutor training programme that matched the group work and interactive discussions that would be expected of tutors when they were teaching (Bennett & Marsh, 2002).

Second, Which best Practices in Academic Development may be used Effectively in Preparing E-Teachers?

The following characteristics of academic development programmes are important to consider for long-term impact and positive changes to teaching practice: a long duration, social construction, a focus on content, an experiential model of learning, and reflection on learning.

Longer duration programmes are more effective than short-term workshops. Several studies have shown that activities for academic development that are longer in duration tend to have a more substantial impact on making changes to teaching practice over the long term (Hinson & LaPrairie, 2005).

The social construction of learning through cohorts is important for long-term impact on teaching practices. Tom Angelo (2001, p. 100) explains, "Faculty [academic] developers intent on change must engage their colleagues in constructing or adapting new, shared, contextually relevant concepts, rather than presenting faculty [academic staff] with imported prefabricated models for adoption."

Academic development programmes linked clearly to the content of teaching are more meaningful for teaching practice. When lecturers have opportunities to apply their learning to teaching in their own discipline, they are more likely to make changes to enhance their teaching. In a successful programme of professional development for online course development at Louisiana State University, participants moved from learning and practicing new skills in using the e-learning platform to applying the skills into their own courses (Hinson & LaPrairie, 2005). Another study of over 1,000 science and mathematics teachers found that professional development activities with a focus on content knowledge and active learning had the greatest positive impact on increases of knowledge and skills in teaching, which changed the teachers' teaching practices. In addition, those activities that were longer in hours of participation and spanned a longer period of time had the greatest positive impact (Garet, Porter, Desimone, Birman, & Yoon, 2001). Most lecturers consider teaching methods to be linked strongly with the discipline, so they are more likely to be accepting of ideas and advice on teaching from those within their own discipline. Those in a department who have a solid background in learning theory and teaching and learning methods can be very effective consultants to their colleagues. According to Maxwell and Kazlauskas (1992, pp. 356-357), "expert consultation by colleagues on specific teaching matters were among the most effective modes of development."

Experiential or situated learning is the notion of experiencing a model of teaching and learning to be used in a real-life situation. If learning is embedded in the context in which it will be used, it will be more meaningful to the participants (Brown, Collins, & Dugiud, 1989). Ideally, the learning experience should provide authentic situations and activities, process models, collaborative constructions of knowledge, and opportunities for reflection (Herrington & Oliver, 1995). Staff developers at Southern Cross University in Australia call their module a "staff immersion" programme that immerses participants in the role of online students, who learn about the potential for online interaction (O'Reilly & Brown, 2001).

Stephen Brookfield (1993, p. 21) explains the importance of becoming learners to learn about teaching: "I argue that regularly experiencing what it feels like to learn something unfamiliar and difficult is the best way to help teachers empathise with the emotions and feelings of their own learners as they begin to traverse new intellectual terrains."

By experiencing a well-designed and well-facilitated e-learning course about teaching online at a distance, new e-teachers understand from their own experience what a good e-learning experience feels like. The University of Southern Queensland drew upon the ideas of situated and experiential learning to develop a situated staff development model for e-teaching (Taylor, 2003). This successful model included awareness building for novice e-teachers experiencing the actual e-learning environment with authentic activities, a small amount of face-to-face training, online reflection, and peer mentoring.

Reflection on the learning experience and possible application to teaching must go hand in hand with experiential learning. Cowan (2003) points out that we learn from experience only if we also reflect upon that experience: "What have I learnt from that which will be useful to me in the future?" (p. 207) is a useful question for stimulating reflection on a learning experience. Cowan calls this "reflection for action," expanding upon Schön's (1988) model of reflective practice.

Third, Which Methods of Professional Development are used to Prepare for E-Teaching?

Whether teaching and learning occurs fully at a distance or in a blended format with some face-to-face meetings, academic staff must be well prepared to teach effectively in this new learning environment. This preparation often includes an orientation to the course management software, such as WebCT™ or Blackboard™, and usually takes the form of a face-to-face course or a series of workshops that include some underpinning learning theories, the use of features of the e-learning platform, and the development of materials to load to the course Web site. There are several examples of this type of workshop designed to prepare those who are new to e-teaching, including the Jump Start programme at Indiana University Purdue ("IUPUI Jump Start Program Prepares Faculty to Teach Online," 2006), the CampusNet online workshop provided by the University of Houston, Texas (Kidney, 2004), and the Xanadu project at the University of Turin, Italy (Trentin, 2006).

While these face-to-face workshops are helpful, they might not provide the same experience as an online e-teaching course. How will the new e-teacher learn what a good discussion looks like? How will teachers understand the experience of a new e-learning student if they have never participated in an e-learning module?

Blended or hybrid e-learning is the format of choice for some university professional development programmes, including the e-moderating course offered by the University of Glamorgan (Fitzgibbon & Jones, 2004). However, blended learning comes with the challenge of finding an appropriate time for the face-to-face sessions.

Some programmes are fully online self-paced tutorials. Prospective e-teachers are expected to work through the materials to learn to teach online. While this provides experience in using the course management software, and often gives prospective e-teachers a look at innovative possibilities for course materials and assessments, the self-paced workshops lack one of the most important aspects of e-teaching: the facilitation of online discussions.

Fully online e-teaching programmes offered at a distance include the e-moderating programme at the Open University, United Kingdom (Salmon, 2006), and the two case studies described later in this chapter. This model provides a comprehensive experience in e-learning for the prospective e-teachers and, if well modeled and well facilitated, provides a positive experience for future e-teachers to draw upon when they begin teaching online.

Fourth, What is the Focus of E-Teaching Programmes?

The focus of e-teaching programmes has been evolving. Some programmes still focus on the use of the technology for e-learning, including how to use various features of the specific e-learning course management software, such as WebCT™, Blackboard™, Moodle™, and so forth. As a part of this focus, novice e-teachers are most interested in learning how to develop materials for a module Web site with a content-driven focus when preparing to teach online. As Dianne Conrad (2004) noted in her study of novice e-teachers, teachers' overall concerns stemmed from their perception of their role as "deliverers of content." They appreciated the e-learning platform as a place to put more content to be accessed by their students. However, they did not seem to be concerned about issues of social interactions among learners, and facilitation and mentoring of learners. The participants in Conrad's study took part in face-to-face workshops and one-on-one mentoring sessions that focused only on the use of the technology for e-learning. While this is a necessary part of professional development for e-teaching, the professional development focus must go beyond a focus on technology and content.

A study of over 500 members of the Multimedia Educational Resource for Learning and Online Teaching (MERLOT) indicated that the focus of interest for e-teachers has shifted from technology skills training to enhancing skills in e-moderating for high-quality online learning (Kim & Bonk, 2006). Gilly Salmon's (2006) well-respected work in this field indicates that this is a crucial component in successful e-teaching. Using Vygotsky's "zone of proximal development" as a model, those who provide e-teaching workshops online can help the academic staff to develop their skills in facilitation by modeling behaviours in asynchronous discussions that will be more productive for their learning development, including questioning techniques that probe for deeper learning (Welk, 2006). Through this modeling, participants will experience the type of facilitation that will help them to be more effective facilitators of online asynchronous discussions.

To summarise, high-quality e-teaching programmes focus on the learning theories and principles that have been proven to be effective in face-to-face teaching, adapting them to the e-learning environment. The "Seven Principles of Effective Teaching," originally developed by Chickering and Gamson, were used by Graham, Cagiltay, Lim, Craner, and Duffy (2001) to provide a useful way of looking at the qualities of teaching that help students learn in the online environment. These seven principles include contact between students and teacher, cooperation among students, active learning, prompt feedback to students, time on task, high expectations, and diverse talents and ways of learning. By applying these same principles to e-learning, e-teachers can fine-tune their teaching practices.

TWO CASE STUDIES: MODELS OF THE FULLY ONLINE E-TEACHING PROGRAMMES

To provide concrete examples of model programmes to prepare e-teachers, two programmes are described (Kelly, 2000, 2002). Both programmes were provided fully online at a distance with no face-to-face meetings. This was an intentional part of the design to give participants the same experience that learners will have when they participate in a fully online programme rather than blended or hybrid learning.

The first case study describes a postgraduate-level certificate programme open to anyone in the world who has teaching experience in education, higher education, or in professional development in the business world. The second case study describes a programme that was designed specifically for Walden University to prepare tutors to work online at a distance with postgraduate students in the PhD in education programme.

The most important similarities between the programmes are the strong grounding in learning theory, a focus on facilitating active learning through asynchronous discussions and collaborative activities, and, most importantly, providing a relevant learning experience in context and allowing reflection on this experience.

University of California at Los Angeles: Online Teaching Programme

In 1999 I decided to update my skills as an academic and learn about online classes. Because my time was limited and my day-to-day schedule was somewhat unpredictable, I was happy to find a fully online certificate programme on teaching online offered by UCLA (University of California at Los Angeles, http://www.uclaextension.edu). The certificate programme consisted of five core modules and one elective module. The school recommends taking two modules at a time, so I started with the first two core modules: Introduction to Online Technologies and Developing Curriculum for Online Programs. Other core modules were Teaching and Learning Models for Online Courses, Internet and Online Teaching Tools, and Practicum in Online Teaching (a capstone course). I chose the module Multimedia Production as my elective module. Modules were offered in 4-week or 6-week periods in four terms each year. Taking two modules each term, it was possible to complete the certificate programme in three terms over 9 months.

Flexibility in Learning

Although there were clear starting and ending dates for each module, the time students put into the actual course work was entirely flexible. Almost all of the collaborative work and online discussions were asynchronous. Each module usually had 10 to 15 participants, and only those who were experienced teachers were accepted into this programme. Some were from very remote areas, and they were happy to participate in this online programme because they had no university within traveling distance.

People have often asked how much time this online programme required of me as an e-learner. My experience was that, as with any course, it depends on the student's level of interest and motivation. Students could spend as much time online and completing assignments as they wanted to, but on average, I probably spent about 10 hours per week on each module, and more when major assignments were due. Those 10 hours per course (20 hours per week for two courses) were spread out over lunchtimes, evenings, weekends, and generally whenever I had a chance to work on assignments.

International Participation

As a fully online programme offered at a distance, we had a very international group of participants from many parts of the world including Hong Kong, Saudi Arabia, Australia, Switzerland, and North America. This resulted in rich discussions with an international perspective. We learned quite a bit about educational issues in other countries and gained some new ideas. Having such broad international participation would not have been feasible if face-to-face sessions had been required.

Mandatory Student Orientation

After enrolling I received a welcoming e-mail from OnlineLearning.net, UCLA's online learning provider. It recommended ordering textbooks soon, and provided links to several places where textbooks could be ordered online. The e-mail also included information about how to download the necessary software from Embanet, the online course management system, which was a simple process.

Prior to the start of the first module, it was required that all participants complete a four-part online self-paced orientation to the Embanet software. There were dire warnings that those who did not complete the entire orientation would be removed from the module. Although this sounded a bit harsh, it soon because obvious that the online orientation to the software was absolutely essential to the experience. Students learned how to use the asynchronous discussion groups, submit assignments, participate in synchronous chat, go to the course resources, get help from Embanet, and so forth. Without this orientation and the easy availability of Embanet's technical-support team (by phone and e-mail), this fully online programme would have been very frustrating, if not impossible.

The Importance of Technical-Support Systems for E-Learners

High-quality e-learning is impossible without good technical support in place, ideally 24 hours per day, 7 days a week. If this is not possible, then it should be available at specified times when usage is highest, particularly on weekends and evenings. It can be incredibly frustrating if the course Web site crashes, especially when an assignment is due. Embanet had a habit of doing this periodically. Fortunately, Embanet had excellent technical support for major problems like a Web site crash or individual student problems such as software incompatibility. Students could e-mail or call the technical-support desk for immediate assistance with any problem.

Providing a Welcoming Learning Environment

As with any face-to-face class, introductions at the beginning of each module help students to become involved more quickly. Online learning is no different. Participants have a desire to make connections with other students, but the e-teacher must facilitate this. This initial interaction on the discussion board also helps e-learners get into the habit of checking in to the course Web site regularly to see if anyone new has added their introduction.

About a week before the module started, we received a welcoming e-mail from the e-teacher. She asked all of us to go to the course Web site and introduce ourselves, including our background, our interest in online learning, and what we were hoping to achieve, as well as any personal details we wanted to share. As a good student, I was happy to follow her directions and thought I would be the first one there, but I was not. Everyone was enthusiastic about getting started. It was interesting to learn that they were not only from higher education, but also from secondary education and from training and development.

Facilitation of Asynchronous Discussions

At the beginning of each module, the e-teacher provided general discussion guidelines, or netiquette rules, which emphasised the importance of participating, contributing, and encouraging. With these guidelines, our discussions were very positive and encouraging. Even when someone in the class was struggling with an issue, many would respond positively to offer advice and encouragement.

The online asynchronous discussions were lively and stimulating, and the teacher was an active participant, sometimes providing answers to questions that were raised, and sometimes raising new stimulating questions. Because the discussions were written and asynchronous (occurring whenever someone felt like submitting a discussion item), they were much more thoughtful than the typical face-to-face discussion. People had time to read another student's thoughts, digest them, and respond thoughtfully. Students also became great resources for the rest of the group. If one person raised a question, often two or three others would respond with answers or online resources. The teacher did not feel obliged to be the only one providing answers. In fact, the teacher was truly a "guide on the side," actively participating and guiding the discussion but encouraging the students to provide the majority of input.

All of the online modules seemed to follow the same pattern in terms of organization, discussions, and assignments, but the quality of the learning experience was really influenced by the tone set by the teacher. Those modules in which the teacher was less involved seemed to be less interesting and less involving for the students. The modules with the greatest interaction and that stimulated more learning were those in which the e-teacher was actively engaged on a daily basis, and showed his or her enthusiasm for the e-learners, the topic, and the discussions through comments that were worded in the most positive way. These modules were so involving that I found myself checking into the course Web site several times a day to see the new postings: at lunchtime in front of my computer and most evenings.

Practical and Relevant Assignments

The assignments for each module were very practical, relating the theoretical readings to the creation of online materials. However, one big difference was that we submitted our assignments to the module Web site so all e-learners in that module could look at the assignments and offer formative comments and suggestions before final submission. The comments were very positive and affirming, and when suggestions were offered it was in the spirit of helpfulness: e-learners helping other e-learners. This was all a part of the process of learning how to provide formative feedback to e-learners, as well as modeling an excellent collaborative process to be used with our own students.

Group Projects

Some of the course projects and assignments were done in groups. It is possible to do group work online if it is well organized and facilitated. One assignment was to create a fictional module Web site around a particular topic. In my small group (members were assigned by the teacher), there was one member in Switzerland, one in New York, one in Texas, and two in California. We decided who would do which piece of the project, and most of our work was done asynchronously through our own group discussion site that the teacher had set up on the course Web site. We also decided to try a synchronous chat just to check in with the group members. Considering the 9-hour time difference between California and Switzerland (and the others in between), we determined a time that would work for all of us. It worked pretty well, but at times it was somewhat confusing because just as I thought of a response to someone's comment, there were three other responses about something else. So, the asynchronous mode generally worked best to pull our project together. We were happy with the course Web site we created as a team, and it was also interesting to see how the other groups developed their course Web sites.

Lessons Learned as an E-Student

From this experience, I learned that e-teaching is completely different from a scheduled lecture or tutorial meeting 3 hours per week. It is much more flexible. As prospective e-teachers, we wanted to know how much time an online module requires of e-teachers. Our e-teachers answered truthfully that the busiest time in online courses is on the weekends because that is when most students have the time to do some concentrated work. So e-teachers plan to be online several times on weekends to respond to questions and problems. In addition, they check in everyday to read student comments and assignments, facilitate discussions, and address questions. If our e-teachers were traveling to a conference, they would often let us know that they would be out of touch for a particular period of time until they had their laptop set up in the hotel room. Because e-learners may also contact the teacher privately through e-mail on the module Web site, the best teachers also felt that it was important to be quick in responding to these individual queries. However, e-teachers usually said that questions that were not of a personal nature should be addressed to the discussion board so that other students may respond, and/or see the teacher's response. There is no question that e-teaching online takes a lot of time and dedication, and a learner-centred approach to e-teacher availability.

As with any learning and teaching method, online learning is not the preferred learning mode for everyone. Some of the people in the online course said that they really missed the face-to-face contact or hearing the voices of the teacher or the other students. Perhaps it is a learning style issue. On the UCLA Web site (and other university Web sites), there is a self-assessment tool for prospective online students to determine how well suited they may be for the e-learning experience. It is important for prospective e-learners to recognize that e-learning also takes much more self-discipline and self-motivation than a face-to-face class. Those who think it will be easier are in for a big surprise. Anyone looking for an easy ride really does not belong in an online programme.

The final module of the UCLA programme was a supervised e-teaching experience with Alfred Rovai, who has written widely on e-teaching practices and was an excellent mentor to us one on one. After receiving the UCLA Certificate in Online Teaching, I was able to immediately apply my learning to create some online self-paced workshops for lecturers interested in learning new teaching strategies. These e-workshops were also designed to provide a test experience as an e-learner, allowing one to see how e-learning works, how it feels, the pitfalls, and the advantages.

WALDEN UNIVERSITY: ORIENTATION FOR NEW FACULTY MENTORS

Background on Walden University

Walden University (http://www.waldenu.edu) is an accredited postgraduate university that started in 1970 based on the learner-centred principles outlined by Harold Hodgkinson, professor at

University of California at Berkeley, in his 1969 article in the journal *Soundings*. The founders of Walden, inspired by Henry David Thoreau, envisioned an institution that would provide the opportunity for adults to earn doctorate degrees as scholar-practitioners so that they might develop into leaders committed to the betterment of society.

Walden University is fully accredited by the Higher Education Commission in the United States, offering master's and doctoral programmes in education, management, nursing, health sciences, psychology, social service, public policy, and engineering. Walden University is based in the United States and has 20,000 online students from 95 countries, including a partnership with the University of Liverpool for three online programmes: the MBA, MS in IT, and MA in information systems management. Walden is part of the large Laureate International Universities network that includes a total of over 240,000 students in 25 universities in 16 countries.

Mentoring Research Students Online

In December 2005, I was invited by Terry O'Banion to join Walden University as a faculty mentor in the College of Education, working part-time at a distance, supervising and mentoring doctoral-level students in the Community College Leadership and Adult Education Leadership programmes. Terry O'Banion is the director of the Community College Leadership programme and was very enthusiastic about Walden University's focus on learning, as outlined in his 1997 book *A Learning College for the 21st Century*. He explained that the doctoral students at Walden must complete three "knowledge area modules" (KAMs) prior to beginning work on their dissertations. In other doctoral programmes in the United States, these might be considered equivalent to the required qualifying exams that are normally completed prior to the dissertation. These KAMs are very lengthy, analysing the breadth, depth, and application of a particular topic relevant to the area of the student's academic work. Each KAM focuses on a different theme: KAM I is Principles of Social Change, KAM II is Principles of Human Development, and KAM III is Principles of Social Systems. Within each KAM, the *breadth* portion is a study of major theorists, the *depth* portion is a study of the current literature that applies the theory to a specific topic, and the *application* portion provides students with the opportunity to apply what has been learned in the *breadth* and *depth* sections through a mini research study or a real-world project aimed at creating a positive social change.

Mandatory Orientation for New Mentors

As a new faculty mentor, I was required to complete a 12-week orientation programme provided by Walden University starting in January 2006. This programme was similar in some ways to the UCLA programme described earlier, with a strong focus on learning theory, facilitation of discussions, and provision of good support to students. However, the major difference in the programme is that we also needed to learn the "Walden way" of KAMs, learning agreements, personal development plans, and the methods for submitting and assessing work. Our online orientation was facilitated by an experienced Walden faculty mentor from the education programme, who had a wealth of experience she was willing to share with us. The group was small with only four of us, but we had well-facilitated discussions around issues of e-teaching and mentoring at Walden University. In order to pass the orientation, we were required to participate in all discussions, complete all assignments and projects (usually one each week), and successfully pass an exam at the end of the orientation course. Those who were unable to complete all of the work were invited to participate in another upcoming orientation, but were not allowed to teach for Walden until successful completion of the full orientation. This fully online orientation was an excellent model for new faculty mentors to experience learning at Walden before starting to teach there.

Lessons Learned from the Walden Orientation Programme

Walden University has a unique structure with its KAMs, and new doctoral students can become very frustrated in the early stages. Without the extensive orientation programme, as a faculty mentor, I would have been equally frustrated. However, by providing a safe environment for new e-teachers to learn about Walden's structures and methods, I was able to provide my early students with the support and advice they needed. Because the programme is fully online for students, it was important for the prospective mentors to gain experience as learners in the same e-learning environment. Of course, some things will be learned only through the experience of working with mentees, but the preparation through the orientation programme provided a firm foundation for us as new mentors.

After examining the best practices in the preparation of e-teachers and two case-study examples of e-teachers prepared through e-learning, it is important to look at the future trends in e-teaching and e-learning.

FUTURE TRENDS

With the rapid growth of e-learning and exponentially growing demand for fully online courses, universities are starting to pay more attention to the need for professional development to prepare e-teachers more effectively. Some universities offer their own professional development programmes in e-teaching, although most are short in duration and few are fully online. It will be important in the future for universities to consider how to best prepare novice e-teachers for effective online teaching and include facilitation and e-moderating to promote deep learning and student success. Will all institutions provide their own fully online e-teaching programmes, or will many academic staff participate in programmes offered by a few institutions that already have excellent programmes in e-teaching? In either case, the need for providing a fully online experience will be met.

CONCLUSION

The purpose of this chapter has been to highlight one important way of supporting academic staff in higher education who are thinking of introducing e-learning as a way of enhancing student learning. This is a critically important part of applied e-learning and e-teaching in higher education. Without good preparation for e-teaching, the quality of e-learning experiences for students will vary widely.

After my two experiences as an e-learner to prepare for e-teaching, I strongly believe in the importance of having a high-quality experience as an e-learner fully at a distance before attempting to be an e-teacher. Universities and colleges that are serious about the quality of their e-learning programmes require their prospective e-teachers to complete a programme or module in online teaching as an e-learner prior to teaching online. If it is not feasible to offer this programme within the institution, it would be worthwhile to support academic staff in participating in high-quality programmes offered by other institutions.

Prospective e-teachers who want to provide a high-quality learning experience for their e-learners should plan to participate in a well-organized, well-facilitated fully online course to see how it feels from the student perspective, whether or not it is required by their own universities. Through this type of immersion in e-learning as professional development, it is likely that the quality of online instruction will continue to improve, resulting in better student e-learning outcomes in the future.

FUTURE RESEARCH DIRECTIONS

Further research must be done in the future to demonstrate the links between e-teacher preparation and student learning and success. Although all research on student success is challenging due to the number of variables that contribute to learning outcomes, it will be necessary to demonstrate the effectiveness of the professional development programmes to prepare e-teachers. Without this evidence, it is difficult to justify a lengthy professional development programme that models best practices in e-learning because these programmes are expensive. This research may also reveal some new ideas for professional development that will enhance e-learning outcomes in the future.

Research in the area of preparation for e-teaching should ideally analyse student learning outcomes, including completion and success rates in e-learning modules and courses. In programmes or courses with high success rates, how are the e-teachers prepared? How many of the e-teachers have participated as e-learners? Literature on e-teaching has often shown, through interviews or surveys of e-teachers, that quite a few felt unprepared when they started e-teaching. It would be interesting to find universities with e-teachers who felt well prepared to determine how many of these e-teachers had an e-learning experience first.

The student perspective is another important area to include in researching this issue. What do students look for in an effective e-teacher? Are the characteristics of e-teachers different in universities that provide preparation for e-teaching through e-learning? How much interaction and involvement in learning do students experience with e-teachers who were e-learners first in comparison to e-teachers who did not have their own e-learning experiences?

Future research in the area of Web-based academic development as preparation for e-teaching must be linked to the literature of academic development, experiential learning, and e-learning. The objective of this research will be to bring together relevant learning theories with e-teaching in order to provide the best possible e-learning experience for our students.

ADDITIONAL READING

The following sources were selected because they focus on the practical aspects of providing professional development for those who are preparing to be e-teachers. They all emphasise the importance of supporting academic staff prior to teaching online. These sources provide details of the ways in which e-teaching is much more than simply putting materials up on a Web site for students. The idea of building learning communities at a distance is a theme that runs through many of these references for further reading.

Chapter 5.23
The Use of Weblogs in Language Education

Thomas Raith
The University of Education Heidelberg, Germany

ABSTRACT

This chapter explores in how far Web 2.0, Weblogs in particular, has changed foreign language learning. It argues that Weblogs, along with Web 2.0, have created new genres for which users need new forms of literacy. A qualitative study on the relationship between the online audience of Web 2.0 and learners' writing processes is presented and the findings are discussed. The study supports the assumption that learners are aware of the social interaction taking place through weblogs and that this awareness of audience influences the writing process. The author's intention is to point out that Web 2.0 has created new communities of language practice and that foreign language learning is happening in these discourse communities through social interaction. The challenge in foreign language education is to integrate these communities of practice into the foreign language classroom.

DOI: 10.4018/978-1-60566-190-2.ch015

INTRODUCTION

From the very beginning, the Internet was a community that offered many possibilities for networking, linking people worldwide and for publishing information for the online community. In recent years the term "social software" has come to describe a new phenomenon within the online world. The social software application that has gained the most attention in recent years are weblogs. Originally, weblogs were mainly created to link together pages on the Web that the weblog author considered interesting or noteworthy. These lists of links included the weblog author's comments on the content of the linked websites. A community of weblog-owners networked around a certain topic, linking and exchanging information. One famous example was the weblog of Stanford college students Filo and Yang, who created a link-catalogue in 1994 that eventually developed into the Internet portal Yahoo! (Möller, 2005).

In the early days of weblogs, the users needed knowledge in programming and had to host blogs on their own servers. Since the introduction of blog-hosters in 1999, weblogs have become more accessible and easier to start for every user on the net: publishing a post on a weblog nowadays is as easy as writing an e-mail. As a result, since 1999 the number of weblogs on the Internet has increased dramatically. In April 2007, Technorati tracked 70 Million weblogs worldwide and estimated that 120,000 new blogs were being created each day ("The State of the Live Web", 2007). Although the numbers only show 15,5 Million active weblogs, the blogosphere is constantly growing. Blogs have challenged traditional journalism through fast and multi-perspective coverage of news which was not possible before. Already by the end of 2004, weblogs were so popular that the Merriam-Webster dictionary chose it as its "Word of the Year for 2004" (Richardson, 2006). Weblogs are only one tool in the growing Web 2.0 family which has changed the way people communicate and network. In how far do these changes affect education and foreign language learning? This chapter discusses this topic in relation to weblogs as Web 2.0 tools. The basic question will be whether weblogs transform learning in the foreign language writing classroom.

WEB 2.0 AND THE TRANSFORMATION OF LANGUAGE LEARNING

O'Reilly (2005) sees, among others, two key features that distinguish Web 2.0 from Web 1.0: the platform-based usage of the Internet and harnessing collective intelligence of Internet users. The Web is the platform on which users work collaboratively and on which they store and exchange data. Rather than installing and using software on the PC, services are used online to create blogs, documents and wikis. These features can be seen as the basic principle of all social software devices which link users for collaboration and social interaction. However, the phenomenon of collaborative projects, like Wikipedia, and the rapid growth of the blogosphere, to name only two, is not only a consequence of new Web 2.0 technology. As Alby (2007) points out, these phenomena go hand in hand with faster Internet connections via broadband and flat rates that are affordable for the masses.

How far, then, has Web 2.0 transformed language learning? Warschauer (2004) describes three stages of CALL which have emerged since the 1970s and have represented the development of technology, on the one hand, and the formation of language acquisition approaches, on the other hand. The first stage, structural CALL, uses drill and practice activities focussing on correct language use. Structural CALL followed an audio-lingual approach to language learning, and the technology was mainframe computers. The 1980s and 1990s were marked by the upcoming communicative approach to language learning. At the same time, the introduction of PCs offered the technology for computer-assisted communicative exercises. The third stage, which Warschauer (2004) calls integrative CALL, has a socio-cognitive approach to language teaching and uses computers for authentic discourse. In this last stage, the computer functions as a tool that connects learners for interaction. In earlier stages of CALL, computers were seen as a tool to support the language learning process. Integrative CALL is different, because it doesn't only use technology to create space for isolated language learning activities, but it uses technology that is made for communication. With Web 2.0 this shift in CALL becomes even more obvious. Communication in the virtual world has become more than simply using a different tool to transfer the same information as with more traditional tools. Web 2.0 has created new genres, new identities, and users need new forms of literacy to interpret information. Therefore, as Warschauer (2004) points out, new teaching methods are required. Shetzer and Warschauer (2000) define electronic literacy as a threefold competence of communication, construction and research. These three aspects are still applicable for Web 2.0 tools, but they are more combined, for example, in blogs, which are simultaneously used for communication, construction and research. Bloggers construct content, are part of a discourse community, and blogs serve as an important source of information.

The approach of multiliteracies, in development by the London Group since 1996, takes the idea of electronic literacy one step further, by including intercultural communicative competence as an essential goal of electronic literacy. This concept sees hypertext as a nonlinear, multimodal environment, where information is "variously coded in animation, symbols, print text, photos, movie clips, or three-dimensional and manoeuvrable graphics" (Luke, 2000, p. 72). These hypertexts are embedded in local cultural diversifications which must be understood by the reader for successful communication. In Web 2.0, which networks people from all over the world, intercultural communicative competence as an integral part of multiliteracies is of great importance. Consequently, foreign language learners must be prepared for these multimodal environments, as speaking the language without understanding the multimodal contexts in which it is embedded, is not sufficient for global communication.

The nationwide longterm-study, JIM, regularly collects data about recreational and media behaviour of young people from 12 to 19 years of age in Germany. In 2007, almost every household in Germany had computer and Internet access, and 67% of teenagers had their own computer; almost every teenager was using computers. The daily use of the Internet increased from 51% in 2004 to 77% in 2007. One third of the participants state that they contribute actively and regularly to some kind of interaction on Web 2.0 (Abfalterer, 2007). These figures emphasize that young people in Germany are already regularly participating in online communication in Web 2.0. These young people are part of global social networking and need corresponding literacy to communicate successfully. Therefore, technology need not assist language learning foremost, but with Web 2.0, technology created new communities in which learners can practice and for which they must be prepared. This requires more than language learning as a linguistic skill, but language learning in the sense of multiliteracies.

THE POTENTIAL OF WEBLOGS FOR THE CLASSROOM

Weblogs are a good example for what is meant by multiliteracies in the context of Web 2.0. Readers of blogs need more than the ability to understand the language in order to really make sense of the content of many blog posts. They also need the skill of understanding the related discourse with other blogs or linked references to truly comprehend the context of the texts. Furthermore, the competence of understanding the writer's cultural context is important. However, many of these aspects are also true for other literary texts — what, then, has changed? The difference is that Web 2.0 is a Read/Write Web, and the reader can easily interact with the writer or can also become an author. Blog readers can write comments or react by posting responses. They become part of a discourse community and interact in a complex multimodal setting. Using weblogs in the language classroom does not simply mean having a nice tool with which to practice writing, but rather is an opportunity to prepare students for communities of practice connected to the use of weblogs or other Web 2.0 tools in real life.

Weblogs have been used in many classrooms in different ways, and a variety of classifications can be found as to how weblogs can help in acquiring a language. Campbell (2003) mentions *tutor blog*, *learner blog*, and the *class blog* as different approaches for using weblogs in the foreign language classroom. Whereas Campbell's classification distinguishes the writers and their purpose for using a weblog, Richardson (2006) analyses the use of weblogs in the classroom in terms of pedagogy. According to Richardson, weblogs are used in schools for a wide range of purposes: a weblog can be put to use as a *class portal,* an *online filing cabinet,* an *e-portfolio,* a *collaborative space,* for *knowledge management and articulation* and as a *school website*.

Richardson points out that one key feature that distinguishes weblogs and the Read/Write Web from more traditional media is that of the potential audience. Here we can see a significant shift compared to traditional media because collaboration with an audience is not bound to the classroom anymore. By means of weblogs, the classroom can be extended to dimensions previously not possible. Ward (2004) points out different benefits of using weblogs in the writing classroom. A genuine audience is one important aspect that can motivate students in the writing process. He quotes Kitzmann (2003), who writes that "the [online] audience is not only anticipated but expected, and thus influences and structures the very manner in which the writer articulates, composes, and distributes the self-document" (p. 1). Thus, the audience encourages writers to present and express themselves.

Furthermore, weblogs not only provide the audience and therefore change the way learners see their products, but they also change the way content is being constructed. Weblogs often belong to a network of writers functioning as a collaborative blog, in which the authors edit each other's texts. Consequently, texts refer and react to other authors, which means that new content is constructed through collaboration. These new ways of constructing content demand of the learners new literacies, as discussed above. Some of the basic criteria of these multiliteracies is that writing is enbedded in an interactive dialogue between the writer and the audience: "The differences between blogging in this manner and writing as we traditionally think of it are clear: Writing stops; blogging continues. Writing is inside; blogging is outside. Writing is monologue; blogging is conversation. Writing is thesis; blogging is synthesis" (Richardson, 2006, p. 31). The contradiction between writing and blogging, which the author points out, might lead one to the conclusion that blogging is not even writing. In the following sections it will be argued that blogging should not be seen as a contradiction to writing, but rather as a certain form of writing, namely writing as social interaction.

Wrede (2003) puts the aspect of discourse in weblogs this way: "[W]eblogs are usually a form of writing in public and with the intention to offer opportunities for communication. A weblog is a constant invitation for conversation – directly and indirectly" (p. 2). In fact, a weblog writer often has a number of different audiences simultaneously: the group of people the writer is collaborating with, the audience the product is presented to, and the wider audience of the Internet. Each audience cannot only just read the text, but write a comment or even an article. Thus, discourse can happen on different levels and can reach a degree of authenticity which would not be achieved without extending the classroom through online networking of that kind.

As we have seen, weblogs can be used in the foreign language classroom for interactive language learning following a sociocultural paradigm. However, the major change weblogs have brought for language teaching goes beyond that. Weblogs have, in company with other Web 2.0 tools, created new genres and new communities of practice which demand new literacies. Therefore, they have not just added some methods to foreign language teaching, but they have transformed the goals by creating new contexts of communication.

TEACHING WRITING WITH WEBLOGS

New communities of practice with new genres demand specific ways of teaching and learning literacies which help the learner to interact in these contexts. With weblogs in particular, new communities of discourse writing have emerged and the question is what kind of approach for teaching writing could support learners in acquiring the respective literacies.

As Hyland (2002) points out, three different approaches to researching and teaching writing can be identified. The first approach can be described to see texts as autonomous objects, referring to structuralism. The focus in this approach is on the correct arrangement of elements, and the idea of language learning is based on "an autonomous mechanism which depends neither on particular writers or readers, but on setting out ideas using correct forms" (Hyland, 2002, p. 6).

The second approach focuses on the writer and the process of creating texts. Learning writing is a process which can be encouraged by providing writers "with the space to make their own meanings through an encouraging, positive, and cooperative environment with minimal interference" (Hyland, 2002, p.23). Since weblogs provide this open space for writer-oriented creativity, they can be used in language learning for such writing processes. However, more traditional media, such as paper journals, can provide this space also, thus it is not this aspect of weblogs which makes them an exclusive and new tool for teaching the writing process.

It is because weblogs fulfill the requirements of the third approach which traditional media cannot easily satisfy, to provide a tool for writing as social interaction, that they can be considered novel and unique. This third model considers that a writer always has a certain purpose and audience in mind when writing a text. Either the audience is directly addressed through the text (e.g. in a letter) or the audience is invoked, meaning that it is meant to read a certain text although it is not addressed directly (e.g. a novel). A text is always about sharing or negotiating meaning with an audience; if there were no audience, there would be no reason to write a text. The writer is influenced by the addressed or invoked audience, which means that there is an interaction between the writer and the reader. Even though this interaction might not be too obvious in many cases, it is an important factor by which the writing process is influenced.

Connected to the notion of audience is the idea of social construction. The writer is a member of a community, and writing is understood as discourse in this certain community. The way we think and communicate is seen as "language constructs generated by knowledge communities and used by them to maintain coherence" (Hyland, 2002, p. 41). Thus, each part of writing happens in a context of a social community, aiming to construct meaning within this community. Writers "position themselves and their ideas in relation to other ideas and texts in their communities and this helps them both to legitimate their membership and establish their individual identities through discourse" (Hyland, 2002, p. 41). This social interaction characterizes the writing processes in weblogs, as described above. The audience for weblog writers is obvious and the blogging community a real, existing community. Therefore, compared to other writing tools traditionally used in class, weblogs have the potential to extend the audience beyond the classroom and to create new writing communities.

Grabe and Kaplan point out that "audience is essential to the creation of text and the generation of meaning" (Grabe & Kaplan, 1996, p. 207). They mention five parameters by which the writer of a text is influenced with regard to the reader: the number of persons who are expected to read the text, the extent to which readers are known or unknown, the difference of status, shared background knowledge and shared knowledge of the topic at hand. Through these aspects, the identity of the discourse community is defined and the patterns of discourse established. It is very likely that, for instance, the discourse between students in a project at university will differ from pupils at a primary school who work on a project. However, within these communities shared patterns of communication help to communicate and negotiate meaning.

Hedge (2000) sees the matter of audience as an important aspect to foster good writing. Real-life audience for her is a precondition for developing real-life writing tasks. In the context of the task-based language learning classroom these real-life writing tasks are of great importance, since they promote meaningful communication.

Teaching writing as interaction in a discourse community can be one way of implementing the sociocultural approach to the foreign language classroom. Swain (2000) mentions that research suggests that comprehensible input alone cannot provide opportunities for language acquisition. Moreover, the role of interaction with its components of input and output in collaborative dialogue constitute language learning.

Lantolf (2000) points out that the central concept of sociocultural theory is the *mediation* of higher forms of mental activity. In second language learning this mediation takes place with others through social interaction, with oneself through private speech, or by means of artefacts like tasks and technology. Sociocultural theorists do not draw a clear distinction between "use" of a second language and "knowledge" of a second language, as in their view use creates knowledge (Ellis, 2003). A central means of mediation is verbal interaction by creating situations in which novices can negotiate meaning and thus participate in their own learning. The expert can function as providing support in order to help the learners reach the next level or understand a certain language structure they need for interaction. This scaffolding is important for reaching the next potential level of development, which Vygotsky (1978) called "the zone of proximal development."

Teaching and learning writing using a sociocultural approach means providing learners with opportunities to engage in collaborative discourse communities with the goal of social interaction. The assumption is that weblogs provide such environments for second or foreign language learners. Moreover, the blogosphere is an authentic community of social interaction through discourse writing. Bonk and King (1998) developed a collaborative writing taxonomy for such electronic writing environments and attempt to describe how electronic writing tools could be used in the context of a sociocultural approach. However, Bonk and King (1998) note that in terms of research, many questions remain unexplored. One of these questions is, "How do different interaction structures and collaboration formats impact student writing?" (Bonk & King, 1998, p. 6). The assumption is that weblogs inherit a purpose for interaction and therefore the impact on student writing should be one that supports connective writing. Some of the findings of the following qualitative study, researching the influence of the online audience on the students' writing process, imply that the collaboration format of weblogs does influence students' writing.

A STUDY ON THE INFLUENCE OF AUDIENCE ON WRITING IN WEBLOGS

Research Design

The study consists of 29 single cases that had the same task to accomplish: writing a reading journal. These single cases were compared to each other with the focus on differences between the writers of weblogs and the ones with paper reading journals. Since different single cases were compared in different sections, the research can be seen as a comparative study (Flick, 2003).

The study explores how an online audience influences students in their writing of a reading journal. The assumption is that a real online audience in the context of a discourse community has certain effects on students' writing. Therefore, in terms of meaningful communication, the outcome of weblog reading journals written for an immediate audience in a discourse community should differ from reading journals written on paper for an abstract audience. The expected outcome of the study was to find out in how far students realize the interactive character of the Web 2.0 and whether this changes their writing in terms of connective writing. The research questions of this study are as follows:

- To what extent do weblogs support meaningful writing?
- What differences are there in students' writing between weblogs and paper journals?
- To what extent does the online audience of a discourse community influence students in their writing of a reading journal?

The participants consisted of 29 students of a grade 9 secondary girl's school in Germany who had English as a foreign language in their fifth year. According to the Common European Framework the goal set by the state curriculum for this grade is to reach level A2 which means they should be basic users of English as a foreign language on a way stage level (Council of Europe, 2001). The test scores on a class level showed that most students met the criteria of A2, some students are slightly beneath A2 and few even scored B1 (independent user on a threshold level). The students could choose whether they wanted to write a paper journal or create a weblog on the Internet. 10 students decided to write a weblog and 19 students wrote a paper journal. It was for the first time that the students did a reading journal. None of the students had worked with a weblog before.

The participants were assigned the task of writing a reading journal about the book *If You Come Softly* by Jaqueline Woodson. The reading process was supported in class with pre- while- and post-reading tasks. They were instructed to write their thoughts and impressions about the chapters they had read by using texts, photos, drawings, articles or poems. Each student had to write at least one post about each chapter during a period of six weeks. The students could choose what they wanted to write about and how they wanted to comment on issues they considered relevant. The blogging software used for the project was developer-hosted blogs on blogger.com. The advantage of blogger.com is that creating a blog is easy and free, without downloading software and hosting by the user. Furthermore, password protected communities can be established. But there are other providers offering similar features, like wordpress.com.

DATA COLLECTION AND ANALYSIS

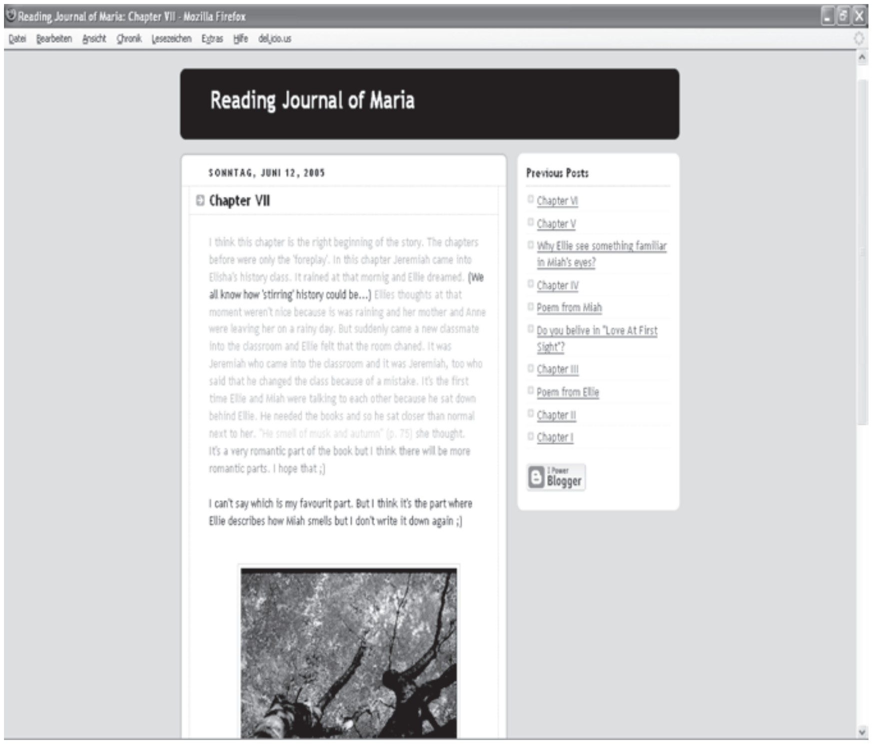
The data consisted of the students' reading journals (weblogs and on paper), two questionnaires, and a guided interview. The first questionnaire was done before the students started to write their reading journals; the second questionnaire and subsequent interviews, after they had finished their journals. The data was analysed using Glaser's (1998) grounded theory.

First Questionnaire

In the first questionnaire the type of questions was mostly open, following the qualitative paradigm. In response to the question regarding the students' underlying motivation for choosing either a weblog on the one hand or a pen-and-paper journal on the other, three different categories emerged: (a) Personal preferences, (b) Computer Issues and (c) Audience.

Category (a) summarizes students' general statement, e.g. "I decided to work with a weblog because I have never done it before." Categories (b) and (c) stand for two single topics that appeared in most answers. Either students saw their decisions in the context of computer issues (e.g. "I decided not to work with a weblog because we don't have Internet access at home") or in the context of the audience connected to weblogs (e.g. "I didn't choose weblogs because I don't want to publish anything" or "I chose the weblog because I like the idea that everyone could read my texts"). Of

Figure 1. Screenshot of a student's weblog



particular interest for the research project is category (c), because it reveals that many students were aware of the potential online audience, regardless of whether they considered the audience as motivating or threatening. Another remarkable fact is that in the answers none of the students associated pen and paper journals with an audience. In general, the findings of the first questionnaire suggest that the students had a general awareness of audience that they associated with weblogs but not with paper journals.

Reading Journals

The data analysis of the reading journals referred to the first research question. The main concern when analysing the data of the reading journal was to identify any differences between the texts written in weblogs and the ones written on paper. Through the open coding process, following the *grounded theory*, the reading journal texts were analysed to find distinctive features. The findings suggest that in general the students' texts can be classified in three different categories:

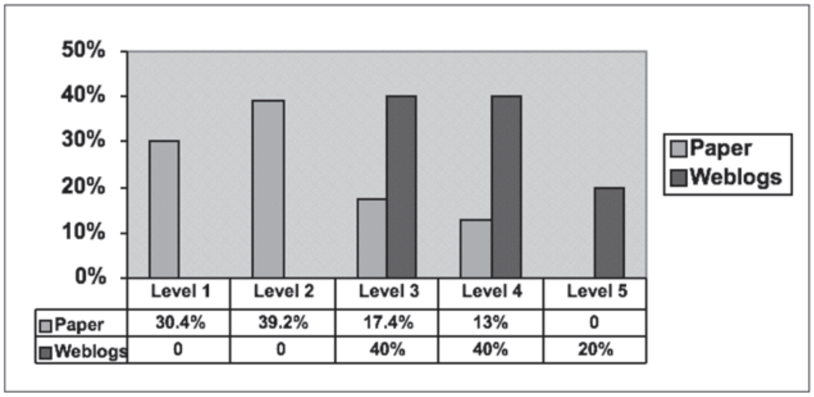
Category 1: Summaries of the Chapters

This category represents students who only wrote summaries of each chapter. The main goal of the writer is to summarize the most important things that happened in the story or the respective chapter.

Category 2: Summaries of the Chapters with Added Opinion

This category represents students who wrote summaries of each chapter and added their personal opinion to the summary. The main goal of the writer is to summarize the most important things that happened and then to add the personal opinion. The amount of text devoted to the expression

Figure 2. Findings of reading journal analysis



of personal opinion is in relation to the amount devoted to summaries much smaller.

Category 3: Personal Comment with Summary Included

Students who wrote personal comments on each chapter fall into this category. These comments consist of utterances of personal opinion and feelings. They can contain summaries of the chapters as well, but in the light of the personal perception of the writer.

Using the above categories, the data was analysed a second time with the intention of developing a concept which could help describe the distinctive features in a more detailed way. In particular, the issue of writing from a personal perspective versus writing summaries should be at the centre of the analysis. For that purpose descriptors were developed which describe the differences between the students' reading journals more precisely.

In the last phase of the coding process each reading journal was classified into one of the described levels. Figure 2 summarizes the findings.

The numbers show the percentage of each comparison group for every level. The findings show that the difference between paper journal students and weblog students is significant. The students with weblogs all reached at least levels 3 to 5. On the other hand, only 30 percent of the students with paper reading journals reached these levels. Additionally, none of the paper reading journal students reached level 5 and only 13 percent reached level 4. However, 60 percent of the students with weblogs were in levels 4 and 5.

For clarification, it has to be added that these figures do not indicate anything about the accuracy of the students' texts. Nevertheless, the summaries show clearly identifiable trends with regard to content; students who wrote weblogs expressed to a much higher degree their own opinion, attitudes and personal thoughts, as defined in the descriptor. The language of the "weblog students" was not necessarily better in terms of language accuracy. However, it was more personal than the language of the students with paper journals. One can say that the students with weblogs talked more about themselves, they wanted to communicate a message. To find out why they wanted to communicate on a more personal level, we will have to look at the data collected in the second questionnaire and the interviews.

Second Questionnaire

The students completed the second questionnaire after they had written their reading journals. They

Table 1. Levels of student interaction

Level 1	Writes only short summaries of the readings. No personal reflections or expression of attitudes, no utterance of opinion. Example: Selina (paper journal): Chapter 10 Jeremiah remembers his childhood and his father's new girlfriend Lois Ann. It makes him sad, especially that her parents could hurt each other. Jeremiah is thinking about Ellie, he showed his feelings. And he thinks about his life and it makes him sad, because so much happened.
Level 2	Writes mainly summaries of the readings with some personal reflections. In relation to the summaries the personal reflections is very brief and lacks expression of attitudes. Personal opinion is expressed, but only in short, isolated sentences. Example: Theresa (paper journal): Chapter 10 Loneliness is in the air. Jeremiah is sitting in his mother's room looking at pictures of her and his Dad. Thinking about how it was in the past when the family was still together. Now his parents are separated, because his dad left them. He went to another woman. Lois Ann. If my parents were separated a world would crash down for me. Jeremiah is also thinking about Ellie. He's thinking about going to kiss her. Soon. It's sweet to read this, but how does he know if Ellie likes kissing him? I think he'll find out …
Level 3	Writes summaries of the readings and personal reflections. The amount of personal utterances is significant but still less than the summaries. Attitudes and personal opinion are mentioned frequently and sometimes in detail. Example: Lisa B. (paper journal): Chapter 10 This chapter is about Jeremiah. Jeremiah explains how he felt when he saw his dad with his new wife Lois Ann. He always saw the picture from his mother when she married his father. He thought back at the marriage and that his parents thought their love will be forever. Jeremiah said that he sometimes want a brother or a sister. He also thought about Elisha and her smile. Jeremiah looked at the house and noticed how empty it was and that the house echoed when he was speaking. I know that it is hard when your dad or mama had an new wife or husband but you must except it whatever happens, but not every person will except it because it's hard. I think Jeremiah is in this situation but I also think he except it, because he loves his daddy deep in his heart what ever happens.
Level 4	The amount of summary compared to the amount of personal reflections is about equal. Attitudes and personal thoughts are expressed frequently and in detail. Personal opinion is expressed by developing arguments consisting of several sentences. Alena (weblog): Chapter 10 This Chapter is very hard. There are a lots of feelings I can't really discribe just understand. Jeremiah is in his mothers room, there are photos and he look at them. There are old photos but the most important photo is the picture with his mum in a wedding dress. He cry, he imagine whats happend wrong. What happend when he was little and can't understand. A long time ago the father left his mum but Jeremiah couldn't understand he was just 12 or 13, he smiled because he couldn't understand that it will be a hard time. But now he understand all what's happened. I think he hate Ann Lois, I think he hate his father too. But did Jeremiah hate him really? I think he want to hate him but he can't, he left his mother but not himself. There is a thing, a little thing which nobody see. On the next day his parents would be 17 years married. I think he tought at this and how it could be when his parents where together now. I think when two people separate each other, they haven't got a future because when the love goes the love can't come again. Jeremiah dream, he dream that his parents will be together one day, without Ann Lois. But maybe there is a light:) I call the light Ellie, maybe she can show him the way in the happyness. I think he love Ellie really, he has longing at her because he want to tell her all what's happened and makes him sad.

were asked about their experiences with writing the journals and in particular their motivation and what kind of audience they had in mind while writing.

The analysis of the second questionnaire reveals, among other things, two important categories related to the relationship between the writing process and the potential audience.

The first category (A) refers to the kind of audience writers had in mind, whereas the second category (B) is concerned with the influence the audience had on the writers. Each category has been divided into three subcategories that can be described as follows. A table displaying the students' answers and a brief analysis of the answers follows the description of each category.

Table 1. Levels of student interaction

Level 5	The amount of summary compared to the amount of personal reflections is at least equal. The summaries are written in the context of a personal perspective. Attitudes and personal opinion are expressed frequently and in detail. The personal opinion is expressed by developing arguments including several sentences. Maria (weblog): Chapter 10 It's a very sad chapter and I … I don't know … I was shocked. I stared for a few minutes at the last word and thought nothing. I still don't know what I should think. Oh yes … I should describe what made me so shocked. It was because of Jeremiah. He was in his mother's room and looked at the pictures wich stood on her dresser. There was a picture from his mother in a wedding dress and she smiled and looked happy. Very happy. When he looked at this picture he thought about the relationship between his mom and his dad. They were nearly seventeen years undivorced. It was a long time but they only had one child – Jeremiah. He felt very lonely but he wouldn't like a sister or a brother. "He wanted more than that – somone deep. Somebody who could know him -know all of him- the crazy things he dreamed on stormy nights, when he woke with tears in his eyes and pulled the covers tight around him" (p. 100). Then he thought about Ellie. Ellie was there in his head and didn't go away. I think they need each other. Both need someone who's there for the other person and who knows all about the other person. And if it's only for a short time. (now I think so because the book isn't very long and we are at chapter X already and not much happened. Oh … I deviate from the description. Yes. He thought about Ellie and how much he needs her. It was a depressing situation: the empty house, his oppressive situation with his mom and his dad, his pain about all the discrimination. It was too much and at the end he cried. The sweet part in this chapter: "I'm going to kiss you soon, Jeremiah had found himself thinking. I don't know when or where or how, but soon I'm going to kiss you" (p. 101). I love this part because it's so sweet and…I don't know an other word for this sentence. But I liked the part that I put in my thoughts (the other blue sentence), too.

Category A (Kind of audience)

- **A1 The teacher:** Students who mentioned that they were aware of the teacher as audience.
- **A2 The teacher, fellow students and friends:** Students who mentioned that they were aware of the teacher, fellow students and friends as potential readers.
- **A3 The online community:** Students who mentioned that they were aware of the online community as potential readers.

The figures in Table 2 show a clear difference between the students who wrote paper journals and those with weblogs. The ones who wrote paper journals had either only the teacher, or the teacher and classmates, or friends in mind while writing. The students with weblogs were up to 90% aware of the audience in the online community. Although the weblog students knew that the teacher would read their blogs, none of them mentioned the teacher as reader. This implies that the students associated weblogs strongly with the online community connected to them.

Table 2. Findings category A

Audience Category	Total	Paper Journal		Weblog	
Category A1	8	8	44,4%	0	0,0%
Category A2	11	10	55,6%	1	10,0%
Category A3	9	0	0,0%	9	90,0%

Table 3. Findings category B

Influence Category	Total	Paper Journal		Weblog	
Category B1	14	12	66,7%	2	20,0%
Category B2	11	6	33,3%	5	50,0%
Category B3	3	0	0,0%	3	30,0%

Category B (Influence of Audience)

- **Category B1: No Influence, no comment.** Students who made it clear that they think the audience they had in mind did not influence their writing at all. Students who didn't make any comment are included as well.
- **Category B2: Making it interesting and understandable.** Students who mentioned that they tried to write accurately, so that others will be able to understand their texts. Furthermore, many said in the same context they wanted to make the texts interesting, because they had in mind that someone would read the texts.
- **Category B3: Writing personally.** Students who answered that they tried to write on a personal level. Some mentioned that this was meant to express attitudes, others wrote that they wanted to tell their opinion.

Table 3 indicates a tendency towards a greater influence of the audience on writers of weblogs than writers of paper journals. 66,7% of the students with paper journals either negated the influence of audience on their writing or did not mention any influence (category B1), while only 20% of the weblog writers were classified in this category. In category 2, more weblog writers (50%) than paper journal writers (33,3%) mentioned that, because of the audience, they wanted to make the journal more interesting or understandable. In category 3 the difference is even clearer. 30% of the weblog writers think that the audience makes them write more personally, but none of the paper journal writers.

To summarize the analysis, we can say that 80% of the weblog writers see an influence of the audience on their writing, but only 33,3% of the paper journal writers can see any influence of the audience on their writing process.

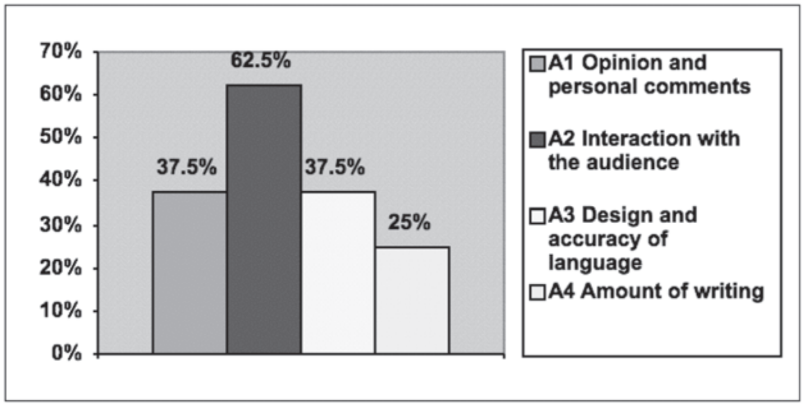
Guided Interviews

In the guided interviews the students were confronted with, amongst others, the observation that the weblog students wrote more personal comments and showed a higher degree of reflective writing. The students were asked to comment on these findings and come up with reasons for the differences. The open coding process was done separately for each comparison group. Therefore, the categories for the weblog students and the paper journal students are different.

Students with Weblogs (Category A)

- **Category A1: Opinion and personal reflections.** Because they knew that other people would read their weblogs, they wrote more about their opinion and showed personal reflections. These were typical answers of students who can be categorized in category A1. They said they wanted to make their weblog personal and make the reader understand what they think about certain parts of the book.
- **Category A2: Interaction with the audience.** Category A2 is in a way similar to category A1 with regard to personal communication. However, it focuses on answers in which students talk about interaction with the audience. This possibility of communicating and interacting with the audience caused them to write in a personal manner and to negotiate meaning.
- **Category A3: Design and accuracy of language.** Some students described how their consciousness of audience motivated them to pay more attention to form, i.e. either to formally correct language and/or to the appearance of the weblogs themselves. The two aspects are put together, since they both deal with form rather than with content.
- **Category A4: Amount of writing.** In addition to other influences that the weblog

Figure 3. Findings guided interviews weblogs



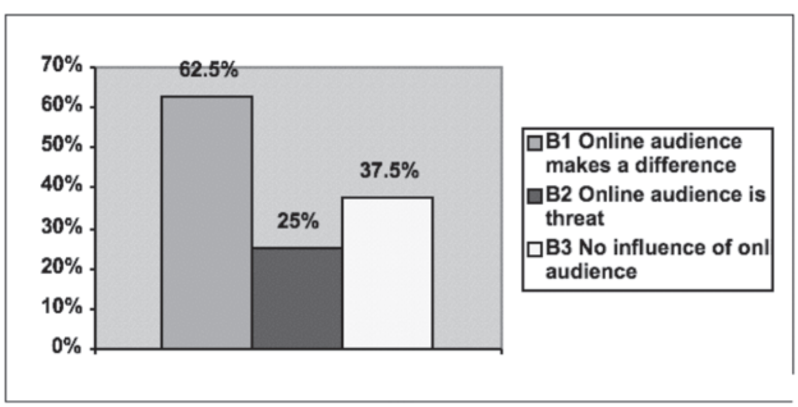
authors' awareness of the audience had on their weblogs, the weblog authors also tended to produce a larger amount of text. Answers in this category implied that the students thought they wrote more because they were aware of the fact that someone was actually going to be reading their weblogs.

The findings of the interviews with weblog students (Figure 3) indicate that most students in this comparison group had an awareness of the online audience and were convinced that these potential readers influenced their style of writing. Moreover, 62,5% mentioned that they meant to interact with the audience when writing posts.

Students with Paper Journals (Category B)

- **Category B1: Online audience makes a difference.** Although they did not experience an online audience for themselves when writing a reading journal, these students mentioned in the interviews that they think an online audience makes a difference concerning the content of writing. They based this assumption on observations they made on the weblogs of their classmates.

Figure 4. Findings guided interviews paper journals



- **Category B2: Online audience is a threat.** Some students see the online audience as a threat. They did not want anybody to read their texts; therefore, they didn't use weblogs themselves. Although most of them did not specify reasons for that fear, they would feel uncomfortable with an online audience in mind.
- **Category B3: No influence of online audience.** Category B3 is comprised of students who mentioned that they don't see an influence of the online community on the writing process. They asserted that there is no difference between weblogs and paper journals with regard to audience influence.

Figure 4 shows that 62.5% of the interviewed students with paper journals think an online audience influences content, although they did not experience an online audience themselves. 25% of the interviewed students with paper journals perceived the online audience as a threat. 37.5% of the paper journal students found the online audience had no influence on the writing process. One of the most interesting findings of the guided interviews is the fact that a majority of the paper journal students saw the online audience as a main reason for more reflective and personal writing. These findings confirm the shared notion of the weblog students, the majority of whom showed at least some cognizance of an online audience.

CONCLUSIONS FROM THE STUDY

Awareness of Audience

In summary, we can say that the data show that the students' writing process reflects an awareness of the online audience. Both, weblog writers and paper journal writers mentioned the online audience as an influence either on the decision-making process for or against weblogs, or they saw that the online audience influenced the writing process of the weblog students. This shows that the audience, as is typical for social software applications like weblogs, is something that students are acutely conscious of in the writing process. They are aware of the audience and it influences them in their writing process. Thus, we can speak of a real and immediate audience since it was not constructed or made up by the teacher or through an artificial textbook task ("Imagine you are writing a letter to a friend"). Moreover, it exists independently of the task put to the students. They were not told to imagine an audience or someone who would read their entries: they were automatically aware of the audience by virtue of their familiarity with the weblog medium. These findings support the idea that students associate weblogs directly with an audience as Richardson (2006) and others have pointed out.

Meaningful Communication

Before having a look at the data here, clarification of the term "meaningful communication" is in order. For this purpose, Littlewood's (2000) definition can be helpful. He describes a continuum from non-communicative learning to authentic communication with three categories (pre-communicative language practice, communicative language practice, structured communication) in between. The closer an activity moves towards authentic communication, the more a focus on meaning can be identified. He defines authentic communication as "Using language to communicate in situations where the meanings are unpredictable, e.g. in creative role-play, more complex problem-solving and discussion" (Littlewood, 2000, p. 5).

Which findings here can be associated with this definition of meaningful communication? In this respect, the findings of the reading journal are of interest. Students who wrote weblogs expressed their personal opinions and attitudes to a considerably higher degree than those students writing paper journals. These findings show that students with weblogs shared their opinion and personal attitudes on the book to a greater extent than paper journal students. Since sharing opinion and personal attitudes means communication and negotiation of meaning, students with a higher degree of these characteristics of writing can be classified in Littlewood's categories on a level close to "authentic communication." On the other hand, students who wrote mostly summaries of the chapters just followed a rather pre-communicative language practice, because they did not try to negotiate meaning or to communicate a message, they simply reproduced content. Since students with paper journals could be classified to a much higher level than weblog students into the category of "mostly summary writing," they do not fulfil the criteria of authentic communication to the same degree as weblog students do. The students themselves assumed that the difference is rooted in the online audience that is associated with weblogs. These results support the assumption that weblogs are a new text genre, one of connective writing, by which author and audience communicate with each other.

Community Discourse

Hyland (2002) along with Grabe and Kaplan (1996) see a "discourse community" as an essential aspect of authentic writing. Authentic writing always happens in the context of a social community, aiming to construct meaning within this community. The findings of the research here indicate an awareness of such a social community. The weblog writers' awareness of audience and the higher level of focus on meaning of the weblog students' writing compared to the paper journal students' writing suggest that the weblog students saw themselves as part of a social community in which they wanted to negotiate meaning. In particular in the interviews most weblog students mentioned that they intended to interact with the audience. Hence, they saw themselves as part of a discourse community. We can say that weblog students show a high awareness of a social community they want to interact with.

FUTURE TRENDS

Interaction and collaboration in Web 2.0 are becoming increasingly important in a globalized world and a new kind of social networking through weblogs is one key feature of this change. Users who want to participate in these social networks need the skills to understand multimodal texts. The concept of *multiliteracies*, which combines intercultural communicative competence with electronic literacy, helps to describe the skills learners of a foreign language will need to reach that goal. In the light of these changes, a sociocultural approach in the foreign language classroom will gain greater importance. For the use of weblogs in foreign language education this means that *networking* and interaction can happen within a class or beyond the classroom in collaboration with other classes worldwide. In tele-collaborative projects weblogs can be used for publishing texts, exchanging ideas and perspectives on certain topics, or in a literature project. The sociocultural dimension of language acquisition is a vital characteristic of such projects. However, even though weblogs have the inherent potential to facilitate the kind of interaction that supports the language learning process, this process doesn't automatically come about simply by using the medium. It is important also to consider the aspect of content: if students have nothing to say, it doesn't matter in which medium they have nothing to say. Learners need meaningful, authentic tasks that encourage them to produce meaningful, authentic output. Nunan (2004) points out that the classroom itself always has a pedagogical dimension, but that the goal of task-based language learning is to prepare learners for real-world tasks. Therefore, the basic question is what learners need to do with language and how we can prepare them for these situations.

As Van den Branden (2006) says, "Tasks are supposed to elicit the kinds of communicative behaviour (such as the negotiation of meaning) that naturally arises from performing real-life language tasks, because they are believed to foster language acquisition" (p. 9). Further research has to be undertaken to explore what kind of tasks support social interaction with weblogs and how the students' development of *multiliteracies* can be encouraged by certain settings.

CONCLUSION

As this chapter has shown, Web 2.0 has created new dimensions of communication. Some key aspects of this transformation are social networking, interactive user-generated content and global collaboration. This change has led to new communities in Web 2.0 and new kinds of genres are developing. This in turn requires a different literacy of the learner. Weblogs, for example, represent different text modes: creating user-generated content, interaction between the author and readers, discourse between different authors and information on a certain topic. Furthermore, weblogs are contextualized in a certain cultural setting which the reader needs to be aware of to understand the implication of texts. These different modes require *multiliteracies*. The study has shown that students were aware of the discourse community connected to weblogs. Their texts showed a higher amount of connective writing, meaning they had an audience in mind to interact with. This supports the assumption that weblogs have created a new genre and that users are aware of the multimodal levels connected to blogging. In summary we can say that Web 2.0 has transformed writing, in particular writing in weblogs. Moreover, Web 2.0 has changed language learning because speakers of a foreign language already use Web 2.0 to communicate meaning and generate content in new genres, by using the foreign language as a lingua franca. Therefore, the community of language practice is already existent. The challenge of foreign language education will be in how far teachers realize these changes and prepare learners for these new environments of language practice. There is a variety of possibilities to work with weblogs in foreign language education and create opportunities for authentic language practice.

KEY TERMS AND DEFINITIONS

Blogosphere: The term relates to the perceived network that joins all weblogs on the Internet together in one community.

Collective Intelligence: A form of intelligence that emerges from a community of individuals who collaborate together. It is an approach to working on products such as texts, documents, codes, decisions with no centralized hierarchy. One central idea is that the collective product of a community is more than just the sum of the individual parts.

Community of Practice (CoP): A group of individuals who engage in and contribute to the practices of their communities through active participation and therefore share a common identity. The term *community of practice* was created by Etienne Wenger and Jean Lave in 1991, who positioned learning in the context of social interaction. One substantial part of knowledge acquisition in *communities of practice* is the construction of knowledge through participation in a community.

Discourse Community: This term connects the notion of discourse (typically relating to numerous forms of communication) with a group of users, usually on a specific subject or area of interest. A discourse community might be used to describe a particular group where members meet to discuss topics of specific interest to them.

Electronic Literacy: The ability to read and write in an electronic medium and to find, organize and make use of information in the context of a hypertext environment. Electronic literacy combines texts and other media, has a focus on collaboration and includes the use of online sources.

Multiliteracies: The term deals with the complexity of language in two major aspects: first, the multimodality of texts through the increasing importance of the written word as part of visual, audio and spatial patterns, and second the cultural and linguistic diversity through global connectedness.

Sociocultural Approach to Language Learning: This approach derives from sociocultural theory that sees learning as the mediation of higher forms of mental activity through interaction. A central means of mediation is verbal interaction by creating situations in which novices can negotiate meaning and thus participate in their own learning. The expert can function by providing support in order to help the learners reach the next level or understand a certain language structure they need for interaction.

Chapter 5.24
The Effects of Web-Enabled Self-Regulated Learning and Problem-Based Learning with Initiation on Students' Computing Skills

Pei-Di Shen
Ming Chuan University, Taiwan

ABSTRACT

Vocational degree earners represent a major portion of the work force in Taiwan. However, the reality of computing education in Taiwan's vocational schools is that it's not so practically oriented, revealing much room for improvement. In this context, we conducted a quasi-experiment to examine the effects of applying web-based self-regulated learning, web-based problem-based learning with initiation, and their combination to enhance students' computing skills. Four classes in successive years, with a total of 177 third-year students, were divided into 2 (SRL vs. non-SRL) × 2 (PBL with initiation vs. PBL without initiation) experimental groups. Results were generally positive. Results revealed that the effects of web-enabled SRL, web-enabled PBL with initiation, and their combinations on students' computing skills have significant differences. We hope that the online teaching method applied in this study is also useful for those teachers engaged in e-learning, specifically, in vocational schools. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

The vocational education system in Taiwan constantly evolves to meet needs such as: the new demands for highly skilled manpower, continued progress of modern technology, worldwide economic development, changing industrial structure, and social/cultural changes. However, vocational education in Taiwan is highly competitive in that it must attract sufficient student enrollment in the face of continually decreasing birth rate and rapidly increasing number of schools. Students' technical skills and the number of professional certifications earned are the main criteria when judging teachers' teaching performance and students' learning effects. However, students in these schools tend to have lower levels of academic achievement. They have low interest and negative attitude toward their learning (Chen & Tien, 2005), spend more time on part-time jobs, do not adequately get involved in their schoolwork, and don't care so much about their grades (Shen, Lee, & Tsai, 2007a). Teaching in such a context, particularly teaching courses in application software – with the target on earning certificates – is a great challenge to most educators.

Web-based instruction seems to be an ideal learning environment because students can access an almost unlimited amount of information and apply it in multiple ways (Kauffman, 2004). However, implementing e-learning for students with low self-regulatory skills inevitably runs high risks. It is a big challenge for teachers to help college students, who are often addicted to the Internet, engage in an online course in an environment with filled with millions of interesting websites, free online games, and online messenger. This addiction to the Internet and the lack of on-the-spot teacher monitoring in web-based instruction makes it even more difficult for students to concentrate on online learning. Moreover, teachers generally feel that students' lack of time management skills is the greatest problem and obstacle to learning in virtual environments. However, the students do not perceive lack of time management as a problem (Löfström & Nevgi, 2007). In this context, it is very important to develop students' skills of self-regulated learning (SRL) to manage their learning in web-based learning environments (Winnips, 2000). Therefore, SRL was applied in this study to help students develop regular learning habits.

Courses in application software traditionally emphasize memorization by applying short, disjointed, lack-of-context examples. Even the professors in National Open University in Taiwan who teach on-the-job students Microsoft Office through television also tend to use short, inappropriate examples in their curricula. The lack-of-context examples in textbooks and used by lecturers may result in uncompetitive employees. There is a gap between what is learned in school and what is required in the workplace (Wu, 2000). In this regard, the computing education in vocational schools in Taiwan can hardly be deemed as effective. In order to increase students' learning motivation and to develop practical skills, problem-based learning (PBL) is considered to be one of the most appropriate solutions. PBL uses real-world, simulated, contextualized problems of practice to motivate, focus and initiate content learning and skill development (Boud & Feletti, 1991; Bruer, 1993; Williams, 1993). It is believed that PBL would help less academically inclined students to develop practical computing skills.

However, students with low academic achievement usually lack the ability to seek essential information and solve the problems they face, particularly in a web-based course without the teacher's on-the-spot assistance and monitoring. Thus, in a PBL environment, these students have to climb a stiff learning curve and overcome much resistance that might pose challenges to both instructors and students, particularly in the initial stage. This stiff learning curve may become a bottleneck and limit the potential effects of PBL. In this regard, we believe that a teacher should provide assistance to his/her students as they adapt to PBL. For example, establishing students' background knowledge and developing required skills is especially important before asking students to solve simulated problems. This could help students be more confident and more involved in the PBL environment and expand the effects of PBL.

As more and more institutions of higher education provide online courses, the question arises whether they can be as effective as those offered in the traditional classroom format (Shelley, Swartz & Cole, 2007). However, few studies have discussed effective online instructional methods for vocational students (Shen, Lee, & Tsai, 2007a). Moreover, there has been relatively little empirical research on students' SRL with such complex technology-based learning environments (Azevedo & Cromley, 2004). Appropriate contextualization is decisive in making educational software and teaching websites effective; otherwise, the potential of even the best program will remain largely unexploited (Bottino & Robotti, 2007). Therefore, we redesigned a course that focuses on the development of students' skills of web page programming and website planning to integrate innovative teaching methods and learning technologies to help students learn. In this study, we conducted a series of quasi-experiments to examine the effects of web-enabled SRL, PBL with initiation, and their combinations on vocational students' skills in using application software.

SELF-REGULATED LEARNING

Zimmerman and Schunk (1989) define SRL in terms of self-generated thoughts, feelings, and actions, which are systematically oriented towards attainment of students' own goals. SRL is also defined as a learner's intentional efforts to manage and direct complex learning activities and is composed of three primary components, namely: cognitive strategy use, meta-cognitive processing, and motivational beliefs (Kauffman, 2004). In a SRL environment, students take charge of their own learning by choosing and setting goals, using individual strategies in order to monitor, regulate and control the different aspects influencing the learning process and evaluating their actions. Eventually, they become less dependent on others and on the contextual features in a learning situation (Järvelä, Näykki, Laru, & Luokkanen, 2007). Characteristics attributed to self-regulated persons coincide with those attributed to high-performance, high-capacity students, as opposed to those with low performance (or learning disabilities), who show a deficit in these variables (Reyero & Tourón, 2003; Roces & González Torres, 1998; Zimmerman, 1998).

As for the effects of SRL on using computer software, Bielaczyc, Pirolli and Brown (1995) incorporate self-explanation and self-regulation strategies in the attainment of the cognitive skill of computer programming. They find that their treatment group, which incorporates the self-regulation strategies of self-monitoring and clarifying comprehension failures in conjunction with self-explanation strategies outperform a control group that did not have the benefit of instruction in these strategies. Their study implies that in addition to knowledge acquisition strategies, students benefit from the incorporation of strategies which allow them to plan, monitor, and evaluate their understanding and strategy use (Bielaczyc, Pirolli & Brown, 1995). In a similar vein, this study provides us an insight that SRL is appropriate to be applied in computer software education.

Previous studies have established that self-regulation skills can help foster learning from any instructional method (see Ertmer, Newby, & MacDougall, 1996; Lindner & Harris, 1993; Weinstein, 1989; Zimmerman, 1990). With regard to the effects of SRL in the online learning environment, it is indicated that successful students in an online course generally used self-regulated learning strategies and the effect of self-regulation on students' success was statistically significant (Yukselturk & Bulut, 2007). In Shen, Lee, and Tsai's (2007b) study, it is also revealed that the intervention of web-enabled SRL contributes to students' learning.

However, only a few psychological studies investigated the research questions of how learners should be supported when learning to use a software product and how instructions should be designed to achieve effective software training. Various fields of researchers should make contributions to this topic, which will not only allow for the formulation of recommendations and guidelines for instructional approaches to software training, but also provide valuable knowledge concerning theoretical and educational issues beyond software training (Bannert & Reimann, 2000). Therefore, the authors not only explore the potential effects of web-enabled SRL on students' computing skills, but also provide an instructional design for web-enabled SRL in this study.

PROBLEM-BASED LEARNING WITH INITIATION

Problem-based learning is a teaching method that may engage students in authentic learning activities by using challenging problems in practice as a starting point, stimulus, and focus for learning (Barrows, 1985, 1986). PBL may help students achieve learning goals such as professional reasoning, integration of scientific, academic and professional knowledge, and lifelong learning skills (Dunlap, 2005). Many researchers have reported PBL's positive impact on knowledge and skill acquisition and transfer, problem solving, attitudes and opinions about courses and programs, measures of performance, and self-directed learning (Albanese & Mitchell, 1993; Berkson, 1993; Colliver, 2000; Davies, 2000; Norman & Schmidt, 1992; Vernon & Blake, 1993).

PBL is a flexible approach, demonstrated to work well with both small teams and large groups. However, there might be disagreement whether PBL will be as effective or even possible for online learning. In this regard, Chanlin and Chan (2004) examined the effects of PBL in a web-based approach. Results revealed that students in the PBL treatment group perform better than those from the control group. Furthermore, in Shen, Lee, and Tsai's (2007a) study, it is indicated that the intervention of web-enabled PBL contributes to students' development of computing skills. However, low-academic-achievement students usually lack the ability to seek the essential information and solve the problems they face.

Technological problem-solving skills provide students with the opportunity and facility to fulfill the various requirements of the technological design process, regardless of learning environment type. For example, students participating in web page programming lessons initially require some form of teacher exposition of the necessary skills to enhance their competent use of Microsoft FrontPage software. Once understood and learned, this knowledge serves to support student-initiated design and problem-solving activities within the same web page programming learning environment. Similarly, more traditional teaching supports students' procedural abilities, in terms of hand and machine skills, until students are adept at applying these previously acquired skills during their technological design activities (Walmsley, 2003). Technology teachers need to facilitate with students the autonomous development of their own cognitive and metacognitive strategies when solving technological problems. It is argued that these types of learning environments require a teacher-facilitated student-centered pedagogy (Deluca, 1992; Johnson, 1996). Therefore, it is believed that the effects of web-enabled PBL with initiation on students' skills with application software are positive, and higher than those without.

METHODS

Participants

The participants in this study were 177 vocational students during a period of two semester from four class sections each taking a compulsory course titled 'Web Page Programming and Website Planning' in a university of science and technology in Taiwan. None of them majors in information or computer technology. Students at this university were expected to spend much more time and effort in mastering a variety of technological skills as compared to those in comprehensive universities in Taiwan.

Course Setting

The course under study is a semester-long, 2 credit-hour class, targeted at third-year college students in the department of business administration. This course focuses on the development of students' skills of web page programming and website planning. Computing education is emphasized for students of all levels and disciplines. Even students in the department of business administration or nursing still have to develop the required computing skills.

Students in this online course have to solve a series of tasks by applying several application software packages, including the tools of website building, web page programming, graphic design, and file transfer software. They are required to collaborate to build up business-quality websites. Therefore, there will be real products, that is websites, to be designed and completed by the end of the semester.

EXPERIMENTAL DESIGN AND PROCEDURE

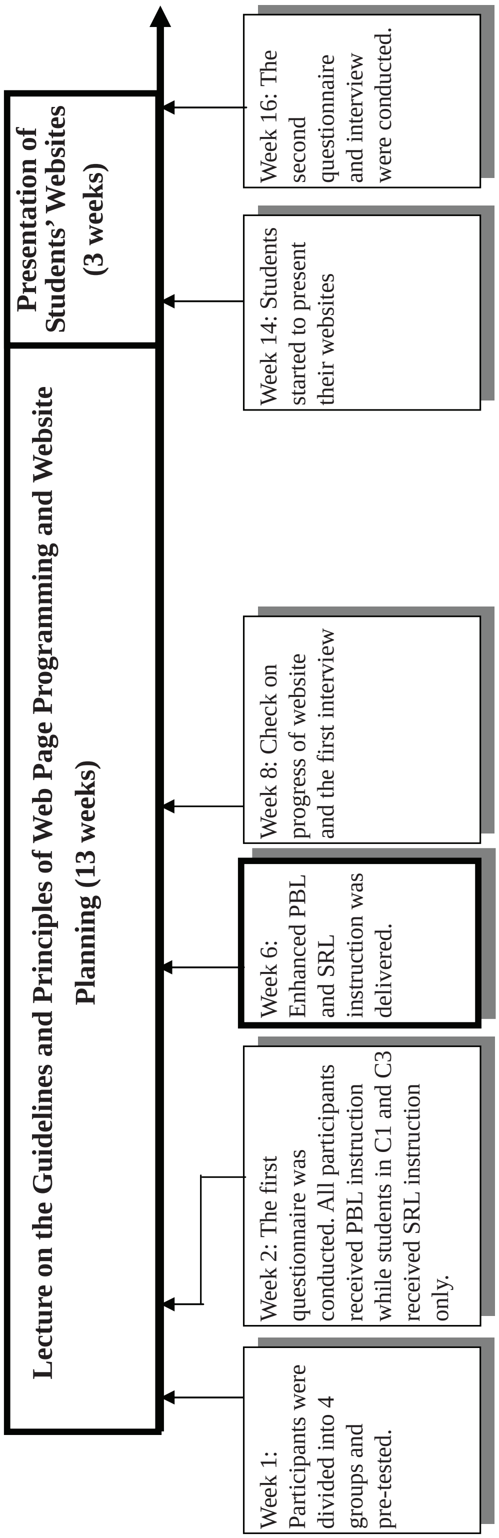
For this study, we redesigned our course and adopted innovative teaching methodologies and technologies to help students develop their practical computing skills. We explore whether students in the course 'Web Page Programming and Website Planning' enhance their skills of application software via e-learning. Based on reflection on our earlier research, we re-designed the course and conducted a series of quasi-experiments to examine the effects of web-enabled SRL, web-enabled PBL with initiation, and their combinations on students' computing skills.

The experimental design is a 2 (SRL vs. non-SRL) × 2 (PBL with initiation vs. PBL without initiation) factorial pretest-post test design (see Figure 1). Four classes were selected from two successive years for this quasi-experiment. Participants are randomly assigned to one of the four experimental conditions. The SRL and PBL with initiation group (C1, n=56), non-SRL and PBL with initiation group (C2, n=44), SRL and PBL without initiation group (C3, n=44) are experimental groups, while non-SRL and PBL without initiation group (C4, n=33) is the control

Figure 1. Expected effects of variation in instructional methods

	SRL n	on-SRL
PBL with Initiation	The most significant effect (C1 Group)	Medium effect (C2 Group)
PBL without Initiation	Medium effect (C3 Group)	Minor effect (C4 Group)

Figure 2. The schedule of the course and presentations



group. Moreover, C1 and C2 were conducted in the first year, while C3 and C4 were conducted in the second one. Before the experiment, we first measured students' skills of web page programming and their involvement in this course as a pretest at the beginning of the course. However, there are no significant differences among the four groups. Then, treatments and interventions were applied to students in the four groups according to the different combinations of teaching methods.

Students were divided into teams, each consisting of 5 to 6 members. Each team had to build up a quality website that conformed to the guidelines or principles in the literature and textbook. The schedule of teaching and students' presentations is depicted in Figure 2.

Treatment of Web-Enabled SRL

Students in C1 and C3 received instruction in an after-school course teaching them SRL strategies. The SRL group was gathered in a classroom and a two-hour lecture was delivered discussing how to manage study time and regulate their learning. The content of this SRL course was composed of the four processes addressed by Zimmerman, Bonner and Kovach (1996), that is, self-evaluation and monitoring, goal-setting and strategy planning, strategy implementation and monitoring, and monitoring of the outcome of strategy. Students were taught how to implement these four processes to become more self-regulated learners.

Reflection on our previous experiences suggests the rigid and extra requirements of SRL may result in low achievers' resistance and antipathy to the treatment. Many vocational students have been taught via spoon-feeding since they were elementary school students. It is difficult to require them to take the responsibility for their own learning. Teachers should adopt appropriate and acceptable SRL strategies for students. Keeping records and self-evaluation were the two most-often-mentioned learning strategies (Ross, 1999). Moreover, high-achieving students utilized the strategies of reviewing notes and keeping records and monitoring most often (Zimmerman & Martinez-Pons, 1986). Therefore, in this study we emphasized keeping records, reviewing notes, and self-evaluation when implementing SRL among low-achieving students. SRL students were required to regularly prepare and read the textbook before classes, and to review what they had learned after school. They were also required to record their learning behavior every week. The data was recorded on the course website instead of in their notebooks in order to prevent falsification of records.

Moreover, students who have gotten used to spoon-feeding teaching method would not change their learning habits and adapt to the innovative teaching methods immediately. Thus, the instructor gave enhanced SRL instruction to improve students' SRL and enhance their confidence by illustrating the positive effects of SRL for students from the previous semester of another SRL experiment. Through this link between outcomes of learning the use, or non-use of appropriate strategies, students can learn to believe that desirable learning outcomes are the products of the strategy used. This can encourage students to persist in leaning and use the appropriate strategies (Shin, 1998).

Treatment of Web-Enabled PBL with Initiation

A teacher creates interesting, challenging, and authentic problem situations. Students played the role of Net Programming Develop Engineer in a simulated company. Students in the PBL group were required to build a prototype of their website in the initial stage of this course. After that, the teacher lectured on the guidelines or mistakes and bugs of web pages in each class, then the students started to discuss about how to implement what they learned through online chat room or forum. They had to reconsider and revise their web pages according to the new knowledge they just learned. The knowledge and skills they learned were immediately applied in their products.

In this course, the teacher scaffolded student learning in a systematic manner. In this regard, Barrows' (1992) "whiteboards" model was applied to help students solve problems and learn from the problem-solving processes. The whiteboard served as a focus of concentration for negotiation of the problem and as a forum for students to co-construct knowledge. All students in this study received a one-hour lecture about PBL. The content of this PBL lecture consisted of the four-column chart put forth by Barrows, that is:

1. **Facts:** It holds information that the students gathered from the problem statement such as what the problem is and where it occurred.
2. **Ideas:** This column serves to keep track of their evolving hypotheses about solutions, such as reducing the search time in a website.
3. **Learning** Issues: The students place their questions for further study into this column. In this example, students identify issues related to the technology for designing the structure of the website.
4. **Action Plan:** This column is used to keep track of plans for resolving the problem or obtaining additional information.

The whiteboards model provided a systematic approach to solve problems. Applying this model made the problem-solving processes more feasible for low achievers. Therefore, Barrows' whiteboards model was applied in this study to help students solve problems in a consistent and systematic manner, and learn from the problem-solving processes.

As mentioned above, vocational students have been used to spoon-feeding teaching methods for many years. They usually lack the ability to seek the essential information and solve the problems they face, particularly in a web-based course without the teacher's on-the-spot assistance. In this round of experiment, the teacher initiated his students into the field of web page programming and website planning. He first established students' background knowledge and developed required skills in the initial stage of the course. After students climbed the stiff learning curve and encountered bottlenecks, students were required to gather information and solve problems with Barrows' whiteboards model by themselves.

Evaluation

Before the experiment and intervention in this study, we first measured students' skills of web page programming and their involvement in this course as a baseline. Students completed three Microsoft FrontPage documents as a pretest, and the scores show a uniformly low skill level. Microsoft FrontPage was chosen for the pretest because almost every student in Taiwan learns FrontPage before he/she learns other web page programming software.

Moreover, Zaichkowsky's (1985) Personal Involvement Inventory (PII) was used in this study to measure students' psychological states regarding personal relevance or importance of this course. PII measures three constructs: interests, needs, and values. In the second week, students completed the first questionnaire as a pretest. The difference in students' involvement in this course at this beginning stage among the four classes was not statistically significant. Therefore, it was considered that the students had equal skills of web page programming and involvement when they began this course. In addition, none of them had any experience in taking a web-based course.

Students began to present their websites in the 14th week of the semester. The teacher graded according to Website Evaluation Criteria (Tan & Tung, 2003) and Web Usability (Schaffer & Sorflaten, 1999). All students in one team would get the same grade. Finally, the enhancement of computing skills is the result of one's grade on the website minus one's pretest grade. We tested the differences in students' enhancement of the skills of web page programming under different conditions.

RESULTS

We took grades on students' performance with their websites as a measure of their computing skills. The 'independent samples t-test' was used to compare improvement of grades between PBL with initiation and PBL without initiation groups. As shown in Table 1, students' computing skills in the PBL with initiation group (82.9425) was significantly higher than that in the PBL without initiation group (73.3117). Therefore, it is believed that the effects of initiation on students' skills in web page programming and website planning were positive, and higher than that without, in a web-enabled PBL environment.

Results from Table 2 show that students' computing skills in the SRL group (81.0800) was significantly higher than that in the non-SRL group (75.7305). That is, the effects of web-based SRL on students' skills in web page programming and website planning were positive, and higher than those without SRL intervention.

Finally, data from Table 3 shows that combination of SRL and PBL with initiation intervention a group results in the highest grades among the four groups. The improvement of skills in web page programming and website planning in C1 is significantly higher than C3 and C4, and also higher than C2, though insignificantly. Therefore, we conclude that the effects of web-enabled SRL and PBL with initiation intervention on students' skills of web page programming and website planning are positive, and higher than for those who do not receive web-enabled SRL or/and PBL with initiation.

Table 1. Independent samples t-test: The improvement of grades

Groups	n	Mean	S. D.	F	t-value	df	*p*
PBL with initiation	100	82.9425	10.77606	15.536	5.080	175	.000***
PBL without initiation	77	73.3117	14.45070				

*Note: ***p < 0.001, **p < 0.05, *p < 0.1.*

DISCUSSION

The Effects of Web-Enabled PBL with Initiation

In this study, the instruction of PBL with initiation was found to play a positive role in enhancing students' computing skills. As the data in Table 1 shows, there was a very significant difference between the PBL with initiation and PBL without initiation classes on the skills of web page programming and website planning ($p = 0.000$). This demonstrates that PBL with initiation is good for computer software education in general, and e-learning in particular. It was suggested that traditional lecturers should shift or adapt to problem-based learning and then align constructively in online teaching (Talay-Ongan, 2003). The findings of the present study are similar to those that appeared in previous studies, which revealed that students in PBL treatment groups performed better than those from the control group in a web-based learning environment (Chanlin & Chan, 2004; Shen, Lee, & Tsai, 2007a).

In Taiwan, vocational students have been taught via spoon-feeding since they were elementary school students. They usually lack the skills to gather information and inquire knowledge to solve problems by themselves. If a teacher implements PBL in his class without initiation, it is very difficult for students to adapt to this innovative teaching method; hence it may lead to limited effects. Therefore, we suggest that teachers design their courses systemically and initiate their students into the field of study. Teachers should provide the essential skills and knowledge for students in the initial stage to help them climb the learning curve, and achieve the potential effectiveness of PBL.

The Effects of Web-Enabled SRL

The data shown in Table 2 also support that the difference in students' skills of web page programming and website planning between web-enabled SRL and non-SRL groups was statistically significant ($p = 0.008$). The importance of self-regulated learning and students' abilities to successfully direct their own learning efforts in Internet-supported environments is emphasized in the literature (Winnips, 2000; Cennamo, Ross & Rogers, 2002; Azevedo, Cromley, Winters & Moos, 2004). Thus, strategies must be put into practice to prepare students for the rigors of learning at a distance and increase the probability of retention and success (Chang, 2005).

In general, students in the vocational system tend to have low confidence and motivation in learning (Su, 2005), have low interest and negative attitude toward their learning (Chen & Tien, 2005), spend more time on part-time jobs, do not adequately get involved in their schoolwork, and don't care so much about their grades (Shen, Lee, & Tsai, 2007a). In this specific context of low achievers, teachers may be taking a high risk in implementing e-learning. However, this study supported that web-enabled SRL helped low achievers learn better in an online course, which may lower the risk.

The Effects of Combination of Web-Enabled SRL and PBL with Initiation

With respect to the effects of the combination of SRL and PBL with initiation, we found preliminary support from the results in Table 3. The results show that the effects of combined training in SRL and PBL with initiation on enhancing students' computing skills are positive and higher than for those who did not receive SRL or/and PBL with initiation, although the difference between C1 and C2 is not statistically significant. These results are also similar to those that appeared in Paris and Paris's (2001), Perels, Gürtler and Schmitz's (2005), and Kramarski and Gutman's (2006) studies. To conclude, this study suggests that teachers could apply PBL and SRL simultaneously rather than singly in the modules to strengthen the interaction of SRL and PBL to promote students' learning.

Based on our findings, there is a warning signal for teachers who plan to implement e-learning, particularly in vocational schools. For those teachers who wish to stick to traditional methods of teaching, or adopt PBL without initiation, this may not be a fruitful approach. Students who experienced neither the SRL nor initiation treatments, in C4, had the lowest grades among the four groups, significantly (see Table 3). It is suggested that teachers should redesign their courses, adopt new instructional methods and technologies, and initiate their students into the field of study to fully exploit the benefits of web-based learning environments.

CONCLUSION

SRL and PBL have been applied successfully for teaching in different academic fields for decades. These two instructional methods could make further contributions to students' learning through the Internet. In this study, we re-designed the treatment of web-enabled PBL to include initiation to further the understanding of its appropriate design and potential effects. Moreover, SRL and PBL with initiation were simultaneously applied as web-based pedagogies to help students develop their practical skills in web page programming and website planning. Results were generally positive, showing enhanced student computing skills.

Providing online courses in an environment where Internet addiction looms is a challenge to both instructors and students. Teachers and students may suffer from ineffectiveness resulting from use of traditional instructional methods without appropriate re-design, particularly in online courses. This study provides an intervention in the context of vocational education addressing how to help students adapt and develop practical computing skills. In addition, it also provides specific reference about how to assist students to regulate their learning and further improve their grades. This study may provide valuable insights and shed light on new and effective practices for schools (particularly vocational schools), scholars and teachers preparing for or presently engaged in implementing e-learning.

Chapter 5.25
Hypertinence, Serendipity or Elicitation of Passion for Knowledge?
Some Critical Elements of Online Learning by Using Web 2.0 Resources

Simona Marchi
University "Sapienza" of Rome, Italy

ABSTRACT

Learning processes depend on the socio-technical and regulatory contexts in which professional practices and daily usage take place. These processes develop out of and through various systems of activities, consisting of subjects, artefacts, rules, knowledge, and roles. What happens when the rules governing these systems, the roles, artefacts and knowledge change? For instance, what happens to learning processes when the settings in which practices take place are virtual, when they occur, say, in a blog, or in a community, or on a social networking platform? In this chapter the author intends to examine in detail the specific features of learning processes taking place in these new online environments.

INTRODUCTION

In 2005, Tim O'Reilly published an article on the changes developing in the relationship between the web and its users. Essentially, O'Reilly stated that negotiation between the web and its users was heralding a new era for the Internet (known as Web 2.0), in which users are allowed to interact directly with the web to create user-generated content. This takes us beyond the one-way communication phase (from web to users) and gives users a role of direct involvement in communication. In a very short time, the phenomenon of Web 2.0 applications has exploded.

These applications have encouraged a large-scale shift from 'individual publishing' to 'personal managing', an activity that enables any user not just to create and share content or partly personalize interfaces, but also to design and manage an interface completely or even develop one's own platform to manage a range of resources and/or interfaces. Without underestimating the playful aspect of the use of Web 2.0 resources, it is also worth focusing on the value of online practices from the viewpoint of individual and collective learning, with which the playful aspect is undoubtedly connected.

The rapid changes in recent years have led web users to activate and constantly reformulate their knowledge and practices in relation to a variety of contexts, objects and diverse actors - including in their on/off-line relationships - based on the possibility of generating and managing this 'relational content' in terms of personal/collective managing.

This content, in turn, may take the form of technologies or new media. Web 2.0 resources are technologies-in-practice (Orlikowski, 2000), which structure users' practices through their repeated use and the way they are operated. They are also technologies-in-technology, i.e. technologies-in-practice with a potentially large number of technological actants and hence the possibility of numerous levels of interaction - technological, semiotic, material and reflective - within the same context of practices. And these resources can also be practices-in-technology, i.e. the generation of new technological resources through the experience of their usage.

Some of the most important innovations include tagging, blogging and social networking, and it should be noted that folksonomies, as opposed to traditional taxonomies, have developed within these innovations for the management of information and knowledge. Bottom-up processes concerning the organization of knowledge, in reality, involve the opposition of top-down classification and indexation versus bottom-up methods of organizing and indexing knowledge.

But how to find our way around? The web environment is definitely a hyper environment (hyper as in hyperlink, but also in the sense of enormous, exaggerated). The volume of resources that can be found through the web and the number of possible actions are far beyond our capacity to use them. At the same time, however, the web can also be somewhat inaccurate, scattered, uncoordinated, and often not very pertinent. How can we conceive of learning processes that are visible, recognisable, and based on the use of Web 2.0 resources?

Information Technology (IT) systems, conceived with the aim of creating the conditions and processes to support the development, processing and sharing of information, have not always produced the hoped-for results. Some studies show that we can by no means take it as given that IT investment improves the processes of creating and exchanging knowledge within an organization (Bernard, 1996; Davenport & Prusak, 1998); others point out that people are often reluctant to use new technologies (Markus & Keil, 1994).

We do not believe that Web 2.0 resources alone, given their technological features, can overcome these barriers. However there are grounds to believe, as we shall see in this chapter, that a relationship exists between the socio-technical features of the use of a given technology and the degree to which subjects use, activate, participate in and share that technology. This relationship is spurious in that it is mediated by a number of motivational aspects. These aspects, however, are in turn connected to a series of other factors, including features specific to these same participation practices.

The concepts of Hypertinence (De Kerchkove, 1998), Serendipity (Merton, 1949; Merton & Barber 1958) and Passion (Barbalet, 1996; Solomon, 1993; Fabbri, 1998), as we shall see, help us to specify the forces underlying participation in communities, social networks, blogs, etc. These aspects are not mutually exclusive. Rather, they interact and enable us to understand the tensions within the processes whereby individuals or groups participate in online learning practices.

Therefore, in this chapter, we will regard Web 2.0 resources as a set of practices - discursive, organizational, classificatory, connective, etc. - performed within and throughout certain environments. This way of viewing Web 2.0 allows us to consider its nature as a situated social practice and to take a relational view of the technology involved.

Starting from some experiments in using Web 2.0 resources to foster learning processes in groups of students and adults undergoing training, we intend to highlight the collective and co-structured nature of the learning that takes place in socio-technical and regulatory contexts based on the centrality of interaction. We also, and above all, intend to analyze the reflective processes whereby new rules, new roles and new knowledge (and, not last, new power relations and new identities) are developed, organized and internalized by the 'new virtual techno-subjects'.

The chapter develops from three concepts deemed to be essential to understand the specific features and potential of online learning practices; these concepts are also the three objectives that should be borne in mind in designing learning experiences using Web 2.0 resources. The chapter continues by focusing on a number of significant and critical elements that should be carefully considered and which emerged through experiences that enabled us to 'touch on' the above-mentioned three objectives. Finally some ideas about future trends and conclusive remarks are developed.

BACKGROUND

Web 2.0 resources make it possible to build participation networks based on networks of relations whose most significant aspect, in learning terms, is not just the content presented online, but also, and above all, the ways in which individual subjects connect with each other. If the medium is the message (McLuhan & Quentin, 1967), then the social dimension of connectivity becomes the message of the internet medium. Similarly, social networks become the message of Web 2.0 resources and users become the content of this message. Content that is not the 'object' but, rather, a network itself referring to a system of professional and friendship networks that make the individual subject 'communicable' to the outside world. The creation of expanded communities based on shared interests, in which various Web 2.0 instruments interact, is explained by De Kerchkove using the concept of 'hypertinence' (De Kerchkove, 1998).

Hypertinence is expressed through the exaltation of multiple resources combined with the appropriateness of their content, resulting from interactions that make answers increasingly pertinent to questions (e.g., using certain types of search engines that rely on tags), or through the interaction with other users displaying value of experience, systematic organization, webbed organization, bridge links, and index labels.

As a result of the contributions made by users when reporting and reviewing their knowledge resources, hypertinence represents a further step beyond the results of search engines which, although able to re-create a network of quotations, are merely the outcome of quantitative calculations.

If we consider the concept of hypertinence in isolation, the connecting practices may be 'simple clicks', i.e. they may not lead to the production of an extensive connective intelligence or be collaborative or reflective, and therefore may not be very significant to online learning. This concept needs to be considered along with two others.

The concept of 'serendipity' (Merton, 1949; Merton & Barber 1958) has a fascinating story that began in the second half of the 18^{th} century. It is hard to find a single definition for this word, which can be summed up as meaning to accidentally discover something precious while looking for something else entirely, or to find somewhere you were looking for but in a completely unexpected way or place. The word 'serendipity' was originally coined by Horace Walpole (1722) and derives from the title of an Asian tale, *Travels* *and Adventures of Three Princes of Serendip.* Merton first came across the term in about 1945, again in a serendipitous manner: while looking in his dictionary for a word starting with the same letters, his eye fell by chance on serendipity. He was immediately struck by the way its definition chimed with the sociological importance of the unintentional consequences of intentional actions in the life of society in general, and of unexpected stages in the growth of knowledge.

The 'model of serendipity in scientific research' (Merton, 1949) indicates a process whereby new ideas take hold in the minds of researchers and the conditions are created for the definition of new scientific concepts. It consists of observing an 'unexpected', 'anomalous' and 'strategic' event that provides an opportunity to develop a new theory or expand on an existing one. The three adjectives in italics are central to the definition of the serendipity model (*ibidem*). The first two (unexpected and anomalous) describe the unexpected way we come across new knowledge: an unforeseen observation produces unexpected knowledge since it prompts the researcher to find a meaning for the observation. But this is not enough in itself to complete the serendipity model. The importance of the third attribute (strategic), describing the event encountered in an unexpected way, concerns, more than the unexpected event itself, the act of recognizing the potential research value attributed to it by the researcher. It is therefore more closely linked to the researcher's assessment of the research content. Serendipity should not be taken as referring only to the special abilities of people who are able to find the unexpected. Rather, it should also, and above all, refer to the experience itself: the action performed when encountering and giving meaning to the unexpected.

This brings us to the importance of paying due attention, in sociological and cultural terms, to the circumstances in which serendipity is most likely to occur. At several points in his analysis Merton focuses on what he defines as 'serendipitous cognitive micro-environments', i.e. culturally variegated environments in which the opportunity for prolonged socio-cognitive interactions by individual talents in different disciplines creates the conditions for serendipity to occur. Such environments can even be created intentionally; indeed in this respect Merton spoke of 'institutionalized serendipity'.

This concept and its history, strongly resemble the discovery and learning processes that take place online. More specifically, the strategic dimension and the concept of 'serendipitous micro-environments' reflect an idea of using and combining Web 2.0 resources in such a way as to create environments and participation/connection systems with the characteristics described above, i.e. that are able to foster serendipitous experiences. This concept enables us to expand our capacity to understand new learning opportunities in relation to practices that become significant through online experience itself. The strategic dimension also tells us that these experiences should be conceived in such a way that subjects can attribute a potential value to them with respect to their goals and individual learning, so that they can be recognized as meaningful experiences.

Another concept that is dealt with more and more frequently - albeit in a non-uniform and often contradictory manner - in the reference literature on participation in the online production of knowledge, particularly from open sources, is 'passion'. We shall not cover this concept exhaustively in this chapter, but shall mention the key points that enable us to understand its importance in determining forms of participation in online practices.

Including the concept of passion in studies on online learning practices would seem to go without saying. However, we must consider that organizational studies, that analyze knowledge production processes in groups and organizations, and semiotics itself have both kept the rational dimensions of action separate from its non-rational aspects, often omitting the latter.

Passion here is viewed as a form of emotion (Barbalet, 1996) - debatable as this may be - that cannot be reduced solely to the dimension of feelings or sentiment (Solomon, 1993) and is closely connected to certain situations or experiences. Passion can be considered as a judgement system that is not just directly connected to the individual's values and beliefs vis-à-vis the world but is also, and above all, an active way of structuring and giving meaning to an experience (*ibidem*). Consequently, passion cannot be distinguished from the contexts, relations, and objects with respect to which these judgement systems are activated. The point is to separate the question of passion from its usual opposition to reason and to connect the concept of passion to that of action.

Passion can therefore be conceived as a view of action held by those who are affected and transformed by this action (Fabbri, 1998). But at the same time it is not entirely rational. The irrationality is often connected with the urgency with which the judgement - a mix of concepts, desires, attitudes and beliefs - is formed. This way of conceiving emotions, and passions in particular, enables us to overcome the usually negative vision of emotions found in organizational studies (Thompson, 1967). Spontaneous, free participation in certain online practices, such as the co-generation of content in open source environments, or participation in blogging or social networking practices, is driven by passion for the very activity of participating and producing new knowledge, new discourse, or objects and by the fact of being somehow transformed by this participation.

Time dedicated, the determination to write and take part in discursive practices, as well as sacrifices made in unthought-of hours and during holidays are indices of the desire to assert that something has value and is precious and important (Polanyi, 1958). The discourse on passion, if referred to online learning practices, is linked to narrative practices. Narrativity, which is prevalent in online learning practices, is a way of causing shifts of significance by specifically combining not just words, phrases or propositions, but special 'actants' that then become characters, actors, and so on (Fabbri, 1998). It is therefore a way of creating objects of value. From this perspective, narrativity is the act of configuring meaning through actions and passions.

The performance of Web 2.0 resources, being a set of situated practices, is built on their use, through the relations in which they are inscribed and through the relations inscribed in these resources. Often, this performance can lead to the contexts and contents generated being abandoned when the experience that made them significant comes to an end. The web is full of abandoned identities and places, stories left unfinished, contents forgotten for years but never destroyed by the users who own those spaces. Given the ever growing production of and participation in social media, we can describe the web as being full, to paraphrase the title of a publication by Zygmunt Bauman, of 'wasted identities and places' (Bauman, 2003), meaning both e-waste and uninhabited areas. In the web, performance and distinctiveness are such that there is a huge recycling of identity, *habitus* and context, occurring with the massive production of permanently visible 'waste'.

Active participation, therefore, is closely related to the way the environments of online practices are configured, or, rather, the experience of online practices, which must be able to produce voice (Hirschman, 1970) and above all maintain it in the presence of a high and constant risk of exit. But producing and maintaining voice is by no means simple and cannot be left solely to chance or given over entirely to technology.

Active user participation in online learning practices is closely related to the possibility/capacity to create environments made of human and non-human actors conceived, taking the centrality of the relation as a starting point, in a sort of 'heterogeneous engineering' (Law, 1987) in which the following conditions are satisfied:

- Pertinence with respect to certain learning experience issues and possibility of creating an extensive connective awareness of how we conceive of and classify these issues (*objective pertinence and connective awareness*).
- Presence of wide degrees of freedom and constant possibility - in the presence of an idea of action, study or research - of making significant discoveries by serendipitous routes (*serendipity and projective transformations*).
- Possibility of producing, through relations, objects deemed to be precious and valuable and which activate prospects for action by individuals and the group, who are in turn transformed by these prospects (*effectiveness and individual/collective values*).

As situated social practices (Suchman, Blomberg & Trigg, 1999), Web 2.0 resources can be expressed at one and the same time as the set of relations through which knowledge is produced and takes shape, and as 'mediators' in the activities of users. Therefore, these resources can also be expressed as practices that create meaning and learning situations rising above individual activities and single subjects and technologies. In this respect the concept of mediation assumes a generative meaning since all the 'objects' and 'materials' that are mobilized in heterogeneous engineering are repositioned - as a result of the relations within which they are included, and for the time in which they are included and associated to achieve a given objective (Gherardi, 2008).

SOME CRITICAL ELEMENTS OF ONLINE LEARNING PRACTICES

If we want to understand experiences of learning in virtual space, it is necessary to reconsider how we can conceptualize and describe what is happening in Web 2.0, in order to reformulate, inform and enrich new concepts of our theoretical framework.

'Edit content, research, update object, make new friends, create, expand the network, login, share information, tag contents' and so on, are some of the key elements of activity systems (Engëstrom, Miettinen & Punamäki, 1999) in internet time (Wellman & Haythornthwaite, 2002). The concept of activity incorporates the cultural, motivational, contextual and organizational aspects of action. This set of circumstances gives rise to 'situated activity systems' (Goffman, 1967, 1969; Suchman, 1987) characterized by being composed of sets of interactions between subjects and objects/artefacts which play a part in configuring specific situations.

Wikis, folksonomies, blog, social networks, are not only technological artifacts, neither just pre-existed places/environments for users practices (Burrows & Ellison, 2004). Contexts are therefore emergent effects of actions and interactions between the elements (human and non-human) of which they are composed. The 'non-human' elements are also considered as being co-generated through sets of relations (Latour, 2005). Web 2.0 assumes the characteristics of multidimensional emerging 'enacted environment' (Weick, 1969) brought into and kept in existence, continually up-dated and modified/modifiable through subjects' practices.

The peculiarity and sociological interest of practices reside not so much in their variability but in their repetition and recursiveness (Gherardi & Bruni, 2007), and in their function of social reproduction and identity construction. Artistry, creativity, as well as the capacity and will to innovate, change and invent are nested and develop within this recursiveness. In the case of online learning studies, the point is to bring out the variability and creativity associated with practices that manifest themselves as elementary and repetitive, or technically designed to reproduce place/context. In actual fact Web 2.0 environments change constantly in terms of their content, structure of networks, the outcome of their expressive forms and their effect on participants, even though they are constructed and maintained through practices that reproduce the resources themselves. Also if we can work online collaboratively with persons who have different geographical locations (Korica, Maurer & Schinagl, 2006), in online learning practices we can refer to a situated practice which is only potentially global, the world within everyday reach (Schutz, 1971). We refer, that is, to an activity that both depends on and constitutes the context and is expressed in a system of interactions that is only potentially broad in scope.

Creativity/artistry consequently refers, as we have mentioned, to the link between 'expert action' and 'creation' that occurs each time we find ourselves acting in situations of uncertainty, instability, unique circumstances, or conflicts of values (Schön, 1983). This link is often not fluid or 'natural'; it is fraught with tensions, in which significant situations of high creativity or crisis occur. Artistry is required in all situations where there is not 'just one right way' or a single assessment criterion to be applied in doing things. It is required, therefore, in all situations that appear as dilemmas. In Web 2.0 practices we have to choose continually, we have to construct continuously our interpretations of objects, contents, narratives, relationship, identities.

In the case of online learning practices, the artistry/creativity concept manifests itself in expert yet innovative actions expressing the subject's presence and/or participation, in a situation of constant 'case uniqueness'. Each 'expert action'- from the object/text published, to the comment, to the choice of aesthetic features of the context, and so on - is expressed within a state of tension between reproduction, technical rationality and creativity, as well as innovation of form and content. In this way, it becomes the object of a reflective process of expressing a form of presence. It thus becomes artistry. For instance: the collective construction of ideas and concepts using tags and conceptual maps. Tagging not only makes 'lateral searching easier' (Maness, 2006), but can also generate movements in non-linear directions and improve several structures of connection.

In order to develop 'serendipitous cognitive micro-environments' (Merton, 1949), we can to construct a Web 2.0 laboratory of practices by using different Web 2.0 resources at the same time. This kind of laboratory has different cultural, social and organizational dimensions, is a 'place in action', safe, accountable to organizations, institutions and individuals, in which participants co-construct objects, contents, meanings, relationships, re-design actions.

In the laboratory, the meaning of community, referring to Goffman's dramaturgic model, is closer to what Goffman calls 'équipe' rather than community of practices (Wenger, 1998). In this respect the 'actor' never works alone in the staging process but collaborates with a set of persons who are 'accomplices' in ensuring that the situation appears the way they want/expect it to. The équipe acts as a 'secret society' (an 'invisible society' in the use of Web 2.0 resources) in which all subjects play a part in keeping the secret as to who/how/when/why they collaborate with or on to keep a particular state of affairs and/or situation in existence and up-to-date. The traditional 'place' in which the secret is kept is 'backstage', the private dimension of social action: offline.

Even given this traditional concept of the distinction between public-private/backstage-frontstage with which we also associate the activity of masking and unmasking, Web 2.0 resources can also be viewed as places where anti-dramaturgic social trends develop in which the confine between backstage and frontstage becomes fluid. The place in which the 'secret' is kept can therefore be represented by the public, 'frontstage' or online dimension. This is based on a principle of 'sincerity' rooted not in the distinction between true-false or person-actor, but in the impression and/or content communicated by participants through their actions. In this respect the participant is 'sincere' (or a liar) by definition, since they always show and communicate what they intend on any given occasion to show and communicate, including their silence and 'apparent absence'. In this reversal the bonds creating an *équipe*, in the narrow sense, are weakened, which means that in the face of an 'invisible society' the community becomes a 'visible society' whose members are, in their different ways, accomplices in the same game of presence/absence.

This types of communities are characterized by interaction. From the technical point of view, in Web 2.0 resources public interaction is very often asynchronous and occurs through the screen and through a system of links, tags and references within and outside the same setting which enable users to read, produce (verbally-visually-acoustically), navigate or be silent. This is flanked by another type of private interaction that may also be synchronous (e.g. through chat rooms) and takes place through private messages (PVT, emails), the backstage or frontstage nature of which depends on the content, objectives and forms of the interaction itself.

What emerges, then, is a change in the rules of the 'staging process', or rather of the 'presence-absence' in which the optical effect produced by online learning practices is that of generating apparently dichotomous situations of presence or absence in which technically either the former or the latter predominates. The movement between presence and absence, which should on the other hand be considered in its entirety, is connected with other types of interaction linked primarily to new systems of legitimization or recognition activated in online practices, which in turn are mediated by the rules of the places in which they develop. This means that a community's recognition of the initial status it has conferred on a participant is replaced by a constant redefinition of participation and forms of interaction based on the rules governing the 'approval/acceptance' that participants attain in the context of one or more communities (which correspond to social circles that can be very wide in scope and size).

The tension between 'approval/acceptance' and 'spontaneity' within a community helps to determine forms of participation and therefore of presence-absence, as well as the processes involved in constructing participants' online identity.

Network practices - often voluntary, associative and free - are practices that produce value and objects of value within a community. These can be understood as: 'terms, gestures, behaviours and objects that give an idea of what is happening, what is circulating and what has a density, objectivity and solidity that makes it necessary to alter attitudes, shake up pre-conceptions, change opinions', and adjust practices (Latour, 2007, p. 227).

The value produced in a laboratory conceived for online learning does not reside solely in the activity of producing knowledge, but rather in distributing, sharing and co-generating that knowledge. The various forms this value can take depend on participation and objectives, the fact that it is free, and the forms taken by the gift in interaction practices. The gift (Mauss, 1925), a key feature of online practices, is expressed in terms of objects, content and relations based on recognition of the other and on trust, listening, receptiveness and reciprocity.

Reputation in online learning activities is more than building a 'fanbase' (Beer, 2006). It is built through the play of the opposing forces of inclusion and distinctiveness, and through an awareness and recognition by others of the contribution a subject has brought to the discussion, is surely one of the most important issues at stake and one of the most valuable objects in online social practices. The way we appraise and appreciate the value of the contributions made by the various participants is the basis upon which reputations are built online.

Participants in online learning practices use different types of narratives (Boland & Tenkasi, 1995), stories (Denning, 2001), myths (Gherardi, 2003), that may sometimes include creative forms of narration such as fiction. By fiction we do not mean something invented or imaginary, as opposed to facts and events that have actually happened. We are referring to something that is an integral part of the processes of inclusion and exclusion in online learning practices, participation in discussion and reflection on the meaning of experience. It is connected with the representation of participants' thinking and experience in the form of various sorts of narrative, images, sounds and video (Clandinin & Connelly, 2000).

So participants' narratives are considered 'as if' they were cross-sections of social practice in the narrow sense. Social practices that make it possible to produce an 'alignment' effect and 'provisional order' by constructing an individual meaning mediated with respect to a shared objective - represented by the reason for which subjects are invited to register and take part in an online learning environment -, and also with respect to multiple factors internal to the network practice. In this 'as if' mediated within a set of relations that are constantly questioned and remodulated, reconfirmed, reframed and reviewed, we find two aspects expressed. One is artistry, which is important since it is rooted in participants' experiences as well as being performed through a system of relations also expressed through the use of Web 2.0 resources. And the other is an effect of balance and alignment that is always provisional and is the main object of knowledge production on the web.

Rhythm is a dimension of context that characterizes Web 2.0 resources as practices of social interaction. The rhythm and the configuration of contexts come from the frequency of the actions and interactions. It is closely related to the number of participants and their active presence, and to the ways of managing/moderating the learning process itself.

Building a rhythm that makes presence sustainable is essential to create an alignment between actants that paves the way for processes of co-constructing inclusion and/or exclusion mechanisms and/or knowledge on the web.

This balance is extremely difficult to achieve and above all maintain. The 'daily reproduction of practices is the effect - always precarious and open to negotiation - of three processes: stabilization, institutionalization, and habitualization' (Gherardi, 2008, p. 40). On the web this effect is highly problematic since the activity of knotworking itself leaves learning processes always open to continuous redefinitions This leads to a redefinition of the context and so of the practices themselves. Unsustainable rhythms and non-agreed moderations often correspond to various kinds of 'anti-programme' (Latour, 1987), manifested in different ways, which make collective work difficult and sometimes impossible.

FUTURE TRENDS

Reflection/reflectivity refers here to the idea of developing a new epistemology of online practices (to paraphrase Schön, 1983). It is not possible to resolve the concept of reflection/reflectivity in just a few lines but we shall consider here the accepted meaning most applicable to this chapter. Reflective practice consists of a set of methods that make it possible to construct and/or reconstruct the meaning of actions, events and selection processes which occur in relation to certain situations that are currently taking place or have already occurred.

These methods are intended to foster a 'reflective conversation with the situation' (*ibidem*). The objectives can be numerous and diverse: to bring out tacit knowledge, to encourage individual and organizational learning, to produce knowledge, to build a community of practices, to identify the meaning of decisions made, practices realized and effects obtained, to foster organizational improvement, to encourage an awareness of the motives for participation/non-participation in certain processes, and so on. In the case of online learning practices we find ourselves mainly in an asynchronous situation in which events appear on a screen and seem to have already occurred. The most recent trend is an interest in more creative forms of reflective practice. In other words: *how we can use reflective practice/s to build and sustain more innovative learning, work teams and organisations*? Creative reflective practice/s help us to re-frame and to see things differently. To embrace eclectic pluralism and methodological innovation. The challenge for the reflective learning community, we suggest, is to think about how the critical is embraced within the creative (Ghaye, 2008).

In this sense, we can use the concept of expansive learning (Engëstrom, 1987), which refers to processes activated by subjects in situations that appear to be highly contradictory, or new and unknown. These processes are activated only rarely and concern, in particular, the individual and collective activity of distancing oneself from a specific action setting text in order to build a bigger picture with a view to expanding the setting itself, and in order also to build a broader range of criteria, a wider object of activity. In this, subjects can free themselves from the limits of the setting in which they are acting and in which new criteria for choice and action can be constructed. This is a matter of learning something that is not yet there, in a place where the subject is learning while building a new identity (*ibidem*).

On the basis of the considerations made thus far, we can state that online learning practices are also reflective learning practices if the learning experience:

- Is conceived as a set of situated social practices that occur in relation to objectives that are redefined from one situation to the next.
- Is based on forces of inclusion and at the same time distinction between participating subjects. These forces are in part institutional and in part negotiated through interactions and a redefinition of the ways of being present/taking part.
- Makes it possible for a socially produced and therefore constantly changing reality to emerge, in which participants are immersed and participate by co-determining that same reality.
- Establishes an epistemic yet pragmatic relationship with everyday practice inside and/or outside the community.
- Activates processes of co-constructing knowledge and ways of appreciating and attributing value to the contribution made by each participant.
- Enables individuals and groups to express and organize their knowledge, opinions and objects in an appreciative manner.
- Retroacts on the practices themselves and on modes of participation.

However, there are many difficulties:

- Exclusion mechanisms can be very powerful and may act in non-uniform manner.
- Practice stabilization processes are subject to constant redefining and result in temporary stages of stabilization.
- The rapid obsolescence of knowledge, and experience itself, on the web makes it difficult to identify ways of appreciating and attributing value to the participation and contribution of each subject.
- Reputation is highly important and regulates *participants*' choices in terms of practices, identities and styles of connection. These aspects are variable and may generate tensions, all the more so when relations include heterogeneous subjects and objects.
- Recalcitrant or abstracted/unaligned objects, or anti-programmes, are always present in each online learning practice and may undermine relations or create the conditions for a frequent reformulation of objectives and common values.
- The high degree of variability in using practices of Web 2.0 resources since decisions,

practices and knowledge involve multiple fields of action.

- The tension between silence and the ways of appraising and appreciating the value of individual contributions is the strand along which new forms of online power are played out; these may create a spiralling increase in the rhythm of online practices or else discourage participation.
- The overall effect of online practices might fail to satisfy the expectations of individual participants, who could then decide to abandon the community.
- As the objectives of the community become increasingly stringent and occupy most of the discursive space, the sense of 'citizenship' in certain contexts could decrease, and this could undermine democratic participation. When this happens, any hardening of the coordinators' positions in defining the rules of participating and formulating comments could drive some participants to leave.

CONCLUSIVE REMARKS

Although online learning practices based on the use of Web 2.0 resources can become situated social practices of reflective learning, this does not always happen. The point is to conceive such practices in a way that takes various factors into consideration: promoting the use of Web 2.0 resources is always an intervention so it always produces an effect in the relations in which the practice takes place. It often plays a part in creating, *ex novo*, a context of relations; this changes continually and interacts constantly and unpredictably with participants' practices and choices and, therefore, directly with the technology.

Practices using Web 2.0 resources clearly highlight all these aspects, starting with the procedures for building an online identity. The first outcome of this technology is to produce a user who, while free, is co-produced through interaction with software. But this simple procedure enables us to clarify that the distinction between *users* is generated through a relationship between human and non-human actors (technological/institutional). Participation in a Web 2.0 online learning environment, as we have seen, also requires a more or less tacit agreement by participants, an agreement that is constantly reviewed and renegotiated on the basis of the realignments emerging from interactions.

If we want to satisfy the following three conditions:

1. Objective pertinence and connective awareness
2. Serendipity and projective transformations
3. Effectiveness and individual/collective values

the central issue is not a technological one but is a relational one.

The reason so many complex e-learning systems have failed to produce the hoped-for results is that they often delegate mediation processes entirely to technology and pre-packaged content. The mediation processes are inscribed in the software itself and not co-generated, a situation that negates the epistemic function of network practices and only favours the pragmatic function. Most systems that use digital platforms for distance learning should be defined as e-teaching, rather than e-learning, experiences. What is missing is the relationship. These systems could be defined as 'practices without communities' or 'practices without mediation'. There is a risk that the focus placed on improving the usability of e-learning systems will not resolve but merely hide the problem.

Mediation brings out the complexity of the relations between the different institutions that define the rules of the game in specific activity environments made up of different cultures, access rules and accountability processes. Degrees of freedom, social exchange, improving individual and collective competences, making tacit, no-formal and informal competence accountable, and co-constructing processes of reciprocal recognition and reputation are some of emergent elements of mediations in Web 2.0.

In this way participants' mutual trust is created and constantly tested and their desire to identify with the undertaking and its outcome is expressed. In this respect, knotworking (Engeström, 2008) and constantly appreciating and attributing value to the product of co-generation become essential to the redefinition of relations between participants and the contribution/motivation of each in relation to the common project/objective. The rules of co-existence in an online learning environment, from netiquette to the ethical protocol, also play a role in creating an online community and specifying the rules of access/recognition/reputation and individual and collective contributions.

Reflective and appreciative approach in using Web 2.0 resources can help us. There are three main components of reflective appreciative intelligence: the ability to reframe things in different way, appreciate the positive, and see how the future unfolds from the present. For this to happen, participants need to be persistent, have self-belief, have a tolerance for uncertainty and have irrepressible resilience (Ghaye, 2008).The key question is: *what are our successes and how can we amplify them to build and sustain a better future from valued aspects of the positive present*?

Facilitators have a central role in constructing hybrid environments, bigger pictures, situations where new criteria apply and where participants learn something only potentially present in the setting/environment where they everyday act, precisely while they are co-constructing a new activity. Learning that takes place through online practices configured as hybrid laboratories is both situated, in that it occurs in the context of the settings and activities mentioned above, and at the same time 'expanding', in that it emerges and is activated from a setting that is potentially true/achievable (Marchi, 2008).

KEY TERMS AND DEFINITIONS

Artistry: Individual and collective ability that emerge in situations of uncertainty, instability, or conflict of values.

Hypertinence: Interactions that make answers pertinent to questions.

Passion: Active way of structuring and giving meaning to an experience.

Serendipity: Process whereby new ideas take hold in minds of actors, on things which they were not in quest of.

Reflective Learning: Committed and value-laden action to try to improve particular situations or contexts.

Reputation: Way to appraise and to appreciate the value of the contributions made by individuals.

Situated Practice: Practices performed with other subjects in a context composed of objects and rules.

Chapter 5.26
Blending Virtual Campuses Managing Differences Through Web 2.0 Experiences in Transnational Cooperation Projects

Yuri Kazepov
University of Urbino "Carlo Bo," Italy

Giovanni Torrisi
University of Urbino "Carlo Bo," Italy

ABSTRACT

Starting from the increasingly widespread need to develop effective teaching in complex transnational settings, this chapter presents an innovative blended model with Web 2.0 collaborative learning strategies built in. The model balances pedagogical, technical and content related issues into an ad hoc institutionally designed 60 ECTS (European Credit Transfer System) curriculum of the European Masters in Comparative Urban Studies (E-Urbs). The chapter aims at disentangling the different dimensions involved in the curriculum delivery, highlighting the pros and cons of all dimensions of the model adopted. In doing so the chapter is divided into three sections. The first section addresses the challenges that effective teaching in complex transnational settings has to face, in particular it highlights the crucial need of managing differences. In the E-Urbs project we had 24 students from 14 countries, 5 continents, 6 disciplinary backgrounds, 32 scholars from 9 partner institutions in 8 countries. The second section deals with the way in which challenges and differences have been addressed and describes the dimensions of the blended model the authors adopted, arguing that a sound virtual campus arrangement should address the pedagogical, technical and content related dimensions in a balanced way considering the institutional setting within which they are embedded. The third section addresses the way in which the blended approach has been enriched through a Web 2.0 perspective, promoting p2p (peer-to-peer)

DOI: 10.4018/978-1-60566-358-6.ch014

collaboration in the generation of knowledge. The main argument is that an increasingly fluid society generates and treats information differently and learning agencies should not only acknowledge these differences but should address them with balanced learning models which take advantage of the new 2.0 paradigms. The authors argue that the result of a balanced blended Web 2.0 approach helps to transform the challenges into a resource for each of the stakeholders involved (e.g., students, scholars, partners, institutions) providing an added value in each dimension of the learning process (pedagogical, technical, content related and institutional).

INTRODUCTION

This chapter proposes an innovative blended model in which Web 2.0 collaborative learning strategies have been coupled with a blended approach in order to cope with the difficulties normally faced by online courses such as declining attention over time and the potentially increasing social distance among participants. The model has been developed and implemented during the first year of E-Urbs, a European Master in Comparative Urban Studies[1], funded within the virtual campus stream[2].

The distinctiveness of the model is to provide a balanced system in which different aspects are calibrated in order to provide a 2.0 blended learning environment, based on a very strong tutoring activity. Pedagogical, technical and content related issues have been balanced to construct and sustain an *ad hoc* institutionally designed 60 ECTS curriculum. In the chapter, each dimension has been separately analysed, highlighting the potential problems arising from an "unbalanced" distribution of weights and priorities.

THE CHALLENGE OF EFFECTIVE TEACHING IN TRANSNATIONAL SETTINGS

During the last decade, E-Learning in its various facets has considerably grown (Fletcher, 2004; Waterfield, 2002). Industry, universities and professional schools have experienced the advantages and difficulties derived from this kind of learning arrangement. Some argue that this expansion of E-Learning models is due to the reduction in costs and infrastructure (Munro & Munro, 2004) in particular when compared to traditional face-to-face (f2f) arrangements. Others relate it to the possibilities that the new technology, including Web 2.0 and learning-object style of learning, gives to didactic innovation.

Universities are among the institutions that have used and experienced the most different E-Learning models, exploiting the benefits that virtual arrangements have on campus life (Bacsich, 2004). Increasingly, technology based solutions, including E-Learning and Web 2.0, are considered an answer to the Bologna process[3] and the Europeanisation of higher education systems. The latter ask for new means by which students can experience innovative ways of studying and learning together in a truly European learning community. The European Commission considers this – according to the resolution of the European Council in Lisbon in March 2000 – as a necessary step in order to foster grow and competitiveness in a knowledge-based society (Kok, 2004).

The "virtual campus" becomes, therefore, a new organisational solution for enriching the transnational offer of universities where, thanks to the use of a LMS (learning management system), learning activities are completed either partially or completely online, with the distant/online assistance of the professor and tutors. Different from other kind of arrangements, the virtuality of these campuses facilitates the creation and development of distant learning communities and research programmes. Thanks to technology, designing integrated European curricula becomes easier and virtual campuses might be one of the main instruments for it.

Virtual campuses, however, cannot be directly compared to traditional campuses. They are of a completely new kind, because they offer not only new possibilities of creating and disseminating knowledge for students, professors and tutors, but because they are qualitatively different. Among their main potential strengths we have their ability to unravel and process differences, whether they are cultural, linguistic or disciplinary. This is one of the reasons why they are regarded with much interest when dealing with the knowledge-based society that values information and differences. This is a society where multiculturalism is a fact and thus comparative studies become a necessity. We are living in a society where information is ubiquitous, goods move incessantly, services are global and people continuously migrate. In the 21st century, society is more multicultural than ever. This is not because there are more cultural differences than in the past, but because these differences are endlessly confronted, incessantly related, instantaneously addressed and put in question. As Bauman (2000; 2005; 2008) would say, we are in a fluid-tachycardic society. In this fluid life, words change their meaning and competitiveness and speed become a priority: speed in gathering information, in dealing with complexity and managing knowledge. Universities and other knowledge producing agencies have to cope with this situation, implementing in the learning processes instant communication and new ways of teaching. Comparative studies, where differences are to be studied, valued and jointly analysed become also a fundamental means for competitiveness.

In this context virtual campuses and comparative studies might be seen as unavoidable milestones. But can virtual campuses be considered a possible (good?) answer in dealing with the complexity of a knowledge-based (Kok, 2004) multicultural society? Are virtual campuses well equipped in order to cope with the implicit difficulties that diversity and the need of comparative studies carry with themselves? Which are the main characteristics of the challenges that a virtual campus would need to manage? How is it possible to create and maintain a sense of learning community? And what are the main characteristics that a virtual campus like arrangement has to have in this context?

We will try to answer these questions on the basis of our experiences with the European Master in Comparative Urban Studies (E-Urbs), since:

- It is a virtual campus, as defined earlier;
- It deals with a multicultural and multi-linguistic cohort of students;
- It is organised by 9 different institutions, with different teaching and organisational traditions;
- It uses a comparative approach;
- It makes use of a Web 2.0 approach;
- It fosters a blended approach that relates online, p2p and f2f learning processes one another.

More specifically, E-Urbs strategically deploys the long lasting experience of the partners in comparative urban studies and in online teaching with the aim of institutionalising a truly European curriculum of 60 ECTS. Extensive online teaching (and tutoring) is aimed at encouraging and facilitating both physical and virtual mobility between higher education systems and institutions across Europe. This fosters the underlying principles of the Bologna process and the institutionalisation of a European Higher Education area through the use of an innovative E-Learning environment for higher education (Land of Learning). Moreover, it aims at monitoring the effects on the interactive process and the use of learning objects.

In short, the E-Urbs Master reproduces and intensifies learning processes within a multicultural frame and uses new technologies in order to address differences. From this point of view, E-Urbs has been a laboratory in which the aforementioned challenges have been explicitly faced, in particular the following ones:

Cultural Differences

Twenty four students from 14 countries and 5 continents participated in various activities of the Master[4]. Differences in customs and culture were considerable. Festivities and bank holidays were dissimilar both for the students and the professors involved, as well as their eating habits. Some uneasiness and prejudice was present at the very beginning in the interaction among some students attending the course, especially in relation to sensitive subjects as race, religion and social belonging. E-Urbs became from this point of view a unique laboratory for going multicultural in a technologically mediated (and relatively protected) environment.

Linguistic and Age Differences

A virtual campus involving people from all over the world needs to cope with the language and age differentiation. Our decision was to use English as a working language. All people had at least a basic knowledge of English. This, however, did not iron out the differences in linguistic competence among the students as none of them had English as their mother tongue. The issue became even more problematic when dealing with the writing of the intermediate and final papers where language skills were a crucial asset. As far as the age of the students is concerned, we can distinguish between two different groups. The first one includes students that just finished their Bachelor degree (average age 24). They were looking for a specialisation curriculum eventually to access a Ph.D. programme. The second age group (average age 30) includes mainly professionals. Some of them were working in public or private institutions and dealing with urban issues already, while others wanted to change their professional career.

The Heterogeneity of Institutional Settings

The Master has been organised by 9 different higher education institutions in 8 countries with different institutional constraints, such as, different admission requirements for students, tuition fees, administration habits, procedures that must be fulfilled in order to receive the diploma, a different understanding of the European Credit Transfer System and the Diploma Supplement. National bureaucracies make it difficult to implement common procedures. Often simple and unchallenged issues become insurmountable problems. Can scholars of one university teach in other university of the consortium and can their teaching load be considered as part of their duties? Would this guarantee the fulfilment of the accreditation criteria necessary to establish a Master course? Is it possible to issue a joint degree or a degree that would be recognised by all partner institutions involved? These basic questions heavily influenced the development of the Master course.

The Background of Disciplinary Traditions

Comparative urban studies use a multidisciplinary approach, as many other Master courses nowadays. Students taking part in the Master were coming from different disciplinary backgrounds, from psychology to planning, from sociology to architecture. This situation – despite the high motivation and interest in urban studies of all students – constituted a major challenge, since there was the need to share a basic knowledge on which to build a more specialised understanding of urban-issues.

Physical and Virtual Distance

Virtual-campus-like arrangements make it possible to organise multidisciplinary courses at a distance. This does not mean that distance issues are completely nullified. Keeping the class active and united with a sense of community, while people are scattered around the world has been a major challenge. If keeping a class interested is a challenge by itself in normal learning environments, when the same culture is shared, the language is easily understood and disciplinary background are somehow similar, it becomes a major challenge where these conditions are not given. Motivation seems to be the key issue in both cases, but the absence of a physical gathering and interaction adds further difficulties. As the literature shows, (e.g., Schifter, 2000) interest in forum, chats and traditional virtual methodology tend to weaken over time and the learning community tends to shrink as time passes by. New methodologies were needed in order to cope with these issues.

Psychological Sense of Community

Many of the differences listed earlier and in particular the physical distance among students, made it difficult to create and sustain a psychological sense of community. Living in different contexts, people tend to tie in with their physical environment more than with a virtual course. Nevertheless, a sense of community is a necessary condition in order to guarantee a successful learning context and traditional solutions for this problem are not directly applicable in a virtual campus.

Communication Technologies

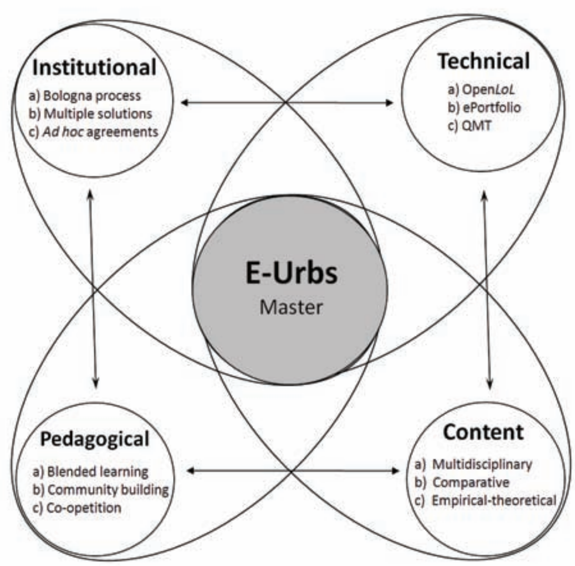
Last but not least, the diversities listed earlier challenge communication technologies. In fact, not all the students had the same IT skills and network performances differed (and still differ) among countries. When the online platform had to be accessed from Cameroon, India or the Netherlands there was the need to guarantee light and user friendly solutions. Moreover, the differences listed earlier required innovative online solutions in order to be addressed adequately and our staff members, students and professors become the beta testers of a new learning software[5] and methodology. For instance we developed co-opetitive (Brandenburger & Nalebuff, 1996; Lihui & Xiaowen, 2005) approaches to enhance distance learning efficacy. As the methodology was innovative and untested, it needed to be put in practice, used and assessed.

Most of the challenges described earlier are common to most virtual-campus-like arrangements and mainly relate to the need of managing differences in a knowledge-based society. In fact, new communication technologies provide us with the means to face the challenges that multicultural and diverse societies pose us in a way that would not have been possible before. Contemporary societies are extremely complex and fluid (Bauman, 2000; 2005; 2008) but they also show an incredible increase in possible ways to address this complexity.

BLENDING LEARNING: AN EFFECTIVE WAY TO MANAGE DIFFERENCES

Reducing the complexity, while keeping the added value of the existing differences, became a crucial objective in designing our learning model. In this second part of the chapter, we will address the challenges described earlier and illustrate how they have been dealt with, balancing the four dimensions of the model: 1) *pedagogical*; 2) *technical*; *3) institutional* and 4) *content*. Their balanced mix, shifts the meaning of the challenges from being critical issues to becoming resources for a mutual enrichment and a "*co-opetivive*" blended approach. In fact, in E-Urbs we addressed and analyzed the effects of specific pedagogical solu-

Figure 1. The E-Urbs Master learning model



tions in teaching and in the didactical organisation as well as the way in which technical solutions could be applied to content considering the countries' existing institutional frames in dealing with diversity.

Our assumption is that the four dimensions we identified need to relate to each other in a flexible yet integrated and balanced way in order to be useful. Keeping this in mind, in the following we will address each dimension, showing how the E-Urbs MA integrated them in an articulated learning model (see Figure 1).

The Pedagogical Approach

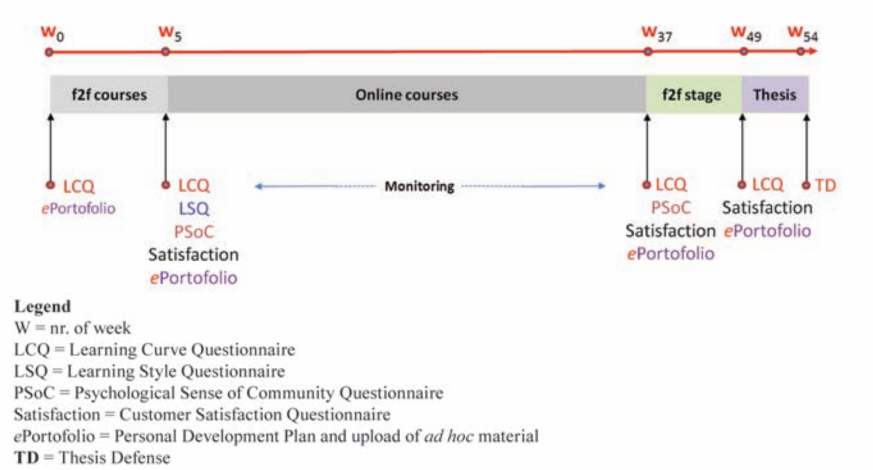
The pedagogical approach we adopted in the design of the E-Urbs Master aimed at integrating three interrelated interaction strategies and tools in order to contrast the problems common in online courses such as the declining attention and the increasing social distance among participants. The three strategies and tools were: a) a blended approach; b) the creation of a spontaneous learning community; c) a co-opetitive behavioural frame.

A Blended Approach

The blended approach (for a critical overview see Voos, 2003) we adopted in the learning path design, integrates f2f and online learning activities and is based on the assumption that both greatly benefit and complement each other. The reasons for this choice are related to three main needs: 1) some disciplines are more complex when they are taught online than others; 2) a truly European curricula might require too much physical mobility; 3) some travelling and transnational exchange was considered vital.

As a solution to these needs, we organised the learning path into three main periods (see Figure 2): 1) a first period (w1-w4) of intensive f2f teaching for a total of 15 ECTS, during which professors, tutors and students met and worked on basic concepts and methods of comparative urban analysis. In this way all stakeholders involved not only developed a common knowledge base, but

Figure 2. E-Urbs' blended learning's structure, monitoring instruments and timeline



also a companionship that supported them during the whole curricula; 2) a second period (w5-w36) of intense online teaching and distant collaborative learning for a total of 27 ECTS; 3) a third period (w37-w49) for a total of 18 ECTS spent at one of the partner Universities where students could work on their thesis and take advantage of the scholarly competences available within the network. The final defence and award ceremony took place in Urbino (w52) and allowed students to physically meet each other again, receive their diploma and confront their research experiences and expectations.

In order to measure the learning effectiveness of the blended approach proposed and to monitor the overall learning process, a monitoring and assessment working group was established[6]. One of its responsibilities was to submit different questionnaires to the students. These included also specific learning curve questionnaires, whose results were used as an indicator of the effectiveness of the learning processes during different periods.

The integrated blended approach adopted during the E-Urbs MA, helped to overcome many of the challenges that a virtual-campus-like arrangement normally has to face. Thanks to the f2f period – targeted to both the acquisition of a common background on comparative urban studies and homogenising the very different competences and interests among students – it became clear that the different disciplinary backgrounds constituted an enrichment with new potential perspectives through which to address urban issues, rather than a problem. The same applied to the age differences among participants. It was clear since the very beginning that the experiences of the older students were perfectly complemented by the more up-to-date studies and the enthusiasm brought in by the younger students. For this reason the management committee opened the Master course to both target groups (students and professionals).

Differences in culture were emphasised and stressed during the f2f meetings. Living together in Urbino, a small university town in Italy, allowed students to experience and to relate with people with very different cultural backgrounds. The small number of participants coming from the same cultural environment, encouraged a group formation dynamic based on other parameters than culture, such as disciplinary interest, personality or simply personal preference. Knowing each other helped substantially to overcome most of the inter-cultural classical stereotypes. This process brought about the rise of several multicultural groups inside the class that also helped to improve language skills, English being the only common language in all groups. Within this context, English was not just strictly used for learning purposes, but also for participating in social gatherings and to be part of the community. This mere fact improved motivation and the language skills of the group. During the first f2f period students had also the possibility to meet their tutors, who accompanied their learning experience during the whole Master programme. The learning community and companionship built during the first f2f month of activity continued and consolidated during the online teaching period. Thanks to this organisation, typical problems afflicting online learning, such us the lack of motivation, weak sense of learning community, etc. (Irizarry, 2002) were substantially reduced. Distance induced difficulties both technical and motivational were weakened by the fact that people already knew each other and could easily compensate the informational gap, normally given in pure online activities, with the previously acquired knowledge of the group and its dynamics. Technical difficulties were also easier to solve thanks to the fact that students and tutors already had the possibility to experiment with the online platform when studying together in Urbino.

The third part of the E-Urbs MA included a f2f interaction. During this time students were asked to move to one of the partners' institutions for their comparative thesis work. There, students experienced different institutional settings, procedures and uses, but at the same time they met scholars, tutors and classmates with whom they interacted online for almost half a year. In synthesis, the blended approach improved the creation and the maintenance of a (quasi)spontaneous learning community that revealed itself as a fundamental element for scholarship throughout the duration of the Master.

The Creation of a Spontaneous Learning Community

The creation of a stable psychological sense of community, which can be defined as the perceived sense of belonging to a specific learning community, played a very important role in overcoming many of the challenges of a virtual-campus-like arrangement.

The blended approach we used in designing the learning path was one of the pedagogical solutions we used in order to promote the creation and maintenance of the community. What we needed in addition, was a series of precise instruments in order to measure and monitor the processes involved in the construction of a learning community. The monitoring and assessment working group (Pigliapoco & Bogliolo, 2007) used two main indicators: the Classroom Community Scale, proposed by Rovai (2002) and based on a 20-item questionnaire and SCITT, and a scale introduced by Pigliapoco & Bogliolo (2007), based on a 6-item questionnaire. Both indicators take into account 4 dimensions:

- Spirit (friendship, cohesion, bonding among students);
- Trust (credibility, benevolence, confidence among students);
- Interaction (honesty in feedback, trust and safety among students);
- Commonality of expectations (commonality of the same learning goal).

The perceived sense of learning community was monitored twice, at the end of first f2f based period (see Figure 1, w5, PSoC) and at the end of the second online based period (see Figure 1, w37, PSoC), to see if there were important changes in the quantity and quality of relations related to the different teaching methods. Even if the psychological sense of community slightly decreased during online courses due to distance, it remained exceptionally high, as did the uniformity of feelings of all participants. Indeed, the quantity of relations among the students during the online teaching period were lower than during the f2f periods, while their quality, i.e., the intensity of friendship and interaction among students, was higher.

Co-Opetition

As we have already maintained, distance poses serious problems to the students' motivation and the development of a psychological sense of learning community necessary to share knowledge in a virtual-campus-like arrangement. In order to foster interaction and engagement and making course-attendance more rewarding, we tried to overcome inhibitors like "forced participation" without interaction and decreased motivation by developing a co-opetitive examination setting. Co-opetition is a methodology that combines cooperation and solidarity with competition in the same given context. Co-opetition has been first developed in a business-market oriented context and it focuses on cooperation between actors in an imperfectly competitive situation (Brandenburger & Nalebuff, 1996).

In the E-Urbs MA we tried to apply the methodology to exams in order to enhance learning efficacy through the promotion of solidarity and competition between students, transforming in this way the differences present among them in a further opportunity to learn from each other. The system was structured in a way that points were given not just to the people who were answering their individual multiple-choice questions correctly, but also to students that were helping others in answering open-questions. Students were organised in small groups of about 3-4 students each and points were given for individual, cooperative and collective outputs with truly Web 2.0 techniques.

The Methodological–Technical Dimension

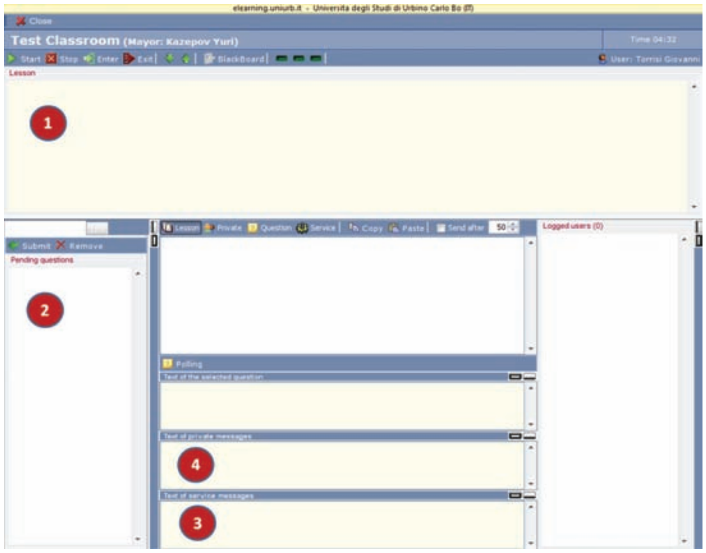
In order to be able to fully deploy the multifaceted pedagogical approach described earlier, we needed to have widely customisable technical instruments allowing us to organise the learning paths as they were developing. For this purpose we used *ad hoc* developed learning objects: a) OpenLol, an E-Learning platform; b) ePortfolio, a tool to promote self-reflection and strategic planning for students' personal and professional development; c) the QMT, the question management tool developed at the University of Urbino.

Open Land of Learning (OpenLol)

The partnership with an IT company (MEC Informatica) in the development of an open Web 2.0 learning platform was a crucial starting point. OpenLOL[7], a LMS based on Java and aimed at the delivery and use of broad and narrow-band Web 1.0 and 2.0 based services, was the result of several years of joint collaboration. The entire online environment has been localised in order to be used in several languages[8], giving everybody the possibility of integrating the familiar feeling of using one's own language in the learning process while keeping a common working language and helping to solve language difficulties.

OpenLoL is based on open standards like linux, mysql and java, and it is a modular environment in which modules and learning objects can be used and/or developed as needed. Among the modules that have been developed and used for the E-Urbs Master we find: a classroom, a shared repository, a forum, a visual lab, an ePortfolio and the Web 2.0 question management tools. The "Classroom" is based on an innovative concept of multi-layer interactive synchronous chat where courses or lessons can be held involving the interaction of professors, tutors, students, technicians

Figure 3. The OpenLol classroom



and learning advisors, yet keeping narrow band compatibility. This easily allows the overcoming of technical connection problems that may arise when people connect from narrow band connections around the world, as the classroom works mainly through layered text-based communication protocols.

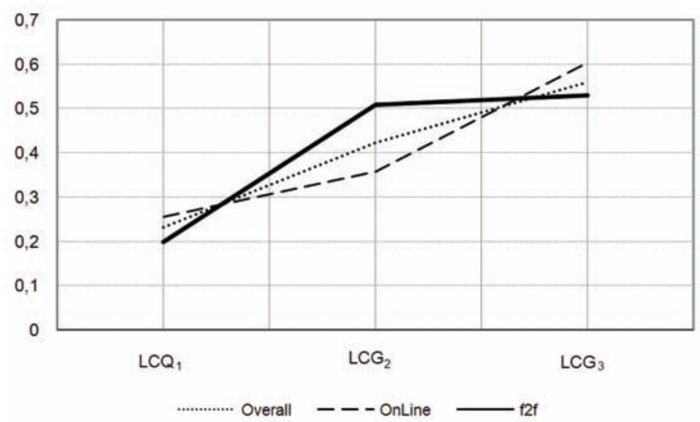
The Different windows of the classroom (see Figure 3) have different functions. In the lesson window (1) the content based interaction between scholars and students takes place. Tutors submit the questions asked by the students via the question window (2). The service window (3) is targeted to informal or service messages, while the private window (4) allows private p2p communication between participants. The coexistence of these parallel interaction layers reproduces a physical-like class arrangement and helps to booster the psychological sense of community and somehow to overcome the classical problems present in distance based courses such as fading motivation. At the end of a lesson, all text written in the lesson window is immediately available for downloading in RTF format, so that the participants may have the transcript of the relevant interaction. An interesting aspect of the classroom is the presence of a real-time blackboard on which users may draw graphs, write, paste pictures, slides, etc. The rest of the participants in the classroom are able to view and can interact on the blackboard in real time. This increases the efficiency of the interaction making explanations more visual.

The software includes other Web 2.0 features which have been used to foster collaborative learning strategies. Asynchronous interactions are taking place on thematic forums and a repository provides a virtual space where both the professors and the students can distribute teaching materials and share documents of any type. This repository becomes the central point of reference for sharing ideas, texts, data and information. Moreover, an online searchable database (called visual lab) helps with the organisation of multimedia content.

The ePorfolio

The ePortfolio is an educational tool used in many universities in Northern Europe and in the United States. It was developed as a methodology to address the growing demand for a personalisation of curricula, competence-focused learning and goal-oriented education. For this reason it is

Figure 4. The learning curve in the E-Urbs MA 2006-2007, adapted from (Pigliapoco et al., 2007)



mostly applied in advanced courses, especially Master programmes. With the Portfolio, a student can critically decide according to his/her goals to attend one particular course and, on the basis of this decision, build a structured archive of the most relevant materials collected during the course. Portfolio is, in synthesis, a methodological frame for self-reflection and strategic planning that some students found very useful in order to exploit the potential of a program for their personal and professional development. An ePortfolio has been included in the E-Urbs MA design aimed at providing students with some strategic career planning guidelines and a constant open channel with the organisation. Furthermore, we received very valuable information about the progress of the individual students, helping us, and the tutors in particular, to offer a more goal-oriented support.

Questionnaire Management Tools (QMT)

In order to manage properly a complex project like the E-Urbs MA virtual campus, there was the need to structure a regular feedback flow using various instruments – including non conventional ones[9] – at different points in time (see Figure 2). For this reason we used the QMT that colleagues from the Applied Informatics Department developed and integrated into the OpenLoL platform. The QMT has a double functionality: firstly, it allows instructors to create their own databases of questions and to build meta-questionnaires made up of questions randomly taken from the databases; secondly, it is a test management tool (TMT), allowing instructors to set-up exam calls, to administer both supervised written exams and unsupervised self-evaluation tests, feedback forms, and allowing students to fill in online questionnaires and to check their scores.

The QMT feedback management tool was used both for indirect and direct monitoring of the learning activity. Indirect monitoring was carried out by means of three types of questionnaires aimed at monitoring Customer satisfaction (CS), Learning styles (LS), and Psychological sense of community (PSoC). Direct monitoring was carried out by means of three types of questionnaires: Self-evaluation test (SE), exams, and Learning curve questionnaires (LCQ). Exams were setup by tutors and instructors as online tests made up of multiple-choice and open-text questions. The tests were submitted at the end of each teaching activity to evaluate students' preparation. Self-evaluation tests were made available to allow students to check their preparation and were associated with each lecture of each course. All self-evaluation tests were the same format as the exams.

As mentioned earlier, a learning curve questionnaire was prepared in order to monitor the effectiveness of the learning process considering the learning curve of the overall class at specific points in time. The questions were prepared with the contribution of all professors teaching in the Master and the learning curve results were calculated in terms of correct answers to a given number of randomly selected questions. Figure 4 shows the average scores obtained by students before the beginning of the Master (w0), after the first f2f period (w5) and at the end of third online period (w37) (see Figure 2 for timing and Figure 4 for results).

The scores confirm a general and decisive improvement of the learning outcomes. The line summarises the results of the overall questionnaire, while the dotted and dashed lines are calculated taking into account respectively the scores related to the f2f and online courses. As we expected, the dotted line grows much faster in the first part, while the dashed line grows faster in second one. There is also a significant cross-talk effect between f2f and online courses. This proves the coherent organisation of the overall programming of the Master with a strong correlation between the different topics of the course.

We used also customer satisfaction questionnaires, which were submitted three times to monitor the satisfaction of the stakeholders and the suitability of the proposed teaching methodology (see Figure 1).

Complementary to the other tools briefly described, a learning style classification questionnaire was used in order to infer how students learn and to make them aware of their learning attitudes and give them advice on how to take advantage of the teaching activities of the Master. Out of the different learning-style classification models which could be used for this purpose – e.g., Honey & Mumford, (1982; 2000), who use 40-80 questions to distinguish between activist and reflectors and between theorists and pragmatists; or by Kolb (1984), who uses 12 questions to classify students in accommodating, diverging, converging and assimilating – we adopted Felder's (2005) model, in which a 44-item questionnaire is used, and 4 dichotomised styles are identified: active/reflective, sensing/intuitive, visual/verbal, and sequential/global. For the results of these questionnaires see Pigliapoco et al., (2007).

The Way Content is Conveyed

In order to put forward an innovative and truly international curriculum, the contents of the course have been designed considering three interrelated aspects: a) the multidisciplinary competences existing within the network of universities; b) the complementarities of theoretical and empirical approaches based on a long-lasting joint-research activity carried on by the project partners; c) the comparative perspective informing all issues addressed from the content point of view. In designing the content of the learning path, we tried to balance these three aspects by organising a general introduction to the basic theoretical and empirical elements of urban studies during the first f2f period, followed by a second period online, characterised by more targeted and specialised topics (e.g., governance, quality of life, planning, etc.). Thanks to this organisation, the different disciplinary backgrounds of the students were considered to be consistent with the comparative spirit of the MA and they were an enrichment from the very beginning. Those students with less related disciplinary background (e.g., psychology) had to face more difficulties at the beginning but were able to catch up, also thanks to the crucial role of the local tutors, overcoming the difficulties and writing a good thesis. Also linguistic diversity among professors, tutors and students allowed the construction of a highly flexible yet powerful multi-linguistic educational model. English remained the working language for common interaction and study, while a variety of languages were used when needed. When comparative research is done, multi-linguistic skills are to be taken into account. Far from being just a problem, language diversity is also useful both for literature review of the social reality that is to be compared and for empirical research (interviews, questionnaires, etc). When language skills were not directly available local and thematic tutors were available.

The different teaching activities were organised according to a modular approach, whose main idea is based on breaking down educational content into small teaching units that can be reused in various learning environments, in the spirit of object-oriented programming. These learning objects are autonomous yet complementary units and can be used also in other learning contexts.

The Institutional Dimension

The institutional dimension was one of the most difficult challenges to deal with in the virtual campus organisation. This is particularly true when we consider the ambitious goal we had to institutionalise the international curricula. For this purpose we addressed three interrelated issues: a) the Bologna process frame; b) the adoption of multiple institutional solutions; c) partners' agreements.

The Bologna Process Frame

In order to design a truly European higher education learning path we wanted to ground it within the frame of the Bologna process so that we could contribute to the development of a European higher education area. From this point of view we needed to foster the approval of a joint E-Urbs MA degree. However, different national regulations and highly bureaucratised systems made this goal extremely difficult to attain. We organised several f2f project meetings, where we also invited representatives of the administration in order to better deal with the difficult legal and administrative issues we needed to address. This helped us partly to overcome the classical division that can be found in most universities between teaching and administrative staff, even though, despite all expectations, the existing legislation and universities internal procedures do not always comply with the Bologna process.

Multiple Institutional Solutions

In this context, all parties involved worked together with the common objective of finding the best possible solutions given the existing constraints related to legislation, bureaucracy and internal rules. Multiple solutions were found, ranging from a joint degree among two Universities, a double degree with other two universities and the mutual recognition of ECTS credits acquired during the MA course by all parties involved.

Partners' Agreements

From the administrative point of view, the multiple and flexible solutions mentioned under 'multiple institutional solutions' were not easy to achieve and required *ad hoc* agreements with the partners. The final diploma acknowledged the contribution of all institutions and the specific *ad hoc* solutions. Moreover, the E-Urbs consortium also issued the Diploma Supplement, in order to increase the transparency and recognition of qualifications across Europe in line with the Bologna Process. The latter offers important additional information on the learning path, describing the level and nature of the qualification attained by the students in order to ease the access to further studies and/or employment.

The Risks of Unbalanced Virtual Campuses

Keeping a dynamic balance can be very difficult and an accurate and strong coordination is needed in order to face and overcome the challenge of the existing differences, whether they are cultural, linguistic, and institutional. Considering one single dimension isolated from its synergic effect with the others would produce an unbalanced virtual campus and would affect the learning results. Focusing too much on didactics might produce excellent learning material, but if this is done without considering the synergic effect with the technical requirements of accessibility, students from African countries with no broadband connection, for instance, might not access videos or other multimedia content. Underestimating the institutional dimension, would not guarantee the achievement of an internationally recognised diploma degree, making the pedagogical results obtained less spendable (or not spendable at all) in the European context. If the technical dimension outweighs other aspects and contents tend to be left behind, students would have the means, but not enough value added in terms of knowledge. All this implies the following risks:

- Too much "pedagogy" → pedagogism: The pedagogical approach, and the consequent organisation of the learning activities, is a crucial dimension of the success of a virtual campus, but needs to be fine tuned in relation to the other dimensions to be effective in its objectives, otherwise it remains a mere expression of pedagogical theory.
- Too much "technology" → technicism: The belief that newer and more recent technologies are simply "better", might overestimate the role of the technical means in order to organise a virtual campus, fostering a blind acceptance of the online learning platform developments and completely forgetting the pedagogy that should direct its improvements.
- Too much "institution" → Bureaucratisa tion:Bureaucratisation puts an excessive attention on procedures and formalities, blocking potential institutional innovation. If every stakeholder within a large consortium is not willing to interpret its own rules and procedures with a problem-solving oriented attitude, the institutional building process entailed in the vision behind the Bologna process would not progress.
- Too much "content" → eclectic disarticulation: An excess of unstructured information would be highly ineffective. The added value of a well organised learning path relies on the fact that information is focused and needs to be integrated in its modules (pedagogy), transmitted (technology) and recognised as valid (institutional dimension).

In synthesis, the need to relate each dimension to one another becomes not only a crucial element of the blended approach we adopted in order to avoid the risks just described, but also to maximise the outcome in terms of quality and effective teaching.

ENRICHING THE BLENDED APPROACH WITH WEB 2.0 OPTIONS

As we maintained in the previous section, the flexible blended approach we adopted was crucial in overcoming the complex challenges faced by the E-Urbs Master course. Yet flexible integration of f2fs and online learning experiences are not always enough to address in an adequate way, some of the challenges involved in distance learning. From this point of view, the Web itself is going through a major change. The new emerging Web 2.0 characteristics are modifying the way in which information is treated and blended approaches improve substantially when integrated with a Web 2.0 perspective. The expression "Web 2.0" became famous after the first O'Reilly Media Web 2.0 conference in 2004. It does not refer to any technical update of the World Wide Web technologies, but it is a new way in which users can take advantages of the Web. The classical role division present in the mass media system between the information producer (i.e., writer, movie director, and singer), the information editor (i.e., editor, major, and publisher) and information user (i.e., reader, viewer, and end-user) suddenly tend to collapse. With youTube you can broadcast yourself without any filter; with Wikipedia you can write an encyclopaedia, not just read it; with del.icio.us you can directly share your bookmarks. No major, no editor, no publisher, no filters. All information is collectively created and immediately shared. Distribution of information loses its hierarchy and it becomes peer-to-peer based. Keywords of the Web 2.0 become wikis, p2p, blogs, folksonomies. As Högg et al., (2006) explained the Web 2.0 is a philosophy that mutually maximises collective intelligence, producing in this way added value for each participant by formalised and dynamic information sharing and creation.

Such a huge change in the way in which the Web is used and conceived could not have any impact on virtual-campus-like arrangements. The E-Urbs MA in Comparative Urban Studies, with students with very different backgrounds and age groups, eager to learn from each other and to share and compare their experiences, was the perfect opportunity to test a Web 2.0 approach in an E-Learning environment. E-Urbs changed traditional learning paradigms based on a clear hierarchy between the professor (who possesses the information) and student (who has to receive it), in order to take into account the new peer-to-peer learning paradigms in which the information increases its value and richness because each participant shares it, regardless of his/her statutory role. Albeit this major change in the way in which society treats information cannot be forgotten, a learning agency such as a university needs to retain some structure and integrity against the relativism of the informational value. Old learning paradigms need to be updated, but Universities remain the institutions where the means for processing information are given and where it is learned how to distinguish among the indefinite informational flow of information that the Internet presents to us.

In order to integrate Web 2.0 approaches and to address learning needs more adequately, as we have already seen in the previous paragraphs, we used several tools and methods: a) we incorporated a co-opetitive learning approach, as an innovative way of fostering p2p collaboration and motivation for achieving excellence; b) we developed a visual laboratory on “changing cities”; c) we used a repository for sharing documents, gray literature, provisional papers, etc.

A Co-Opetitive Approach

As described in the previous section, co-opetition is a methodology that combines cooperation with competition by contextualising and promoting both among students. In this way, existing differences are transformed in further learning opportunities, in the spirit of Web 2.0. Nonetheless, the method we adopted retains some more traditional elements since it is structured in a way in which students’ performances can be clearly assessed by the professors of the single courses. The co-opetitive exam we proposed, was made up of two parts: i) the first part with 5 multiple choice questions to be answered in 20 minutes on an individual basis; ii) the second part with one open question to be answered in a collaborative way within a given number of small groups. Important elements for the assessment of the outcome of the second part of the exam were: a) all members of the group have to agree on the answer; b) the division of the tasks should be discussed online within the group; c) the author of each part of the answer should be identifiable, i.e., we should be able to allocate the different parts to the different members; d) All interactions (i.e., including the discussion on the answering strategy) are tracked and considered in the assessment of the exam. Responses by the students to the learning methodologies we proposed were enthusiastic, not just for the excellent results they achieved and for the further consolidation of the psychological sense of the community they felt to belong to (as a side-product), but also because they were feeling that the over-all system was enriched by their own contribution and discussion.

The Visual Lab

The comparative Urban Visual Lab implemented in the E-Urbs project pushed the p2p 2.0 collaborative approaches even further. It allowed MA participants to develop collaborative and comparative projects using images of several cities (both European and non-European). The visual activities were focused on taking and collecting pictures that would illustrate the way in which different sociological concepts embody themselves differently across various cities. Participants were using visual tools to reach a deeper and richer understanding of urban societies and the respective metropolitan areas. Since the images produced were available in an open wiki-image-gallery, they were used not just by the Master participants, but also for teaching all over the world. Currently, in the E-Urbs MA the visual lab contains more than 9,000 pictures on more than 40 cities around the world uploaded by more than 100 MA and PhD students in Urban studies around the world and classified according to 9 main thematic issues relevant to urban studies[10].

The Repository

Inside OpenLoL, E-Urbs students had access to a digital repository where they could download most of their teaching materials. The peculiarity of this repository relied not so much on the instrument itself rather on the way in which we decided to use it, giving to each student the possibility to share his or her own resources, being those links, notes, pictures or draft papers. The Web 2.0 is not based on a major technological change, but much more on the way in which users make use of technology for collaboration. The repository is the digital place in which the concept "collaborative learning" became real, giving to the E-Urbs learning model a solid ground on which to base its collaborative memory.

FUTURE AND EMERGING TRENDS

As we have seen throughout the chapter, the results of integrating a blended learning approach with Web 2.0 features can be considered a viable model for experimenting and implementing new learning (and social) environments. Web 2.0 is changing the way in which information is constructed, (re) produced, distributed, consumed, allowing users to take advantage of the changing paradigms of the information society, in order to enhance the quality of the learning process. In synthesis, blended approaches improve substantially when integrated with a Web 2.0 perspective. This needs to be considered not just as an emerging trend, but a requirement for any future E-Learning development that has the ambition of being an innovative and effective means of education. The knowledge-based society has changed the way in which information is conveyed and learning agencies cannot simply avoid dealing with the issue.

Coherently, future trends in this domain will integrate electronic and paper based knowledge and between traditional and new paradigms of education. This will mean that most of the courses offered by Universities (or other learning agencies) are moving towards some form of blended 2.0 learning approach. Traditional face-to-face courses become each day more electronic dependent (assignments and research is done most of the time on the Web) as well as traditional online experiences need some physical attachment in order to be effective. So much differentiation is moving toward many variations of a single model in which physical presence remains fundamental but just if it is coupled with the e-means that allow students to navigate and process the fluidity of this new knowledge-based society.

As counter-intuitive as it may seem, the Web increased the number of flights instead of diminishing it, as virtual mobility has amplified physical mobility and computers (and printers) have boosted the amount of printed paper, the evolution of the Web 2.0 complexity and fluidity is calling for more structured and organised learning agencies that will have the responsibility not just of using, but also of educating people in dealing with the new information paradigms.

CONCLUSION

The main objective of the E-Urbs project was to contribute to the development of a higher education area in urban studies in Europe taking advantage of the use of virtual campus arrangements. The E-Urbs learning model, which characterises the virtual campus we described in this chapter balances different strategic dimensions like the institutional, technical, pedagogical and content related ones into a flexible blended approach with new co-opetitive Web 2.0 learning paradigms built in. The outcomes of the complex and interrelated arrangements resulting from the monitoring processes reported in the last two sections are rewarding and consistent with our initial hypothesis: a balanced approach taking into consideration the relevant dimensions not only adequately addresses the challenges of distant and transnational teaching arrangements, but also fosters a strong sense of psychological community that also improves learning effectiveness by building a collaborative learning culture.

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of Web technologies. Particular contributions address Web software engineering and Web-enabled employee life-cycle process management. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how Web technologies can inform their practices and behavior.

Chapter 6.1
Enterprise 2.0:
Collaboration and Knowledge Emergence as a Business Web Strategy Enabler

ABSTRACT

The Web is becoming in many respects a powerful tool for supporting business strategy as companies are quickly becoming more and more reliant on new Web-based technologies to capitalize on new business opportunities. However, this introduces additional managerial problems and risks that have to be taken into consideration, if they are not to be left behind. In this chapter we explore the Web's present and future potential in relation to information sharing, knowledge management, innovation management, and the automation of cross-organizational business transactions. The suggested approach will provide entrepreneurs, managers, and IT leaders with guidance on how to adopt the latest Web 2.0-based technologies in their everyday work with a view to setting up a business Web strategy. Specifically, Enterprise 2.0 is presented as a key enabler for businesses to expand their ecosystems and partnerships. Enterprise 2.0 also acts as a catalyst for improving innovation processes and knowledge work.

INTRODUCTION

There is no doubt that the Web is in many respects a powerful tool for supporting business strategy. Emerging Internet technologies continue to enable businesses to expand their ecosystems and partnerships. This, however, introduces additional managerial problems and risks that have to be taken into consideration to avoid being left behind.

This chapter explores the Internet's present and future potential in relation to information sharing, knowledge management, innovation management, and the automation of cross-organizational business transactions. It points out how a business Web strategy that takes into account this potential will help not only to improve the existing information sharing and knowledge management processes, but also to protect investments in technology that would otherwise have resulted in expensive failures and severe losses. The suggested approach is based on the emerging Web 2.0 vision and will help to minimize the risk of key information and knowledge being lost or simply not being available on time for the stakeholder, projects started and never finished, worse time-to-market, results not meeting expectations, failure of global, cross-organizational IT integration processes, or even incoherencies between technology and company strategy or structure and so on (Argyris, 1998, pp. 98-105). All managers, and particularly IT leaders, must be aware of this new potential and its implications in order to come up with innovative and effective answers to both known and new problems related to information sharing and knowledge management within their organizations (McAfee, 2006).

The chapter's contents are designed to guide entrepreneurs, managers, and IT leaders through the adoption of the latest Internet technologies, such as Web 2.0, Enterprise 2.0, and the global service oriented architecture (SOA), and their application to their everyday work with a view to setting up a business Web strategy. Musser and O'Reilly (2006) claim that by defining and following a set of architecture building blocks, architectural design decisions, and normative guidance, they can build flexible, extensible, and reusable solutions for exploiting the best features of the emerging Web 2.0 technology suite to achieve the best return on investment (ROI) by leveraging the upcoming Web of user-centered services.

BACKGROUND: THE ADVENT OF ENTERPRISE (WEB) 2.0

There are several different definitions of Web 2.0 (a.k.a. *social networking*) that mostly only describe certain aspects of the overall concept. Tim O'Reilly (2007), who originally coined the term, initially identified seven major characteristics inherent to the Web 2.0 concept. First, the Web is considered as a platform for building systems that do not necessarily have a specific owner and are "tied together by a set of protocols, open standards and agreements for cooperation." Harnessing Web users' collective intelligence represents the second major paradigm. This promotes architecture by participation and democracy and encourages users to add value to the application as they use it. The ownership of mission-critical data is regarded a further cornerstone of numerous Web 2.0 applications. Fourth, O'Reilly propagates the end of the software release cycle as another central paradigm. The use of lightweight programming models that allow for loosely coupled systems and applications, the provision of software above the level of a single device, and the realization of rich user experience represent the last major paradigms inherent to the Web 2.0 concept. Besides such analyses that properly describe parts of the super-ordinate concept, there are only very few comprehensive scientific definitions available. An in-depth investigation of numerous different, successful Web 2.0 applications conducted by Högg, Meckel, Stanoevska-Slabeva, and Martignoni (2006) condensed the respective characteristics into the following statement, which serves as underlying definition for this chapter: "Web 2.0 is defined as the philosophy of mutually maximizing collective intelligence and added value for each participant by formalized and dynamic information sharing and creation" (pp. 23-37).

The Enterprise (Web) 2.0 concept (henceforth referred to as *Enterprise 2.0*) is related to its big brother Web 2.0, because, to a certain extent, it can be viewed as many existing Web 2.0 consumer-oriented services maturing to include features that are important for enterprise users. Enterprise 2.0 represents on its own a new paradigm in which employees, regarded as *knowledge workers*, are coproducers of content, knowledge, applications, and services. Therefore, there is an imperious need to revisit and reconsider the very definition of knowledge worker during this chapter, because it is used extensively throughout the chapter from Davenport's (2005) viewpoint, that is, to refer to employees, partners, suppliers, customers and other possible stakeholders. Enterprise 2.0 provides enterprises with new models and tools for emergent collaboration and cocreation. Enterprise collaboration is thus being enhanced by virtual communities that leverage social linking and tagging tools (e.g., tools for social networking, social bookmarking, and social search), user-contributed content management platforms (e.g., enterprise wikis, blogs, and forums), tools that leverage user opinions (e.g., tools supporting comments and voting), subscription-based information distribution tools (e.g., Enterprise really simple syndication [RSS] feeds), user-centered services (e.g., mash-up- and pipe-based services), and so forth (Drive et al., 2004).

These digital platforms are already popular on the Internet, where they are collectively labeled Web 2.0 technologies (Laso, 2006). Now though, a number of Enterprise 2.0-based collaboration platforms are beginning to proliferate. These platforms are aimed at providing enterprises with specialized subsets of these out-of-the box capabilities (Coveyduc, Huang, Ostdiek, & Reif, 2006; Intel Corporation, 2006). These new collaboration platforms provide enterprises with an ecosystem of knowledge workers who collaborate to develop capabilities by collectively generating, sharing, and refining information, business knowledge, and services. Enterprise 2.0 collaboration enables firms to leverage desirable Web 2.0 attributes, including harnessing collective intelligence and architecture by participation.

The user's production is now primarily based on the customization, composition, remix, and reuse of existing material, such as sampling or mash-ups, by the employees themselves. Enterprise 2.0 technologies have the potential to usher in a new era by making both information sharing, service provision, and consumption, and knowledge work practices and their outputs more visible. At the same time, they provide support for the extraction and the emergence of both knowledge and organizational structure.

In representation of the Gartner Group analyst firm, Smith (2006) recently predicted that by 2008 the majority of Global 1,000 companies will adopt several technology-related aspects of Web 2.0 to advance their businesses. As companies quickly increase their reliance on new Web-based technologies to capitalize on new business opportunities, the industry is showing greater demand for technology experts who can build and manage Web 2.0 resources, including blogs, wikis, forums and user groups, and mash-up enabler tools to centralize the management of all of these resources, supporting technology and knowledge experts' work.

RESEARCH FRAMEWORK AND OBJECTIVES: FOSTERING INNOVATION THROUGH AN ENTERPRISE 2.0-BASED BUSINESS STRATEGY

As global market opportunities, competition, and availability of human resources increase, enterprises are assigning high strategic priority to speeding up innovation, even by modifying their own business and global presence strategies. Enterprises want to speed up innovation to improve their market and business opportunities in the fierce global competition by collaborating and cocreating with partners and users (Coveyduc et al., 2006). The desired outcome is improved time-to-market and increased value of more new products and services. The emergence of Enterprise 2.0 Web-based platforms provides enterprises with new models and tools for collaboration and cocreation.

Enterprise collaboration can be fostered by virtual communities that leverage user content sites (e.g., Wikipedia, Flickr), social linking, tagging, and searching tools (e.g., MySpace, del.icio.us), and sites that leverage opinions of all who participate (e.g., Amazon ratings). Enterprises already leveraging cocreation are eBay API and SalesForce.com AppExchange. These platforms, as Weill and Ross (2004) note, provide enterprises with an ecosystem of partners, suppliers, and customers collaborating to develop capabilities by integrating knowledge and services. Enterprises want a solution that delivers these capabilities out of the box.

The key idea behind Enterprise 2.0 vision, and the lesson many businesses must learn, is that next generation IT systems must be conceived to acquire the knowledge they operate on directly from who really has it, that is, the employees (seen as knowledge workers) and from the operation and communication processes employees enter into (Morris, Pohlmann, & Oliver, 2005). The knowledge of a business has less to do with the IT infrastructure than with the employees themselves. The IT infrastructure must be capable of extracting and managing that knowledge for it to evolve and adapt to the business processes. Any other means to model and exploit the business knowledge will never be flexible enough. If user knowledge changes (and it does change), the IT infrastructure must seamlessly adapt to such changes.

In any case, the design of both traditional and Enterprise 2.0-based solutions has focused primarily on creating a structure that supports common processes and stores information to assure that it is easy to find, reliably available, and backed up. They all have been conceived under the premise that teams need to focus on their core business rather than IT issues. The entire operating environment has therefore been traditionally subordinated to IT departments. Nevertheless, this approach has proved to have a number of collaboration-related drawbacks that slow down the pace of innovation. Knowledge workers are thoroughly acquainted with routine procedures and are capable of extracting automatic behavior, suggesting improvements on the IT systems they use through their operating environment and, more importantly, innovating new operating procedures. Operational innovation is an essential requirement in today's competitiveness-driven business markets, enhancing as far as possible collective intelligence-based knowledge work.

With this in mind, this chapter's main objective is to elaborate on the synergies the Web 2.0 concept and several IT technologies have with regard to the enterprise innovation. Web 2.0's focus on the inclusion of human beings and the exploitation of users' collective intelligence is considered a key enrichment of the knowledge emergency within enterprises. This research objective will be contrasted with relevant literature reviews. The remainder of the chapter is structured as follows. First of all we revisit the notion of knowledge worker and its duty, analyzing its features, needs, and problems they find in their daily innovation effort. In this section we elaborate on factors that can facilitate or instead inhibit a knowledge work process. We then present solutions for fostering enterprise innovation based on Enterprise Web 2.0 ideas and technologies, a pragmatic guideline recommending the alignment of the business strategy exploiting Enterprise 2.0 advantages and the application of this idea to other key Web strategy areas. Finally, the final section concludes this chapter and presents a brief outlook on future trends.

ISSUES, CONTROVERSIES AND PROBLEMS IN ENTERPRISE COLLABORATION AND KNOWLEDGE EMERGENCY

Knowledge Work Revisited: Novel Ways to Foster Innovation through Social Capital and Collective Intelligence

Collective intelligence has existed for at least as long as humans have. Ancient social groups, nations, and modern corporations all act collectively with varying degrees of intelligence. But this ancient phenomenon called innovation emergence is now occurring in dramatically new forms. With new communication technologies, and especially the Internet, huge numbers of people all over the planet can work together in previously unsuspected ways. For this reason, it is more important now than ever before to have an in-depth understanding of collective intelligence to be able to create and take advantage of the new possibilities. Our current definition of collective intelligence is "*groups of individuals doing things collectively that seem intelligent*" (Davenport, 2005).

In general, "collective intelligence" is a *perspective* that can be applied to many different kinds of phenomena. For instance, this perspective suggests another way of thinking about things like "firm productivity," "organizational effectiveness," "teamwork," "firm profitability," and "leadership." When people hear the term "collective intelligence," they tend to assume that it implies individuals giving up their individuality to be somehow subsumed in a group or team. This is *not* what we mean. Collective intelligence, as we understand and explore it, is not about false consensus, hive minds, cults, or groupthink. Collective intelligence relies upon and emerges from a synergy between the individual knowledge, creativity, and identity of its constituent parts (Brown & Duguid, 2000). In its highest forms, participating in collective intelligence processes can actually help people self-actualize while solving collective problems. This collective intelligence is developed within enterprises by the innovative engines called knowledge workers.

As we mentioned above, nowadays enterprises need to accelerate innovation to improve their market and business opportunities in global competition, and therefore it becomes essential to revisit features, profiles, and characteristics of key actors in every innovation process, hence, the knowledge workers. This will help in understanding of the relevance of Enterprise 2.0 technologies and models for both improving their work and expanding their productivity, as we will tackle in subsequent sections.

Knowledge Workers. Mission, Relevance and Novel Ways to Improve their Work

There is a range of ideas about what *knowledge workers* are and what characterizes them. Some examples are:

- "The term *knowledge worker* was coined by Peter Drucker some thirty years ago to describe someone who adds value by processing existing information to create new information which could be used to define and solve problems. Examples of knowledge workers include lawyers, doctors, diplomats, law makers, marketers, software developers, managers and bankers." (Fallows, 2005)

- "Knowledge workers use their intellect to convert their ideas into products, services, or processes" (Davenport, 2005).
- "Their main value to an organization is their ability to gather and analyze information and make decisions that will benefit the company. They are able to work collaboratively with and learn from each other; they are willing to take risks, expecting to learn from their mistakes rather than be criticized for them." (Davenport & Prusak, 1997)
- "Knowledge workers are continually learning, aware that knowledge has a limited shelf life" (Davenport & Prusak, 2000).

What then is a knowledge worker?

- A problem solver vs. a production worker
- A person who uses intellectual rather than manual skills to earn a living
- An individual who requires a high level of autonomy
- A manipulator of symbols; someone paid for quality of judgment rather than speed of work
- A worker who uses unique processes
- Someone who possesses uncodified knowledge which is difficult to duplicate
- A worker who sources between the ears
- Someone who uses knowledge and information to add to deeper knowledge and information

Fewer and fewer people are subordinates, even in fairly low-level jobs; increasingly they are knowledge workers. Knowledge workers cannot be managed as subordinates; they are associates. The very definition of a knowledge worker is one who knows more about his or her job than anyone else in the organization (Davenport & Harris, 2007).

According to Nonaka and Takeuch (1995), what motivates workers—especially knowledge workers—is what motivates volunteers. Volunteers have to get more satisfaction from their work than paid employees precisely because they do not get a paycheck. They need, above all, challenge. They need to know the organization's mission and to believe in it. They need continuous training. They need to see results. Implicit in this is that employees have to be managed as associates and/or partners, and not in name only. The definition of a partnership is that all partners are equal.

Davenport (2005) elaborates on this idea when stated that the productivity of the knowledge worker is still abysmally low. It has probably not improved in the past 100 or even 200 years for the simple reason that nobody has worked at improving the productivity. All our work on productivity has been on the productivity of the manual worker. The way one maximizes their performance is by capitalizing on their strengths and their knowledge rather than trying to force them into molds.

Types of Knowledge Workers

From the practical perspective outlined in this chapter, it can be very useful to consider three separate types of knowledge worker: "core knowledge workers," "*high-end* knowledge workers," and "everyone else."

- Core knowledge workers are those in specific "knowledge management" roles and enterprise duties. Examples of these kinds of roles include chief information/knowledge officers, librarians, knowledge managers, content managers, knowledge analysts, information officers, and so forth.
- "High-end" knowledge workers, or those with the highest degree of education and expertise, would seem to be particularly important to enterprise innovation. They are the scientists who develop the new products, the professionals who plan and sell the big consulting or legal projects, or the hardware or software architects who

envision and deliver the new product line. In the knowledge economy, these should be the horses that pull the plow (the people to whom we should look for the new ideas, products, and services that fuel revenue growth and ensure organizational longevity) (Davenport & Harris, 2007).

- Everyone else is all the other knowledge workers (e.g., dentists, doctors, nurses, managers, pharmacists, technicians, administrators, etc.). In short, everyone in the organization engaged in some form of "knowledge work."

Of course, there is not always a clear dividing line between these classes, but the distinction can be a helpful one at the start. It can be particularly useful for helping people to understand that everyone in a company is a knowledge worker to some degree, and knowledge work is everyone's responsibility, not just that of a few people with "knowledge" or "information" in their job title.

Features of HEKWs (High-End Knowledge Workers)

1. They control their own work structure; high-end knowledge work remains relatively unstructured and autonomous. No one generally tells these workers where to work, when to work, or what specific tasks to perform during work.
2. They are highly collaborative.
3. They work in multiple settings.
4. They do individual and group work.
5. They have high levels of passion, power and occupational mobility.

Knowledge Types Managed by Knowledge Worker

Here is one classification for different types of knowledge.

- **Logical:** There is knowledge that is the result of the understanding of how ideas relate to one another in a domain.
- **Semantic:** There is knowledge that is the result of learning the meaning of words or concepts. Knowledge of words is knowledge of definitions. Such definitions are set out in dictionaries. You can look this knowledge up.
- **Systemic:** There is knowledge of mathematics and geometry, for example, which is the result of learning a system of words, or symbols, and how they relate to one another and the rules for operating in that system. Any claims made that are consistent with those definitions and rules are called knowledge.
- **Empirical:** There is knowledge that comes through our senses. This is empirical knowledge. Science is the best example of a method for ascertaining the accuracy of such knowledge. Scientific knowledge is a result of practicing the scientific method, that is, observation, abduction of a hypothesis, careful observation, refinement of the hypothesis, deduction of a test for the hypothesis, testing and experimentation, and confirmation or falsification of the hypothesis.

In addition, knowledge can be viewed from another point of view as implicit and explicit knowledge.

Informative Channels used by Knowledge Workers

Traditional knowledge management programs attempt to manage the process of creation or identification, accumulation, and application of knowledge or **intellectual capital** across an organization.

By exploiting several informative channels, the guidelines of core knowledge workers can be made accessible for everyone else in the company. This approach looks to emerge and apply collaborative and social knowledge to create a **social capital** across the organization (Lin, Burt, & Cook, 2001).

The following is a list of informative channels used by core knowledge workers in Enterprise 2.0:

- e-mails
- chats
- blogs
- RSS feeds
- portal or Web content
- links and reverse references (links in blogs)
- wiki tools
- folksonomies
- bookmarks (tagged or not)
- documents of every kind, including files in ftp, printed papers, and so forth
- physical communication in person
- physical communication in distance (e.g., phone)
- common applications as enterprise mash-ups

Factors in Knowledge Work

Facilitating Factors

Bloom (2000, pp. 42-44) identifies the following five elements as causing a group to be intelligent (a "collective learning machine"):

1. **Conformity enforcers:** Mechanisms that cause consensus and similarities among most members of the group.
2. **Variety generators:** Mechanisms that cause some differences and discussion among members of the group.
3. **Inner judges:** Mechanisms that cause individual members of a group to reward themselves for successes and to punish themselves for failures, and cause everyone to evaluate a concept or idea, and validate it after their own experience-based verification.
4. **Resource shifters:** Mechanisms that shift resources (e.g., admiration, information, data, concepts, knowledge, money, or influence) to members of the group.
5. **Intergroup tournaments:** Competitions between subgroups or departments (such as games, corporate competitions, rivalry discussions, etc.)

Other authors, like Surowiecki (2005), say that there are three conditions for a group to be intelligent (for a "crowd to be wise"):

1. **Diversity:** The group includes members with a wide diversity of knowledge or abilities (and the ability to recognize successful and unsuccessful outcomes).
2. **Independence:** Group members use their own knowledge and abilities without being overly influenced by others. (When group members have too much influence over each other, various kinds of bad outcomes can result. See inhibitory factors section below.)
3. **A particular kind of decentralization:** Group members' actions are *aggregated* in a way that finds the right balance between: (a) "making individual knowledge globally and collectively useful," and (b) "still allowing it to remain resolutely specific and local."

Inhibitory Factors

Finally, there are several general factors that can inhibit collective intelligence, such as groupthink and informational cascades, social dilemmas, coordination failures, or failures in thinking itself (Malone, Jay, Legay, & Kosorukoff, 2006).

The first barrier to collective intelligence is called groupthink and social conformity, which was described by Janis (it is perhaps the best explored factor) and developed further in numerous experimental studies. The key point of this research is that people's tendencies to conform, imitate, and avoid conflict can reduce the effective diversity of opinions, and lead to judgments and decisions that are inaccurate, premature, systematically biased, and so forth. The analogue to this phenomenon in pragmatic distributed collective intelligence, as James Surowiecki points out in *The Wisdom of Crowds*, is the informational cascade, where imitation produces fads and conformity instead of individual decision making. In other words, the knowledge of the whole turns out to be less than the sum of the parts, because ***only some parts are actually contributing while everyone else conforms or imitates.*** For this reason, mechanisms that foster diversity and independence might improve collective intelligence. At the interpersonal level, this means practices and norms surrounding respect for individual ideas and contributions (as in the early stages of a brainstorming session). At a distributed level, this results in structural barriers in the physical, legal, or IT "code" (e.g., the walls around a voting booth).

An excellent example based on heuristic experiments of how early decisions by some group members can unduly bias the decisions of later group members is the study of online music ratings by Salganik, Dodds, and Watts. Here is a summary of that study from its online abstract:

Hit songs, books, and movies are many times more successful than average, suggesting that 'the best' alternatives are qualitatively different from 'the rest'; yet experts routinely fail to predict which products will succeed. We investigated this paradox experimentally, by creating an artificial 'music market' in which 14,341 participants downloaded previously unknown songs either with or without knowledge of previous participants' choices. Increasing the strength of social influence increased both inequality and unpredictability of success. Success was also only partly determined by quality: the best songs rarely did poorly, and the worst rarely did well, but any other result was possible. (Salganik, Dodds, & Duncan, 2006)

A second category of barriers includes prisoners' dilemmas, social loafing, and tragedies of the commons (Davenport & Prusak, 2000). These dilemmas or barriers, which involve disincentives for collective performance, are less explored, and described in less depth in economics. They apply at both the interpersonal level (e.g., social loafing in teams) and at the distributed level (low voter participation in democracies). The knowledge and intelligence of the whole turns out to be less than the sum of the parts because ***some parts contribute but others slack off.*** This tells us that it would be important to consider carefully structured incentives to reward individual participation as well as collective intelligence. This naturally occurs in futures markets and betting, but further application and innovation on such ideas is possible.

While the first two barriers involve mechanisms that suppress or delete individual contribution, a third category involves failures to integrate contributions when they are made adequately. Surowiecki offers the traffic jam as a simple example. Information overload on the Internet is another. The knowledge and intelligence of the whole turns out to be less than the sum of the parts because ***the parts' contributions interfere with or cancel each other***. Solving this problem chiefly involves evolving structures and practices that coordinate individual and group contribution. At a distributed level, structures are highly visible, albeit incompletely studied. For example, there are congestion pricing for traffic systems, eBay's auction and interpersonal rating system, Amazon.com's collaborative filtering, Google's algorithm for search ranking, Wikipedia's review practices (as studied by Giles [2005, pp. 900-901]), and so forth. There is similar wealth on the interpersonal side, although many of the practices remain proprietary or tacitly in the hands of professional facilitators.

A final category of barriers to collective intelligence and innovation emerges from William Isaacs' work on dialogue. His theories build upon work by physicist David Bohm on "thought as a system," a new perspective in which all thinking and intelligence is understood to be collective. Within the system of collective thinking, Isaacs identifies four key pathologies that decrease collective intelligence. For each of pathology, he describes a principle that should be kept in mind and a dialogue practice for individuals to refine their own awareness and intelligence quality and contribute to fostering collective intelligence (Malone et al., 2006):

- **Abstraction/Fragmentation:** The tendency to hold oneself distant or separate from the world, for example, by abstracting or compartmentalizing it.
  - Siloing is a clear symptom of this kind of phenomenon: "That's an economics problem, not a psychology problem"; "That's a marketing problem, not a manufacturing problem"; "Not invented here."
  - Staying high on the so-called "ladder of inference" (Argyris, 1998), that is, arguing at the level of fragmented and reified ideas instead of about the flow of experience and data.
  - An example of this issue is: "This is a unique case" instead of "this is a symptom of how the whole thing is working."
  - Antidote: Listening (to data, to people, to the innovation emergence); that is, the principle of *holographic participation*, which is all things are whole, connected.
- **Idolatry of Memory:** The repetition of automatic answers, routines, stereotypes, and behavior patterns from memory.
  - "We solved that problem years ago"; "That's just the way we've always done things around here"; "We have a human resources department, therefore we're taking care of our people."
  - Antidote: Voicing what is actually new and emergent in one's understanding and experience; that is, the principle of *unfolding potential*, which is, the universe is always unfolding and producing the new.
- **Certainty:** The "knowledge" that one's view (often a manager or chief officer) is correct.
  - "That's impossible"; "There's no way that could be true."
  - Antidote: *Suspending* one's assumptions and prejudices for personal and collective reflection, that is, the principle of *proprioceptive awareness*, which is learning to see and feel how your assumptions are affecting your thinking and actions.
- **Violence:** The repression, disrespect, and destruction of alternative points of view in order to force acceptance or consensus of one's own understanding.
  - "No educated person could take that view"; "You're an idiot for believing that"; "That's all well and good, but…"
  - Antidote: Respecting diversity of opinion, style, and knowledge; that is, the principle of dif*ferentiation*, which is, diversity is natural and valuable, and collective intelligence means fostering differentiation and integration.

Enterprise 2.0 ground rules are related to these strong and weak factors of collaborative intelligence (Davenport & Prusak, 1997) and tackle each one of them to adequately emerge social capital.

SOLUTIONS AND RECOMMENDATIONS TO FOSTER COLLABORATION AND KNOWLEDGE EMERGENCY THROUGH ENTERPRISE 2.0 IDEAS

Enterprise 2.0 Key Technologies and Models for Improving Knowledge Work

As mentioned above, Web 2.0 and its application in enterprises can be seen as the computer industry's business revolution caused by the move to the Internet as a platform, and an attempt to understand the rules for success on that new platform. The key rule is to build applications that harness network effects to improve as they are used by more and more people.

The concept of Web-as-participation-platform captures many of these characteristics from the viewpoint of the new software as a service (SaaS) paradigm. Bart Decrem, founder and former CEO of Flock, calls Web 2.0 the "participatory Web" and regards Web-as-information-source as Web 1.0 (O'Reilly, 2004).

The following sections deal with the different existing Enterprise 2.0 technologies from two different viewpoints: first, a service-oriented perspective that is paving the way for a user-centered Web of services, recently termed as global SOA (Schroth & Christ, 2007); and second, a user-centered content driven perspective, comprising enterprise blogs, wikis, RSS, and other business knowledge channels.

Service-Oriented Enterprise 2.0 Technologies

The number of enterprises that are bringing their business systems to the Web to automate cross-organizational business transactions is constantly growing. Porter (2001) says that benefits of performing such transactions electronically include extending market reach, saving time, cutting costs, and responding to customer queries more agilely. Renowned scientists such as Malone (2001) cite the relentless march of improvements in the cost-performance ratio of information technology as the main driver of this development. SOAs have attracted, as McAfee (2005) notes, a lot of interest during the last few years as they are expected to play a key role as enablers of seamless application-to-application integration, both within company boundaries and on a global, cross-organizational scale, required to build this scenario.

From a technological viewpoint, Web services (Alonso, Casati, Kuno & Machiraju, 2004) have been massively adopted as the technical foundation for the realization of SOAs. Even so, Web Ssrvices-based SOAs mostly only exist within company boundaries at present (Roman et al., 2005, pp. 77-106). The global provision and consumption of services over the Internet is still at an early stage and has not yet taken on a significant role in realizing cross-organizational collaboration in an *Internet of services.*

Several reasons, such as high technical complexity, implementation and maintenance costs, inflexibility, and the lack of widely accepted standards for defining service choreographies as well as message semantics, have been repeatedly identified as key factors that have prevented the emergence of a global mesh of interoperable Web services, as Hinchcliffe says (2007). Further hurdles on the path to a "global SOA" include the lack of global-scale service discovery, as well as platforms allowing for intuitive human-guided service interaction and composition. Recently, the emergence of the Web 2.0 phenomenon is expected to act as a facilitator of such a global SOA (McAfee, 2007). Novel Web 2.0 technologies and design principles are now about to experience increasing acceptance as they allow for reusing, customizing, interconnecting, composing, and finally exposing Web-based content or functionality again as new resources. They are, therefore, considered not as a substitute for, but as an enrichment of, SOA concepts and technologies (Schroth & Christ, 2007; Schroth & Janner, 2007).

User-Centered Global Service Oriented Architectures (Global SOA)

A number of Enterprise 2.0 collaboration platforms are beginning to proliferate. By leveraging desirable Web 2.0 attributes, these platforms provide enterprises with an ecosystem of employees, partners, suppliers, and customers who collaborate to develop capabilities by collectively generating, sharing, and refining business knowledge. Nevertheless, enterprise collaboration should evolve towards a new paradigm in which knowledge workers are considered as coproducers not only of information, but also of software services and applications that promote specific competitive advantages and/or meet their immediate needs, without involving IT departments. The Web 2.0-based approach to a global SOA empowers users to coproduce and share instant applications and thus represents a major step forward to evolving the above ecosystem into one in which all the stakeholders will also be able to collaboratively develop capabilities and innovate operating procedures by remixing and integrating already available services through the emerging ideas of Enterprise 2.0 mash-ups ("Mashing the Web," 2005).

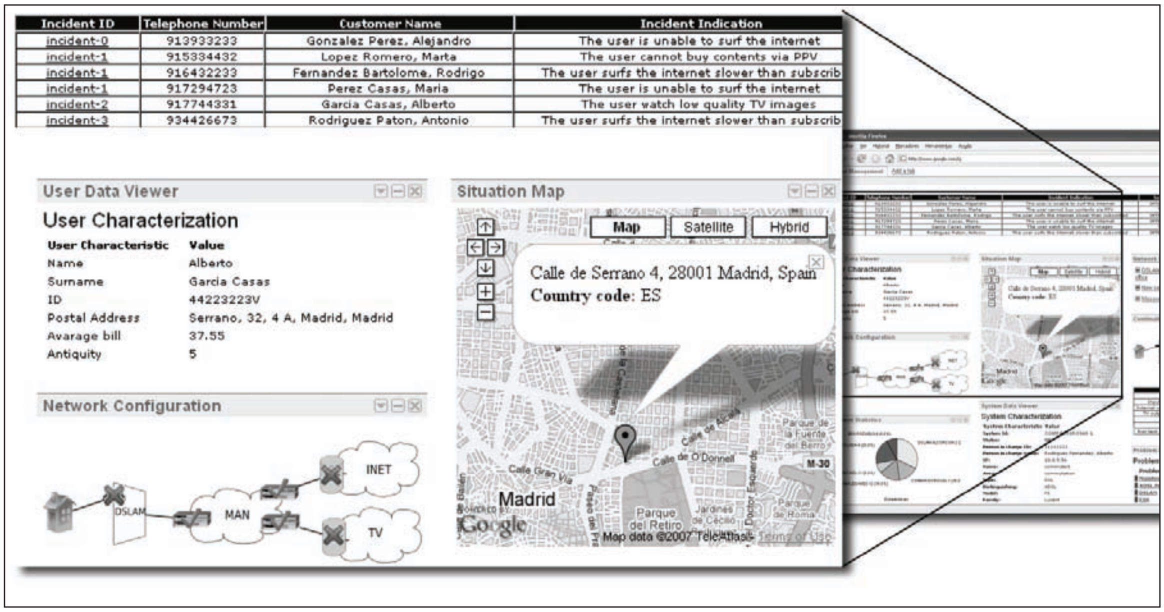
Enterprise 2.0 Mash-Ups

Content-driven mash-up-oriented programming (a.k.a. situational programming or instant programming) (Smith, 2006) is a new agile application development paradigm[1] in which knowledge workers, who do not have previous coding skills but do have extensive domain expertise, visually assemble and combine off-the-shelf gadgets (a.k.a. widgets), that is, discrete self-contained domain data-oriented components, with both development (service and data binding and interconnection) and runtime rendering capabilities. These gadgets represent the basic building blocks for knowledge workers to assemble new services (e.g., SOAP or REST-based lightweight Web services), data sources (e.g., Atom/RSS feeds) and other gadgets, and to render them as necessary to develop the application they need in a very short time. The kind of hybrid application that results from applying this new paradigm is often called enterprise mash-up (a.k.a. situational application or instant application) (Hof, 2005).

A simple example would be a mash-up connecting three gadgets: a list of tasks involving customers, an agenda of customers, and a Google map. By attaching the three to each other, the agenda gadget will display the customer's details and the Google map gadget will display the customer's address on a map as you scroll the task list. This would be useful, for example, for an employee responsible for the task of geographically locating the customer. It is the knowledge worker who can develop this "service," and do it on the fly with the help of mash-up enablers. This way a business person could build a "dashboard" to see how weather is affecting sales at retail outlets. By aggregating information from public Web sites, such as mapping and weather services, the business person could assemble a very useful, albeit simple, content-driven application. Companies are trying to capitalize on these technologies (Smith, 2006) with software and services for relatively short-lived, quick-to-build applications.

Figure 1 depicts a real scenario extracted from a Telefónica-based mash-up which connects four gadgets: a list of tasks involving customer requests, a customer agenda, a Google map, and a network status map. Figure 1 shows how Telefónica's operational support systems' (OSS) knowledge workers create a fully functional environment on their own by visually attaching these gadgets to each other and to the enterprise backend; the agenda gadget will display customer details and have a customer/task selection option, the network map will represent the selected customer's network status, and the Google map gadget will display the selected customer's address on a map when a given task is selected from the list. This

Figure 1. Creation of an EzWeb platform-based enterprise mash-up



enterprise mash-up environment is useful for a user responsible for the task of testing the status of all systems used by a customer. In the event of a problem in the customer's local telecommunications infrastructure, customer geographical location is a big help for the technician to prepare the visit to the customer's home.

As mentioned above, traditional Web services are provided as functionality described by arbitrary (mostly WSDL compliant) interfaces that define input and output messages, as well as the supported service functions. These interfaces are not human-readable and do not facilitate the interaction of users with the underlying services. In the mash-up context resources no longer target technical experts in the corporate context but now go for the huge number of individuals (Anderson, 2006), of Internet users who require intuitive visual means for retrieving resources on the Web and for capturing their respective functionality.

This way, the Web 2.0-based approach to a global SOA delivers a mash-up-enabled infrastructure to help businesses share and collaborate with the business ecosystem and partners instantly. In doing so, enterprise collaboration architectures introduce the mash-up-oriented lightweight programming model as a means for knowledge workers to collaborate in solving an immediate, specific business problem by blending externalities with private business content and services.

The way services are discovered, used, and managed by knowledge workers is fundamental in terms of both the ICT technology and the cultural aspects involved in implementing this enterprise collaboration paradigm shift (Salganik et al. 2006, pp. 854-856). In this respect, user-service interaction must embrace a number of principles to ensure the widest acceptance by knowledge workers. The most important that have been identified are:

1. *Knowledge workers must feel fully empowered* and able to serve themselves from available resources that provide them with access to the content and services they can use to set up their own personalized operating environment in a highly flexible and dynamic way.

2. *Active user participation must be enabled*. Knowledge workers must be able to contribute new and improved versions of resources, as well as share further knowledge about these resources, their use, and their interrelationships.
3. *Community-based collaborations need to be fostered*. The introduction of a *share, reuse, and assembly culture of collaboration* will boost and speed up this process thanks to the network effect.

To exploit this approach to the maximum, IT departments will need to embrace the SaaS model as an effective software-delivery mechanism. This will change the department's focus from deploying and supporting applications to managing the services that those applications provide. Knowledge workers will now extend and improve these services in a collaborative fashion to exploit their extensive domain expertise and their thorough business knowledge.

Enterprise Mash-ups as a Means to Drastically Improve Time-to-Market

Internet technologies continue enabling businesses to expand their ecosystems and partnerships. This expansion process means, on the one hand, that the information technology effort focuses on work items related to integration, usually requiring a minimum of 6 months per request. On the other hand, partnerships change, and some business collaborations last less than 12 months. Consequently, there is a whole bunch of applications not being written today because they are not affordable due to time-to-market constraints and/or because there is no justification for IT investment. Knowledge workers' needs are typically of short duration (ranging from one week to several months), thereby limiting justification for IT investment too. It would be sufficient if they were provided with informal, just-in-time access to domain content, and were able to create their own short-lived ad hoc application for each individual need, without the need for IT investment.

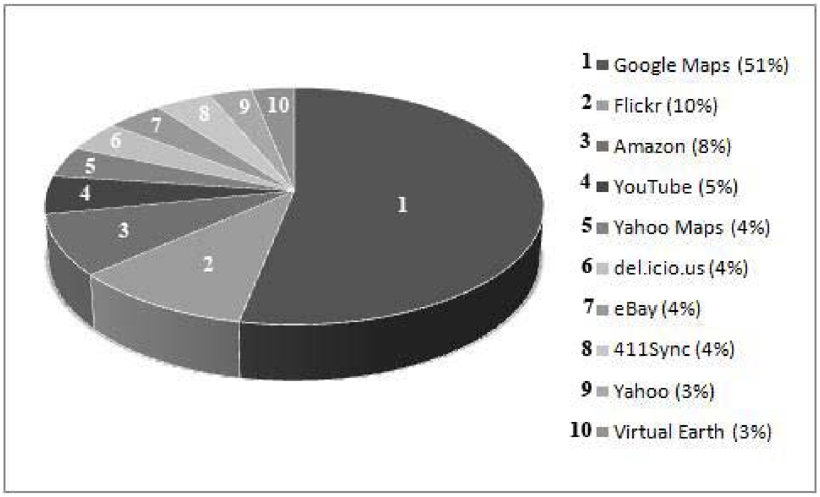
Enterprise 2.0 mash-ups, and the associated application development paradigm, clearly fulfill these needs. Mash-ups will help businesses share and collaborate with the business ecosystem and partners instantly. This in turn will help evolving enterprise collaboration towards a new paradigm in which knowledge workers (without previous programming skills, but with thorough business knowledge) are considered as coproducers not only of information, but also of software services and applications that promote specific competitive advantages and/or meet their immediate needs, without involving IT departments, and share the solution with the remainder of the organization. This will lead at last to an ecosystem of knowledge workers collaborating to develop capabilities and innovate operating procedures by remixing and integrating available services, exploiting the collaborative intelligence. Community-based collaborations could speed up this process thanks to the network effect caused by broader community support and participation (architecture by participation). Additionally, the introduction of a reuse and assembly culture will boost this process, allowing strong business value synergy and linkages.

Current Impact of Enterprise 2.0 Mash-Up Technology

The ProgrammableWeb.com Web site acts as a major aggregator of numerous (currently over 1,600) references of assorted mash-ups existing all over the world. It provides statistics about used resources, a classification of mash-ups by categories, as well as user statistics to evaluate mash-up popularity. Therefore, it serves as a central source of empirical data to work with. Several facts can be inferred from these data:

- First, large companies such as Google, Amazon, and Microsoft started to successfully provide Web-based resources that were

Figure 2. Chart of most popular mash-up resource providers (according to ProgrammableWeb.com)



leveraged by numerous users to create mash-ups. At least 836 Web-based applications have already integrated the "Google Maps," a resource that offers geographical data.

- Second, there is a shift away from the professional corporate context towards a private, end-user driven field of applications. As opposed to the focus of traditional Web services, the resources used for building mash-ups target the long tail of Internet users and deal with media management, shopping functionality, entertainment, or desktop applications. Heavy-weight enterprise applications for automating business transactions can only rarely be found in this context.
- Third, besides the SOAP protocol, which is also used in the context of traditional Web services, "light-weight" protocols, like REST (Fielding, 2000) and RSS, are widely leveraged to allow for fast and seamless mashing of different resources.

Summing up, the Web can increasingly be considered as a comprehensive and global development platform containing numerous easily usable and mashable resources that are provided by large firms, as well as by SME and even individual end-users. As argued above, the provision of resources that use lightweight protocols based on uniform interfaces, such as REST or RSS, and also the focus on end-user requirements rather than business-to-business relationships represent core success factors for this new global SOA consisting of numerous mash-ups. Figure 2 shows the current most popular providers of resources leveraged for the creation of mash-ups.

User-Contributed Content-Driven Enterprise 2.0 Technologies

Of the existing categories of Enterprise 2.0 technologies now available, technologies for content management (enterprise *wiki*/*blogs*), contract management, project management, enterprise mash-up platforms, messaging and e-mail, signaling (feeds), listing services, social network analysis and analytics, social search, media, collaborative categorization (a.k.a. *folksonomy*), online Web storage, supporting infrastructure, organizing, social networking, consumer or workgroup *wikis*, massive collaboration, and business process management are worth mentioning (Reding, 2006). There will be significant differences in companies' abilities to exploit these technologies due to the challenges they bring with them.

Because of the opportunities these technologies offer, these differences will matter a great deal. It is important to get an understanding of their real potential and drawbacks, as well as how to take advantage of them holistically.

Andrew McAfee (2006, pp. 21-28) first introduced the acronym SLATES to indicate the six components of Enterprise 2.0 technologies: **s**earch, **l**inks, **a**uthoring, **t**ags, **e**xtensions, and **s**ignals (SLATES). As technologists build Enterprise 2.0 technologies that incorporate the SLATES components, they seem to be following two intelligent ground rules following McAfee's vision of SLATES. First, they are making sure their offerings are easy to use. Second, Enterprise 2.0 technologists are trying hard not to impose any preconceived notions on users about how work should proceed or how output should be categorized or structured. Instead, they are building tools that enable these aspects of knowledge work to emerge. In the following sections we elaborate on the key Enterprise 2.0 technologies that will help a business to successfully exploit every SLATES component.

Enterprise Blogging

Blogging allows users to keep track of ideas and their authors, including concept redefinitions or business process information on a time line in a Web page, as if it were traditional Web content information. This information evolves like an approximating definition cycle based on dialogue and creative discussion, looking around for near ideas and issues to express enterprise knowledge.

There are several social networking functions in enterprise blogging that show the difference between simple blogging systems and systems used for triggering network effects across an organization. Some interesting insights about internal blogging in the *Enterprise Blogging in Practice* case study follow (Rand, 2004).

Michael Cot notes, *"At the department level, I wouldn't say that blogs have been a wide-reaching, raging success, primarily because people don't post to them as much as you'd hope. However, for the people who do post to and read the blogs, they've been very successful"* (Rand, 2004).

Among many other things, people usually post information at their company about their own stories and experiences, the status of tests, brainstorming-based ideas or issues, customer visit/phone call notes, comments that are only useful to bring attention to or track an employer with a project, requests for ideas or help, and even off-topic posts that can be useful for enforcing social networking relationships.

But the biggest problem is limited search capabilities. Without a Google-like quality search (i.e., near real time and full indexing, page-rank, quick search results, etc.) of the enterprise Intranet, it is very hard to find anything, let alone blog posts on relevant topics. People have been shown to get smarter a lot faster using social networking software (a lot of organizations of all sizes are using this Enterprise 2.0 application to trigger network effects and for innovation fostering). In addition to the enterprise blogging platform, it is interesting to stimulate several social networking system functions in Enterprise blogs (Wacka, 2005):

- Contact list (create informal groups or social networks) to maintain easy contact with community members
- Private messages
- Attach files (.doc, .pdf, .zip) and add tags and notes to them
- Advanced taxonomy with both structured and unstructured (free tagging) support
- Powerful ajax editor
- Tasks (to-do lists) for easy collaboration and project management
- Threaded comments for robust discussions
- Revision control
- Basic polls (advanced polling, surveying, and quizzes are available)
- Profiles
- Advanced search
- News aggregator (read RSS feeds and XML files)

- Syndication (generate RSS feeds and XML docs for content, profiles, tags, categories, etc.)

This way, it would be easier to make content and profiles precise. With structured and unstructured categories, it is easier to find people or content on the "long tail" of a curve (Kline & Burstein, 2005). In addition, it is possible to use tracking of individual profiles and posts to monitor user activity (i.e., to find out what others in the community are reading and writing).

Enterprise blogging should offer a useful way for connecting, creating, and collaborating on project management, help desks, finding and identifying experts (people aggregator), recruiting experts, talent, or ideas or innovation management, open innovation and its visibility, knowledge management, product development, and other off-topic tasks.

This platform would provide a comprehensive online ecosystem, a tightly integrated set of publishing, communication, and networking features that support and enable an online experience like never before. Users could engage, create, and share their content online (publicly or privately) in a multitude of ways to achieve greater performance. This technology will help to discover the purpose (i.e., connecting, creating, and collaborating) of an enterprise community in order to improve the company's business strategy. Knowing the purpose determines how the system is configured, how it flows, and how well it succeeds, and therefore the best strategy to carry out.

The following are some tips from Dion Hinchcliffe's (2007) "Nine Ideas for IT Managers Considering Enterprise 2.0," which are easily adaptable to enterprise blogging:

1. It is about ease-of-use, first and foremost.
2. Change requires motivation. Provide it.
3. Emergent does not mean a blank slate.
4. Discoverability is not an afterthought, it is the core.
5. It is okay to fear loss of control and misuse.
6. Dynamic, effective advocates are a key enabler.
7. The problems will be with the business culture, not the technology.
8. Triggering an Enterprise 2.0 ecosystem quickly is likely to be an early activity driver.
9. Allow the tools to access enterprise services

Enterprise Wiki: The 2.0 Approach of Content Management Systems (CMS)

A wiki can be defined as a piece of server software that allows users to freely create and edit Web page content using any Web browser. Wiki supports hyperlinks and has a simple text syntax for creating new pages and crosslinks between internal pages. Because it allows "everyday users to create and edit any website page, it is exciting in that it encourages democratic use of the Web and promotes content composition by non-technical users."

There are some fundamental Wiki design principles, but the most important principle that makes wiki different from any other Web site source is that it allows any enterprise readers to edit the page content as they see fit, if they feel the content is insufficient or poorly organized. If you come across any mistakes in the document as you read an information item, or you have more information that you would like to add to the item, just click on "Edit Text" and you, too, can change the content.

Because wiki is mainly designed to promote content composition by nontechnical users, the formatting rules for editing a wiki are fairly simple, and there are no complicated markup languages. Wiki content generally contains a lot of accurate information, because inaccurate information will be very quickly corrected by other readers.

The main idea of not having anyone to control the content in a centralized way, and/or of allowing *anyone* to edit and publish a document real-time is inconceivable for most people.

Therefore, a wiki can be the underlying technological support for creating a common sharing, emergence, and conceptualization of mash-up data, playing a similar role to ontologies in the Semantic Web vision. In fact, wiki software has demonstrated that ***it works well in a small community of like-minded people, like an enterprise community.*** Documents build up very fast as many people contribute small, manageable pieces. Some contribute contents and information, some contribute links, some correct grammar, while others fix the structure and formatting. Therefore, enterprise wiki allows the input of common descriptions and definitions of key business concepts, that is, everyone in the company can find a resource, bring experience to bear to evaluate and improve the resource. Wiki contents and data follow an iterative lifecycle, and their description undergoes constant improvements, refinements, and evolution.

There are several applications defined as enterprise wiki enablers, like Confluence, Social Text, or Twiki (*InfoWorld* proclaimed 2004 to be the "Year of the Enterprise Wiki"). Heightened interest comes in response to the increasing number of organizations like Google, Nokia, and Yahoo! who are turning to wikis as a way to improve internal efficiency.

Wikis and Content Management

Wikis fall conceptually under the broad concept of content management systems, and users could certainly use the existing CMS to create a *wiki-like* site. However, wikis have unique characteristics that differentiate them from traditional CMS (Choate, 2006).

Wikis emphasize ease of content creation. This simplicity has many sources: a wiki markup language that provides a short-hand way of linking documents and formatting text; the ability of users to edit and create pages independently and directly; a bottom-up approach to site navigation and structure; a very simple templating framework; and, finally, a conscious decision to eschew workflow or even simple approval steps.

Content Creation and Editing

Wiki software focuses on the empowerment of users to create and edit their own pages, but content management systems provide tools for creating and editing content, too. The difference is in their approach. When wikis first came out in 1995, there were not a lot of options for WYSIWYG editing from within a browser, so the wiki markup language (sometimes called "wikitext") provided a particularly valuable short-hand for formatting text that was much easier to learn than pure HTML (Heigl, Glaser, & Anja, 2006).

A good CMS will offer a WYSIWYG interface that makes writing content for the Web, like using a word processor. More wikis nowadays have WYSIWYG editing features, so the wiki markup language is a less interesting feature in terms of formatting, although it does provide the benefit of being supported by all browsers on all platforms, something that is not usually the case with rich-text editors. Many wikis support both wikitext and rich-text editors.

However, there is one area where wikitext still retains its power: linking resources and knowledge. Wiki software still provides a much easier way to link pages within the wiki to each other. Links are made based on the title of a page, so the author does not need to use, remember, or type long URLs in order to link one page to another.

Site Structure and Navigation

Contributors can create new knowledge, pages, contents, and can easily link one page and data to another (Venners, 2003); wikis offer a new unique approach to navigation and site structure.

Traditional information systems usually take a more formal approach to site structure and navigation through enterprise knowledge, with the site organized into a hierarchy by an information architect. User-created pages in a wiki mean that the hierarchy and structure of the site is created in an ad hoc way. Navigation tends to be simple, and the hierarchies are flat. For example, the Wikipedia online encyclopedia has hundreds of thousands of articles on a broad range of topics, but these topics are not arranged in any conceptual hierarchy. The entry for dogs serves as a good illustration. The URL for the article about dogs is: http://en.wikipedia.org/wiki/Dog

A pug is a kind of dog, and the URL for the pug entry is: http://en.wikipedia.org/wiki/Pug

Since a pug is a kind of dog, you might expect to see the following URL for pugs: http://en.wikipedia.org/wiki/Dog/Pug

But it is not there. Several wiki software solutions support more complex content categorization, but many are totally flat, like Wikipedia. Even if the software supports subconcepts, contributors are still allowed to create subpages in an ad hoc fashion and there is no systematic approach to the architecture of enterprise knowledge.

Content Repository and APIs

An experienced architect or administrator will ask of any content technology what the repository looks like. This is a good approach, because they are concerned about back-up, compatibility, performance, and a raft of similar issues.

Wikis have traditionally taken a very simple approach to information storage. Original wikis stored content in plain text files written with a wiki markup language. When a reader requested a page, the page was rendered. This was not speedy, but it worked. These days, wiki packages employ one of several different back-ends, with many housing their content in databases.

A transcendental consideration is whether the software supports automatic back-ups (commercial wiki applications often do). Another thing to think about is what this means in terms of integrating wiki content with content managed by other systems. For example, should an enterprise search system be able to index wiki content, and should the indexed content be raw wikitext, or rendered HTML pages?

This question leads on to the issue of wiki APIs, which, in fact, very few wikis have.

Templates

When a wikitext page is required, it is rendered as HTML in a two-part process. First, the wiki markup is converted to HTML, and links are created between pages. Then, this content is wrapped by a template that provides a consistent look to all the pages in the wiki.

Comparing wikis to a CMS, most wikis have template systems that are very simple, often only enabling one general template for the entire site. Wiki templates (and page rendering in general) are often not cached, so the page is rendered with each request. From an enterprise perspective, a lack of caching can obviously limit system scalability. On the other hand, there is no finicky caching mechanism to deal with.

Workflow

Wiki software completely changes the main idea of a workflow. Wikis are decentralized and typically lack the controlling mechanism of a workflow system with a formal approval process. Wikis workflow systems often lack sophisticated and disaggregated and approval processes is commonly considered a feature and not a fault of wikis. This is contrary to the basic idea of many CMS, which prioritize control over empowerment. Despite this decentralized approach, there is one important thing to remember: the main idea that anyone can edit content is only a general policy and not an inherent characteristic of wiki software.

Control vs. Flexibility

There is a traditional trade-off between control and flexibility in information systems software. Decision-making is centralized by some sort of editor that verifies and approves content prior to publishing in a traditional CMS. With a wiki, the writer writes then publishes without editorial oversight or approval. This direct channel to publication is what makes wikis so wonderful in scenarios that emphasize speed and flexibility.

An important issue to deal with is what possibilities there are if enterprises want to exercise at least some control. In the absence of workflow controls, content creation in a wiki is managed through change monitoring, automated spam prevention, and user access control. Let us look at each one in turn.

Change Monitoring

One simple defense mechanism is to monitor changes in the wiki and enable the rolling back to a previous version through versions control.

Recent changes can be monitored as follows:

- Most wikis have a "Recent Changes" page that lists all the pages that have been changed.
- E-mail notification of changes or support for RSS syndication.
- If more than one person has been tasked with monitoring changes, some wikis offer the capability to track whether a recently changed page has been checked yet, reducing the chances of the work being done twice.
- More sophisticated systems identify and differentiate "trivial" changes from more substantive ones.

In addition to the above ideas, it is important to consider that people make mistakes and sometimes deliberately do things badly. Therefore, the ability to roll back changes is a necessity. Features to look for include capabilities similar to what you would find in a CMS, like the ability to roll back changes to the previous version, to compare different versions side-by-side or the use of diffs between versions so that specific differences between them can be easily identified.

Spam Prevention

Another approach is to monitor the content of changes programmatically, that is, to manage spam prevention. This differs from user access control in the sense that it monitors wiki edits based on the content itself, or patterns of user behavior. Some systems can block access to IP addresses and URLs, or they can block the posting of individual changes based on restricting the use of certain words or phrases, using word lists or regular expressions, and blocking access based on excessive activity.

User Access Control

Enterprise wiki usually means that it has user access control. An increasing number of wiki projects offer sophisticated **more granular level** in user access control issues. Users and groups can be assigned rights to tasks such as reading, editing, writing to, and rolling back a resource to a previous version. There is a lot of variance among wiki packages in terms of how those rights are applied to the site. A less common but useful feature is the ability to restrict access to parts of resources. The most sophisticated enterprise wikis work with single sign-on security systems like Siteminder, or offer network and directory integration (e.g., LDAP and Active Directory) for user authentication and authorization.

Contrary to their reputation, wikis are CMS that can be managed efficiently. They simply take a different approach to content management by choosing to emphasize speed and flexibility rather than strict controls. In order to successfully implement a wiki software package you will need to look at workflow from a different perspective and be sure to select wiki software that provides the right level of content monitoring and access control for your organization.

Enterprise RSS

RSS is a family of Web feed formats used to publish frequently updated digital content, such as blogs, news feeds, or podcasts.

End-users that receive data from this technological channel use programs called feed "readers" or "aggregators", as follows. The user "subscribes" to a feed by supplying to their reader a link to the feed; the reader can then check the user's subscribed feeds to see if any of those feeds have new content since the last time it checked, and if so, retrieve that content and present it to the user.

The initials "RSS" are variously used to refer to the following standards:

- Really Simple Syndication (RSS 2.0)
- Rich Site Summary (RSS 0.91, RSS 1.0)
- RDF Site Summary (RSS 0.9 and 1.0)

RSS formats are specified in XML (a generic specification for data formats). RSS delivers its information as an XML file called an "RSS feed," "Webfeed," "RSS stream," or "RSS channel."

Essentially, Web 2.0 is fully centralized in its conception. Why are skype, del.icio.us, or Flickr Web sites instead of protocols (as foaf is)? The reuse of Web 2.0 data is limited only to the hostside and only with the help of feeds are data able to break out from centralized sites (Hammond, Hannay, & Lund, 2004, pp. 1082-9873). Therefore, feeds and RSS are the key to a new data-distributed model in the Web 2.0, where data are disaggregated on the Internet, and RSS allows data, information ,and remote events to be distributed to end-users through the Internet.

Content Tagging

Content tagging is a growing Internet trend that empowers users to add their own contextual tags to Web content, information, or resources. Typically, as Gruber (2005) affirms, this results in excellent content categorization in a way that is relevant to the needs of users.

Tags are, therefore, Web page and/or database descriptors (e.g., title, author, language, date, subject) that are assigned to knowledge (e.g., information, Web content, distributed resource, etc.). One of their main purposes is to help people find information. Tags can be assigned to document descriptions (e.g., card catalog cards in a library) or they can be assigned to the documents themselves or both.

Tags can be assigned by document authors, information professionals, editorial assistants, or even by computer programs. Artificial intelligence programs are a fast and easy (but not always the most accurate) method of tagging. Information professionals can produce highly accurate and effective tags that take into account all the nuances of language and subject matter, but there is a limited supply of people with these skills.

These tags are useful for creating an emerging user-centric categorization of content in a folksonomy (a user-generated taxonomy used to categorize and retrieve Web content). Folksonomic tagging is intended to make a body of information that is increasingly easy to search, discover, and navigate over time. A well-developed folksonomy is ideally accessible as a shared vocabulary that is both originated by, and familiar to, its primary users. Two widely cited examples of Web sites using folksonomic tagging are Flickr and del.icio.us.

Folksonomies are developed in Internet-mediated social environments. Therefore, knowledge workers can discover who has created a given tag for a concept, and see the other tags that this person created. In this way, folksonomy users often discover the tag sets of another user who tends to interpret and tag content in a way that makes sense to them. The result is often an immediate and rewarding gain in the user's capacity to find related content. Part of the appeal of folksonomy is its inherent subversiveness: when faced with the choice of the search tools that Web sites provide, folksonomies can be seen as a rejection of the search engine status quo in favor of tools that are created by the community.

Folksonomy creation and searching tools are not part of the underlying World Wide Web protocols. Basically, these folksonomies arise in Web-based communities where special provisions are made at site level for creating and using tags, as in del.icio.us. These communities are established to enable Web users to label and share user-generated content or to collaboratively label existing content. Since folksonomies are user-generated and therefore inexpensive to implement, advocates of folksonomy believe that it provides a useful low-cost alternative to more traditional, institutionally supported taxonomies or controlled vocabularies like enterprise IT solutions. An employee-generated folksonomy could therefore be seen as an "emergent enterprise taxonomy." Some folksonomy advocates believe that it is useful for facilitating workplace democracy and the distribution of management tasks among people actually doing the work.

As many authors note in blogs and articles, "workplace democracy is also seen as a utopian concept at odds with governing enterprise reality, the majority of which exist and thrive as hierarchically-structured corporations not especially aligned to democratically informed governance and decision-making." Also, the folksonomy may facilitate workflow, but it does not guarantee that the information worker will tag and, then, tag consistently, in an unbiased way, and without intentional malice directed at the enterprise.

Strategic Sensemaking

The increased importance of sensemaking will prove to be one of the central drivers for Enterprise 2.0 technologies adoption. The organizational theorist Karl Weick says that sensemaking is a central task in new organizations. Dan Russell at Creating Passionate Users provides a definition of sensemaking that will serve as a useful starting point: "Sensemaking is in many ways a search for the right organization or the right way to represent what you know about a topic. It's data collection, analysis, organization and performing the task" (Dervin, 1983).

Sensemaking can be a solution for constructing sensible accounts out of ambiguous, ambivalent, equivocal, and conflicting data in organizational settings for managers and leaders in the knowledge organization and management. In a world characterized by significant technology and strategic change, the problem of sensemaking becomes more acute.

One of the attractions of Enterprise 2.0 technologies is that they make business strategies more feasible and scalable. Most of the technologies depicted in this section take participation as far as what face-to-face methods can support. They make it possible to generate and organize more extensive raw materials and inputs to planning/sensemaking processes. Wikis with good version tracking and refactoring capabilities make it both safer and easier to generate and work through alternative representations/sensemakings. Realizing this sensemaking potential will require brokering some introductions and partnerships. Those adept in the techniques are likely not to be versed in the ways that the technologies reduce or eliminate some of the key barriers to successfully using the techniques. Those who understand the technologies may not be aware that the techniques exist, much less that they could benefit from technological improvement. One starting point is to investigate the sensemaking planning techniques and practices and map points where the technologies enable, simplify, or improve the techniques for those promoting Enterprise 2.0 technologies.

Social Networking

Nohria and Eccles (1992) give a common definition of social network as "a social structure made of nodes (which are often organizations or individuals) tied by one or more specific types of relationships, such as values, visions, idea, financial exchange, friends, kinship, dislike, trade, web links, etc."

Social network analysis approach consists of relations in terms of *nodes* and *ties.* Nodes are actors within the networks, and ties are the relations between the actors. There can be many kinds of ties between the nodes. Research in a number of academic fields has shown that social networks operate on many levels, from families up to the level of nations, and play a critical role in determining the way problems are solved, organizations are run, and the degree to which individuals succeed in achieving their goals.

A social network is a map of all of the relevant ties between the nodes being studied. The network can also be used to determine the social capital of individual actors. These concepts are often illustrated by means of a social network diagram, where nodes are the points and ties are the lines. In traditional social network communities, an initial set of founders sends out messages inviting members of their own personal networks to join the site. New members repeat the process, adding to the total number of members and links in the network. Sites then offer features, such as automatic address book updates, viewable profiles, the ability to form new links through "introduction services," and other forms of online social connections. Social networks can also be organized around business connections, as in the case of LinkedIn.

The combination of networking is a new point of view to social networking that combines both off-line elements (face-to-face events) and online elements. The newest social networks on the Internet are becoming more focused on niches such as travel, art, and so forth. Other social networking sites focus on local communities, sharing local business, and entertainment reviews, news, event calendars, and happenings.

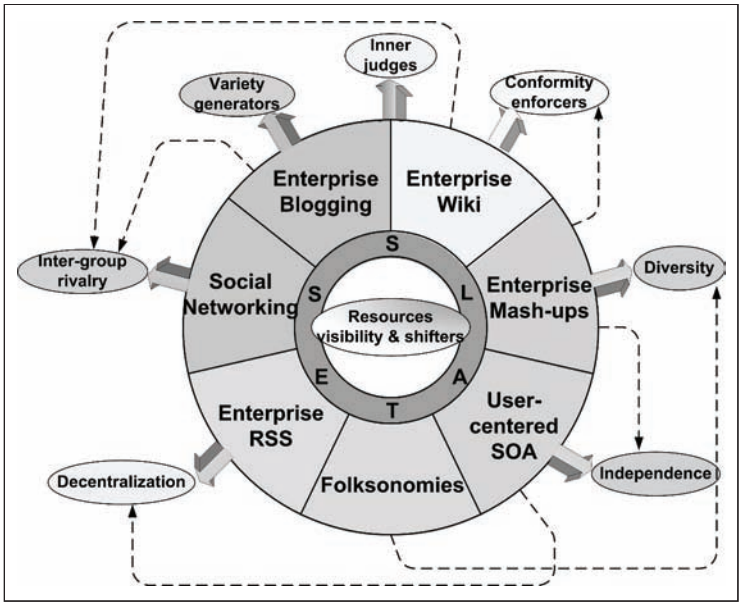
Traditional social networks on the Internet were public, and any user could participate. However, large enterprises and organizations also have access to private social networking applications often called enterprise social networking software. For example, Microsoft released an enterprise social networking application in the form of a free add-on for Microsoft Office SharePoint Server called Knowledge Network (currently in beta) in February 2007. Organizations install these applications on their own servers and enable employees to share their networks of contacts and relationships to outside people and companies.

Aligning the Business Strategy with Enterprise 2.0 Ground Rules, Diving Forces and Best Practices

Figure 3 shows a subset of the main Enterprise Web 2.0 technologies described throughout this chapter and what innovation promoting factors are fostered by each technology or ideology. Generally, each Enterprise 2.0 approach follows the SLATES principle described by McAfee. In addition, one of the most important innovation factors described in high-level knowledge working, that is, resources and content visibility through the Web and its simple modification and reedition in a shifting of resources is fostered by all technologies in the framework.

- Enterprise Wiki is used to input common descriptions and definitions of main business concepts. Everyone in the company can bring his or her own experience and knowledge to bear to find, evaluate, and improve a content resource. This iterative process enforces common data and knowledge conformity across the enterprise. Each knowledge worker must review the wiki concepts and will use an inner judge of the content to do his or her best to improve the concepts. In addition, this phenomenon shows group and department knowledge outputs, allowing the management of constructive intergroup rivalry in order to improve the descriptions of concepts or knowledge about business processes.
- Enterprise blogging is useful for keeping a track on ideas, concept redefinitions, or business process information on a time line. This visibility stimulates each knowledge worker to discuss this information, generating a variety of ideas in an approximate definition cycle. Obviously, this technology, as the wiki

Figure 3. Enterprise 2.0 technologies: Innovation fostering framework



approach, fosters the ideas of judgment and inter-group rivalry through the contribution of their own experiences. Therefore, wiki and blogging together can tackle the emerging knowledge, social capital, and collective enterprise intelligence created by the groups of knowledge workers.

- The social networking idea promotes the rivalry and communication between enterprise employers in a social net, using several communication channels to increase the dialogue in the enterprise and its departments.
- Enterprise mash-ups deal with the diversity of solutions to a definite problem within the enterprise. Software solutions based on a heterogeneous merge of separate components communicated and parameterized by knowledge workers fosters diversity and originality in the enterprise, eliminating barriers to the innovation bloom. This approach also helps to enforce conformity in the enterprise about systematic knowledge, that is, what mash-up solution is the best to afford a particular solution for a business process. Users follow a "do-it-yourself" ideology that encourages the independence of end-users from the service providers and legacy.
- Global (user-centered) SOA mainly fosters the idea of the independence of end users and end-user innovation from the content and services providers, breaking down traditional innovation barriers in SOA approaches. In addition, it motivates a decentralization of resources across the Web, fostering client-computation and disaggregated data models and composition against the service traditional front-end.
- Enterprise RSS can manage the decentralization of data in Web 2.0 and Enterprise 2.0. Feeds and RSS are the keys of a new data-distributed model where data are disaggregated in Internet, and RSS is useful for distributing data, information, and remote events to end users through the Internet.
- Finally, folksonomies are related to the visibility of resources, and resources discovery and recommendation issues. The use of a

relaxed taxonomy based on tagging by end users improves the diversity of knowledge related to these resources, and the collaborative intelligence present in enterprises can be better emerged.

Table 1 shows how the Enterprise 2.0 technologies are related to the factors that inhibit or slow down innovation.

These relationships are of three types: a technology can be appropriate for deleting a negative factor (shown as ✓), could cause this factor (shown as ✗), or must be applied very carefully because it can cause or delete a factor depending on its use.

Next these specific relationships between technologies and inhibit factors are depicted in more detail:

- An enterprise Wiki is useful for collaboratively editing contents through a Web platform. In this technology, a new content or concept would commonly be inserted to the wiki, imitating the description, structure, and form used in other previous concepts, that is, it leads to a negative conformity and imitation process without concern about enterprise integration. On the other hand, it is very simple to edit a concept or contribute with one's own experience and knowledge to a wiki. Therefore, this idea reduces social loafing and the slack-off caused by traditional complex content management systems. The wiki uses an iterative description of concepts, that is, a new edition overwrites the previous one and could cause coordination failures. Finally, a wiki content is usually anonymous and iteratively improved. For this reason, it is easy to eradicate the idolatry of memory in enterprise knowledge, constantly improving the contents and anyone in the enterprise to properly discuss the manager's ideas.
- Enterprise RSS is a communication channel to manage the decentralization of data in Enterprise 2.0. Therefore, some factors like conformity or slack-off depend on the content transmitted through the feeds. The RSS architecture, based on client aggregators and feed channels, decreases the coordination failures during contents accessing in the enterprise. In addition, this data communication channel, split into several different disperse channels merged in the client, is a correct way to deal with data and their abstraction and fragmentation. The negative part of RSS is that the data origin is known, and this could foster the feeling that data created by heads or managers and distributed by RSS are certain.

Table 1.

	Conformity & imitation	Social loafing & slack off	Coordination failures	Abstraction/ Fragmentat.	Idolatry of memory	Certainty
Enterprise Wiki	✗	✓	✗		✓	✓
Enterprise RSS	?	?	✓	✓		✗
Folksonomy	✓	✓			✓	✓
Enterprise Blogging	✗	✓	✓		✗	✗
Enterprise Mash-ups	✗	✓	✗	✗	✓	✗
Global SOA	✓	✗	✗	✓	✓	
Social Networking	?	?	✓			✗

- Folksonomies can create informal taxonomies based on tags (anonymous or not) in a very simple way using a Web platform. A new concept is very quick to tag. Therefore, this technique decreases the conformity in the conceptualization and the social loafing surrounding tagging contents and applying knowledge. Each knowledge worker will use his or her own experience, refining the tags used, even if these tags have been imposed by managers. For this reason, the knowledge is extrapolated and transformed, and therefore social capital emerges as obsolete enterprise conceptualizations are forgotten.
- Blogging keeps a track of ideas (and their authors), concept redefinitions, or business process information on a time line. This technology often causes a conformity feeling among the personnel, imitating structures, ideas, natural language descriptions, and schemas during a new track of knowledge in other enterprise blogs (in fact, wiki could cause a parallel effect). As with wiki editing, it is so simple, friendly, and quick to edit a new comment, or to refine an idea that social loafing is evidently decreased. However, each contribution is logged and stored in a blog, which has several consequences: coordination failures and overwrite issues are decreased but knowledge workers could be afraid of expressing their ideas in public or of arguing a traditional notion (provoking an idolatry of memory) or a leader's opinion.
- Enterprise mash-ups motivate software solutions based on a heterogeneous merge of separate components. A working mash-up often causes a conformity feeling in knowledge workers. Therefore, it is recommendable to force them to create their own solutions fitted to their own problems. In this same sense, nonprogrammer users should be offered a simple way to create mash-ups and reduce slack-offs. This approach may often cause coordination failures across departments, creating solutions to similar business problems. Likewise, this technique can foster a wrong abstraction level at solving problems, creating partial software solutions without considering the whole problem dimension. This approach can improve previous mash-up-oriented solutions in a very fast and simple way, reducing the traditional idolatry of previous software or enterprise solutions so harmful in business strategies. Finally, it is very dangerous to publish strict mash-up compositions as unique software solutions created by managers or specialized departments, because this could provoke an innovation barrier to new ideas or improvements to these solutions.
- User-centered SOA mainly fosters the idea of independence of end users and end-user innovation from the content and services providers, focusing on reducing conformity and imitation issues caused by the traditional rigid SOA approach. This idea must be applied carefully because it could foster a slack-off in nonprogrammer users that have a poor perspective of Web services, or problems coordinating efforts in pragmatic developments. This issue can be easily improved using this approach and a mash-up orientation together. A strong point of this technique is the correct abstraction/fragmentation view of enterprise complex problems, coordinating or orchestrating user-centered services to tackle with whole problems through interface charts and storyboards linked to concrete workflows. One of the most important ideas is the high parameterization in enterprise services. This makes it easy to forget traditional memorized solutions, improving them in an adaptable way.
- The social networking is a general philosophy focused on improving effort coordination across a social group, fostering collective intelligence emergence and exploitation,

reducing the possible coordination failures, and increasing outsourcing visibility. Like RSS, social networking can be considered a family of communication channels. Therefore, aspects like imitation, conformity, or social loafing depend directly on the content and the management of social information and knowledge. In this philosophy, it is harmful to introduce managers and manager-generated knowledge that can cause the social group concern and delimit its innovation process and evolution.

Application to Other Key Business Web Strategy Areas

This section looks at each of the implications of the explained Enterprise 2.0 vision for communication and information sharing, knowledge management business intelligence and business process management, and its application to key business web strategy evolution.

High-Performance Collaboration and Community-Building

More and more often organizations tend to behave like dynamically reconfigurable networked structures that carry out their tasks through collaboration and teamwork. Effective teamwork is an essential part of any nontrivial engineering process, and collaborative capabilities are an essential support for these teams.

Traditionally, collaboration has been a means for organizations to do their work. As illustrated throughout this chapter, however, the context in which they do this work is changing, especially in regards where the work is done, how the work is organized, and who does the work, and with this the characteristics of collaboration. Work teams face sizeable collaborative challenges, for which they have need of tools that they can use to communicate and coordinate their work efficiently. These challenges have been tackled traditionally by profuse research in *computer supported collaborative work* (CSCW). CSCW has a great deal of drawbacks can be dealt with under the Web 2.0 vision. Web 2.0 has taken a step forward in this respect with the emergence of *social networking* and *communities*, where the emphasis is on *open source communities.*

Open source communities are one of the most successful—and least well understood—examples of high-performance collaboration and community-building on the Internet today. *Open source communities* began as loosely organized, ad hoc communities of contributors from all over the world who shared an interest in meeting a common need. However, the organization of these communities has proven to be very flexible and capable of carrying out all kinds of developments, ranging from minor projects to huge developments. Businesses following the *Enterprise 2.0* vision can benefit enormously by learning what open source communities are and how they work. It is important to remember how the use of the *Enterprise 2.0*-based IT infrastructure will transform today's Intranets into virtual spaces where all project stakeholders, possibly distributed in time and space, can negotiate, brainstorm, discuss, share knowledge and resources, and, generally, work together to carry out some task. The vision presented in previous sections will help to definitively change Tom Allen's well-known "30-meter" rule, stating that two scientists or engineers whose desks are more than 30 meters apart have a communication frequency of almost zero.

Collaborative Knowledge Emergence and Management

The concept of knowledge management introduced previously has been an elusive chimera to corporations since the mid-1990s. Ever since employees came to be seen as knowledge workers, companies have been searching for ways to capture and disseminate the stuff inside their heads. Knowledge management systems have traditionally tried to do this by both relying on distributed production and providing high commonality. This way, they have sought to elicit tacit knowledge, best practices, and relevant experience from people throughout a company and put this information in a widely available database.

Nevertheless, a corporation's knowledge is scattered across a multitude of communication media channels, including e-mail threads of conversation, instant messaging talks, and communication media platforms or Intranets, corporate Web sites, and information portals. Production in the first group is distributed (that is, knowledge workers can create and distribute digital information free of charge), and many of them leave communication traces (e.g., instant messaging talks or e-mail threads of conversation). However, the degree of commonality of this information is low (e.g., only the participants in an e-mail exchange have access to the knowledge held in the thread of conversation). In the second group, commonality is high, but production is centralized and visits to platforms leave no traces. Both the "low commonality" factor in current channels and the "centralized production" and "lack of traces" factors in current platforms imply that most knowledge work practices and output are invisible to most people in most companies. For this reason, it is very important to understand the presented vision and especially how *Enterprise 2.0*-based IT introduces new channels and platforms that enable distributed production, communication tracing, and high commonality of information and services simultaneously to improve user productivity in the way explained in the framework of Enterprises 2.0 technologies and their application to innovation, knowledge emergence, and content visibility.

On the other hand, current knowledge-work-specific technologies, like highly structured knowledge management systems using complex taxonomies and/or ontologies are not doing a good job at capturing, sharing, and applying their knowledge, which is typically highly unstructured and textual. In this respect, a recent study (Morris, 2005) has shown that only 44% of respondents agreed that it was easy to find what they were looking for on their Intranet. The channels and platforms in traditional use are not much good at providing answers to questions like who is working on a similar problem right now. Or what is the right way to approach this analysis? The presented practical Enterprise 2.0-based collaborative (and social) approach can catalog and search knowledge so that employees can easily leverage it throughout the firm. Briefly, the application of the broad spectrum of Enterprise 2.0 of technologies to business Web strategy should be considered.

Finally, most current platforms, such as knowledge management systems, information portals, Intranets, business process management (BPM), business activity monitoring (BAM), and workflow applications are highly structured from the start, and users have little opportunity to influence their structure or to customize their functionality and their interfaces. Emerging platforms, like wiki, blogging, or folksonomies (explained throughout this chapter), for generating, sharing, and refining information under the Enterprise 2.0 vision umbrella focus not on capturing actual knowledge, but rather on knowledge workers' practices and output.

In conclusion, the Enterprise 2.0 vision is significant in this respect because it can potentially knit together an enterprise and facilitate knowledge work in ways that were out of the question before. Putting it simply, Enterprise 2.0 technologies have the potential to make the knowledge management infrastructure of a corporation what the Internet already is, that is, an online platform with a constantly changing, searchable structure built by distributed, autonomous, and largely self-interested peers. Technologies like blogs, wikis, and labeling systems capable of emerging folksonomies make a decisive contribution to the elicitation of knowledge, best practices, and relevant experience that is scattered across the corporation and make this information trustworthy, searchable, and accessible to people throughout a company, at the same time as creating a cooperative and helpful culture capable of boosting knowledge production and guaranteeing convergence and quality through highly egalitarian collaboration.

Social Network Analysis and Business Intelligence

Howard Dresner, a Research Fellow at Gartner Group, popularized the term business intelligence as an umbrella term to describe a set of concepts and methods to improve business decision making using fact-based support systems. This discipline aims to describe how end users could access and analyze information stored on their company systems in order to provide a better understanding of the business and its customer. To do this, they used a broad category of applications and technologies for gathering, providing access to, and analyzing data from the earlier business activities for the purpose of helping enterprise users make better business decisions.

Much of the early research in this field took place before the widespread use of the Internet and even corporate e-mail. We now need to understand the implications of Enterprise 2.0 technologies in the process of sharing business intelligence (Barquin, 2006). Web 2.0 can be seen (as it has been explained previously) as the ability to communicate and share knowledge with other participants that have similar interests, resulting in a key means of producing, communicating, and sharing business intelligence. In this line, this chapter focused on describing how Enterprise 2.0 can be used to spread, publish, and manage data from previous business activities through a new breadth of collaborative social knowledge networking tools like blogs, wikis, messaging, e-mail channels, and so forth, improving the added value outlined in enterprise business intelligence.

In previous sections, we showed how the Enterprise 2.0 vision introduces new channels and platforms that enable distributed production, communication tracing, and high commonality of information and services simultaneously. Apart from making information and knowledge work practices and outputs far more visible to the entire company, another key advantage pointed out during the chapter is that it can be used to carry out *social network analysis* of *business intelligence*. This is primarily concerned with the paths that information exchanges take between individuals and the fact that some individuals act as key nodes in the network and become critical factors in the successful communication and sharing of business intelligence.

Social network analysis allows us to identify the pathways that *business intelligence* must travel if it is to be used, integrated, enriched, and applied by individuals within enterprises. It will help to identify which the critical nodes are. Star nodes usually represent key points in the routing at which important intelligence can be either effectively tunneled to other network members that share the same interests or are working on the same type of problems or tragically choked, as we have seen up to now. Star nodes have been identified in almost any work environment grouping knowledge workers. Social network analysis is a powerful tool for improving a company's intelligence capabilities. Therefore, business intelligence analysis should be carried out not only on the content of communications, but preferentially on the structure of the social network, its topology, communication patterns, and links to identify the key nodes.

Business Process Management Revisited

Finally, BPM represents another key area in which Enterprise 2.0 vision will help to make great improvements. It is generally accepted that the current orchestration, BPM and workflow systems and technologies have failed to achieve a seamless automation and integration of business processes. Although there are currently a lot of approaches and standards in this respect, none of them seems to offer a sound solution to real enterprise needs. Most of the problem lies in how they handle the knowledge acquisition process for automating business operations. As we have seen, *Enterprise 2.0* provides a new approach to this problem that integrates flexibility, human interaction, and modeling facilities (different from the flowchart-based or the algorithmic approaches, and now based on networks of resources and interrelationships). Following the exposition carried out it is simple to find out the need to apply the Enterprise 2.0 approach to improve and evolve this kind of systems.

CONCLUSION AND FUTURE TRENDS

In this chapter we have explored emerging Internet technologies, highlighting their potential for supporting business Web strategy as companies' reliance on new Web-based technologies to capitalize on new business opportunities increase quickly. Specifically, Enterprise 2.0 has been presented as a key enabler for businesses to expand their ecosystems and partnerships, as well as acting as a catalyst for improving innovation processes and knowledge work in general. On the one hand, we have elaborated on the concept of Enterprise 2.0 mash-up as the main technological enabler of a global, user-centered SOA that spans company boundaries. On the other hand, we have discussed the most relevant Enterprise 2.0 models and tools suitable for fostering emergent collaboration and cocreation, thus enabling firms to leverage desirable attributes, including harnessing collective intelligence and organization by participation.

The key idea behind the Enterprise 2.0-based approach to a business Web strategy, and the lesson many businesses must learn, is that next generation IT systems must be conceived to acquire the knowledge they operate on directly from who really has it, that is, the employees (seen as knowledge workers) and from the operation and communication processes employees enter into. The knowledge of a business has less to do with the IT infrastructure than with the employees themselves. The IT infrastructure must be capable of extracting and managing that knowledge in order to evolve and adapt it to the business processes, and finally to the business strategy. Any other means to model and exploit the business knowledge will never be flexible enough. If user knowledge changes (and it does change), both the IT infrastructure and the business strategy must seamlessly adapt to such changes.

Future work would concentrate on evolving practical Enterprise 2.0 frameworks, as open source packages of technologies, tools, and platforms that build on all the key technical and theoretical enablers described above and on the proposed model of collaboration and enterprise knowledge emergency. We expect this framework and its pragmatic application could have great research opportunities within the domain of the topic.

Chapter 6.2
Web Engineering in Small Jordanian Web Development Firms:
An XP Based Process Model

Haroon Altarawneh
Albalqa' Applied University, Jordan

Asim El-Shiekh
The Arab Academy for Banking and Financial Sciences, Jordan

ABSTRACT

Small firms do not have the managerial experience, the financial resources and the methodological know-how to manage web-based applications projects the way large firms do. Many small firms are unaware of existing software process assessment models and standards. There's often the assumption that assessments conformant to these models and standards can be expensive and time consuming, and therefore difficult to perform in small companies. This chapter proposes a theoretical model for small Web project development and its special features in the context small Web firms, which are capable of being "tailor able" to the particular stage of organizational development of small Web firms . The process model derived form Web engineering best practices, real case studies from Jordanian Web firms and agile development methodologies (extreme programming) . This chapter also contains results from tow surveys: a questionnaire to Web developers and interview with Web mangers in Jordan.The results reflect the Web industry situation in small Jordanian firms, and the major problems they face. Most of small Web projects in Jordan run over time and budget, due to the ad hoc development and the weakness of Web project management. The results showed that there is a weakness in applying Web engineering practices in small Jordanian Web development firms.

INTRODUCTION

"Web Engineering is the application of systematic, disciplined and quantifiable approaches to development, operation, and maintenance of Web-based applications"(Deshpande Y and et al 2002). It is a response to the early, chaotic development of Web sites and applications as well as recognition of a divide between Web developers and conventional software developers (Murugesan, S et al 1999, Pressman 1998). Viewed broadly, Web Engineering is both a conscious and pro-active approach and a growing collection of theoretical and empirical research. Web engineering is the process used to create high-quality Web-based systems and applications that deliver a complex array of content and functionality to a broad population of end-users (bouchaib bahli and dany di tullio 2003). Web Engineering is concerned with the establishment and use of sound scientific, engineering and management principles and disciplined and systematic approaches to the successful development, deployment and maintenance of high quality Web-based systems and applications (Web Engineering Home Page 2003).

Web-based applications are becoming so popular in our daily life in the sense that it would not go a single day without we use them. These applications range from simple to sophisticated ones, where millions of dollars in revenue are generated. Developing, testing and quality assuring these applications become a challenging task (Abdesselam Redouane 2002). Although the development of Web-based applications made many improvements, there is still a lack of an established software engineering methodology for constructing Web-based applications. Consequently, much of the development is carried out without a true understanding of analysis and design issue.

The development of Web applications (E-commerce systems, Web portals, etc.) is subject to different conditions than that of conventional software systems (Said Hadjerrouit 2001). Such idiosyncrasies include: usability, rapid development lifecycle and short time to market. Web based systems and applications deliver a complex array of content and functionality to a broad population of end users. They require new approaches to design and development but present the same issues and challenges as traditional information systems. Therefore, the same software engineering techniques are still necessary but the process should take these differences into account.

Web-based applications differ from other applications from both the product and process point of view. As products, they differ from traditional systems in the following ways:

1. Web based applications are distributed and component based.
2. High reliability
3. High Usability
4. Security

Web applications also differ from traditional applications from the process point of view: there are more Technologies (HTML, XML, network protocols, multimedia, and Java and script languages) and thus, many Roles (authors, developers, graphic designers, legal issues etc.) that have to be managed. In addition, the shorter time to market, shorter product life cycles and continuous maintenance are much more pronounced in the case of Web applications as compared to traditional ones(D. Rodriguez et al 2002).

WEB PROJECTS DEVELOPMENT

The history of Web development is relatively short. Initially, many Web applications were small and simple with little thought given to planning or design before constructing the site, and few have been tested properly. Today, many applications are large-scale and involve sophisticated interaction with visitors and databases; such sites are often regarded as mission critical. In parallel with this evolution, a need for Web engineering has become apparent. Yet, within education, the plethora of Web courses primarily address the implementation of Web sites with very little about the analysis and design of Web applications. We believe that an early consideration of a Web engineering process suited for inexperienced users is important.

(Pressman 2003) says Web Engineering is not a perfect "Clone" of software engineering but it borrows many of software engineering's fundamental concepts and principles, emphasizing the same technical and management activities. The brief history of systems development methodologies identifies and explores eras of development and speculates on their future. Today's "post methodology" era involves methodologies that can be viewed by developers as outdated and inappropriate for rapid development, Web applications, and other current requirements. Perhaps we are in danger of returning to the bad old days of the pre methodology era and its lack of control, standards, and training (David E. Avison and Guy Fitzgerald 2002).

(Yogesh Deshpande and Martin Gaedke 2005) mentioned that "There are very few standard methods for the Web developers to use. Hence, there is a strong need to understand and undertake Web Engineering". Ad-hoc development of WBA has brought disasters to many organizations. A survey on Web based project development by the (Cutter Consortium 2000) highlighted problems for Web-based projects:

- Delivered systems didn't meet business needs 84 percent of the time.
- Schedule delays plagued the projects 79 percent of the time.
- Projects exceeded the budget 63 percent of the time.
- Delivered systems didn't have the required functionality 53 percent of the time.
- Deliverables were of poor quality 52 percent of time.

SOFTWARE PROCESS IMPROVEMENT

Software process improvement (SPI) assessments are considered by many small software development firms to be too expensive (Aileen 2004). Software process improvement (SPI) is defined as having the potential to improve competitiveness by increasing productivity; reducing costs, defect and rework; and improving time to market and customer satisfaction (M. E. Fayad et al 2000). Small software development firms recognize that software process assessments play a valuable role in improving a firm's processes and products, but most feel that SPI costs too much and takes up resources needed to deliver products. SPI is very important now days, where in the last 15 years, interest in SPI has increased as evidenced by the growing number of journal articles which include the phrase 'process improvement' in their title or abstract (L. Pringle 2001) .

Most of the empirical studies on SPI relate to large well-resourced organizations. It has been noted that very little is known about the experience of small software development firms in regard to SPI. The growth of the software industry has produced many small companies that do not do contract software, but rather compete in other areas. This gives rise to at least four significant development issues that have not been adequately addressed in software engineering literature: company size, development mode, development size, and development speed. . Definitions of "small" businesses vary by industry and by government agency from 100 to 500 employees or more. These bounds are somewhat broad for our purposes. Based on census data, we define companies of 50 or fewer employees as small (Mohamed E. Fayad et al 2000).

First step toward process improvement is identifying the strengths and weaknesses of an organization's software processes to determine effective improvement actions. An assessment can help an organization examine its processes against a reference model to determine the processes' capability or the organization's maturity, to meet quality, cost, and schedule goals (Christiane Gresse et al 2006).

A study by (Sebastian Stein 2006) showed that software process improvements are required to increase the productivity of software companies. Generally, it is the aim to increase the quality of the produced software and to keep budget and time. Quality models for software process improvements were developed in context of large organizations and multi-national companies.

AGILE DEVELOPMENT METHODS AND WEB ENGINEERING PRACTICES

The field of software development is not shy of introducing new methodologies. Indeed, in the last 25 years, a large number of different approaches to software development have been introduced, of which only few have survived to be used today. The term agile has recently been used to categories a number of lightweight approaches to building software. These include: Extreme Programming (XP), Adaptive Software Development and Dynamic Systems Development Methodology (DSDM). Seventeen advocates and methodologists of the aforementioned and other agile processes convened in February 2001. The result of this meeting was the formation of the Agile Alliance (Beck K. et al 2001)and the production of The Manifesto for Agile Software Development (Fowler M. & Highsmith J 2001).

The following quote from The Manifesto for Agile Software Development1 gives a summary of it's purpose:

"We are uncovering better ways of developing software by doing it and helping others do it. Through this work we have come to value:

i. Individuals and interactions over processes and tools.
ii. Working software over comprehensive documentation.
iii. Customer collaboration over contract negotiation.
iv. Responding to change over following a plan.

That is, while we value the items on the right, we value the items on the left more."(Constantine L 2001).

Ultimately we believe that the developers and organizations involved in Web engineering projects are the primary factor in the success or failure of Web application development. Given the diversity of disciplines required to develop Web-based applications, we are of the opinion that the AWE Process, or any other process or methodology, can only hope to have a second order effect on project success. Thus, we hold the belief that the agile route with its focus on people.

Our belief that people are the most important factor in project success is the fundamental reason why we have not tried to develop a monumental process to tackle the problems associated with Web application development. Many monumental processes attempt to codify good practice and experience in too much detail and for developers who do not understand the importance of what they are doing! This often results in development projects using monumental processes as cookbook recipes, where developers are lulled into a false sense of security by following the recipe in detail rather than using the ingredients selectively to help them build software deliverables that solve their problem space.

AWE is an iterative and incremental process; we believe this will allow for: early and continuous delivery of valuable software; the ability to harness changing requirements, even late in development; and the delivery of working software frequently. The AWE Process supports multidisciplinary development treating business experts, domain experts, and creative designers as developers along side software engineers (Miller, G 2001)

The following are the characteristics of agile software processes from the fast delivery point of view, which allow shortening the life-cycle of projects:

1. Modularity on development process level
2. Iterative with short cycles enabling fast verifications and corrections
3. Time-bound with iteration cycles from one to six weeks
4. Parsimony in development process removes all unnecessary activities
5. Adaptive with possible emergent new risks
6. Incremental process approach that allows functioning application building in small steps
7. Convergent (and incremental) approach minimizes the risks
8. People-oriented, i.e. agile processes favor people over processes and technology
9. Collaborative and communicative working style (Miller, G 2001).

Surveys of Web engineering practice by (Andrew McDonald and Ray Welland 2002) have identified seven characteristics of Web engineering that must be addressed by a Web engineering processes. These are support for:

1. Short development life-cycle times
2. Different business models (Business Process Re-engineering)
3. Multidisciplinary development teams
4. Small development teams working in parallel on similar tasks
5. Business Analysis and Evaluation with End-Users
6. Explicit Requirements and rigorous Testing against requirements
7. Maintenance

Since agility is desired, the principles of Agile Modeling should be followed.

Most of today's Web application development processes are extensions of standard software engineering processes. The usual iterated waterfall model is too rigid an approach to developing Web Applications. The waterfall model process was perfect for developing a file maintenance program for mainframes, but far too restrictive a process for building a Web application. Web application development needs to be an iterative process and most agree that a spiral approach is best. But, the exact steps at each cycle of the spiral are debated, as is the metric to be used to determine the completion of a cycle.

A few of today's Web application development processes have been derived from a business- oriented approach to applications development (Standing Craig 2002). Most of these processes develop a business plan for the e-business associated with the Web application, sometimes re-engineering the business along the way, and use things like Return on Investment (ROI) as a metric for the Web application development process

Extreme Programming

Extreme Programming (XP) has evolved from the problems caused by the long development cycles of traditional development models.

It first started as "simply an opportunity to get the job done" (Beck, K 1999) with practices that had been found effective in software development processes during the preceding decades (Beck, K 1999). After a number of successful trials in practice, the XP methodology was "theorized" on the key principles and practices used. Even though the individual practices of XP are not new as such, in XP they have been collected and lined up to function with each other in a novel way thus forming a new methodology for software development. The term 'extreme' comes from taking these commonsense principles and practices to extreme levels.

XP consists of 12 related practices and works best for small teams of 5 to 15 developers. Rather than focus on paper-based requirements and design documentation, XP concentrates on producing executable code and automated test drivers. This focus on source code makes XP controversial, leading some to compare it to hacking. We believe this comparison is unjustified because XP highly values simple design, and counters hacking claims by emphasizing refactoring, strong regression testing, and continuous code inspections through pair programming (J. Zettel et al 2001).

Small Firms and Standards

Many small firms are unaware of existing software process assessment models and standards. There's often the assumption that assessments conformant to these models and standards can be expensive and time consuming, and therefore difficult to perform in small companies. Small organizations also perceive assessment models and standards—including documentation and process-formalization practices—as targeting large organizations (M.C. Paulk 1998).

Small firms do not have the managerial experience, the financial resources and the methodological know-how to manage Web-based applications projects the way large firms do. Yet despite this, some small firms are satisfying their software development needs offshore (Brian Nicholson and Erran Carme 2002) There are two battles over process that every small software company must win to be successful. The first is the battle to convince the company to adopt reasonable development processes. Discussion of what makes up a good process may be an interesting meditation, but is entirely moot until the company commits to a policy of process improvement. The second battle is never over. It is to change existing processes to match changing circumstance (Robert P et al 2001).

A first step toward process improvement is identifying the strengths and weaknesses of an organization's software processes to determine effective improvement actions. An assessment can help an organization examine its processes against a reference model to determine the processes' capability or the organization's maturity, to meet quality, cost, and schedule goals. Several software process assessment models have been developed, such as CMM/CMMI, ISO 9001 Quality Management (including 9000-3), and ISO/IEC 15504—sometimes called SPICE. However, small companies (1–49 employees) find it difficult to run assessments (T. Mäkinen 2000).

SURVEY METHODOLOGY

The units of analysis for the survey were Jordanian small Web firms undertaking Web development. The target population included all small firms in Jordan which develop Web applications for sale as well as in-house software development groups within firms. The SEI [10] questionnaire was used as the survey instrument. Prior to the data collection, the survey instrument was pre-tested to enable clarification of constructs; to provide the means of operationalising selected constructs; and because pre-tests can be useful in qualitatively establishing the reliability, construct validity, and content validity of measure. In order to locate and correct weaknesses in the questionnaire, the questionnaire was pre-tested using face-to-face interviews with 10 random developers. The selection of interviewees for these pre-tests was designed to obtain maximum feedback from Web developers in various roles.

Prior to the pre-test, the following checklist was used to review the questionnaire instrument:

- Will the words be uniformly understood?
- Do the questions contain abbreviations or unconventional phrases?
- Are the questions too vague?
- Is the question too precise, biased or objectionable?
- Is it a double-barrel question?
- Does it have a double negative?

- Are the answer choices mutually exclusive?
- Has too much knowledge been assumed?
- Is the question technically accurate?
- Are the questions too cryptic?

During the pre-test, concerns were raised about the section headings and question groupings of the SEI questionnaire (such as metrics, standards and procedures, control of development Process). During the pre-test, the respondents completed the questionnaire in the presence of the researcher, and identified any difficulties with interpretation of words or questions. As well as testing the reliability and construct validity, the pre-tests served as 'dry runs' for the final administration of the instrument. The feedback was not adequate. So, some parts of the questionnaire were translated into Arabic Language (the mother tongue of respondents), and the pre-test was carried a second time. The sample used consisted of twenty small Web development firms in Jordan. Firms were eligible for inclusion in the survey when they (1) have had developed Web applications during the last 12 months and (2) did not have more than 50 employees.

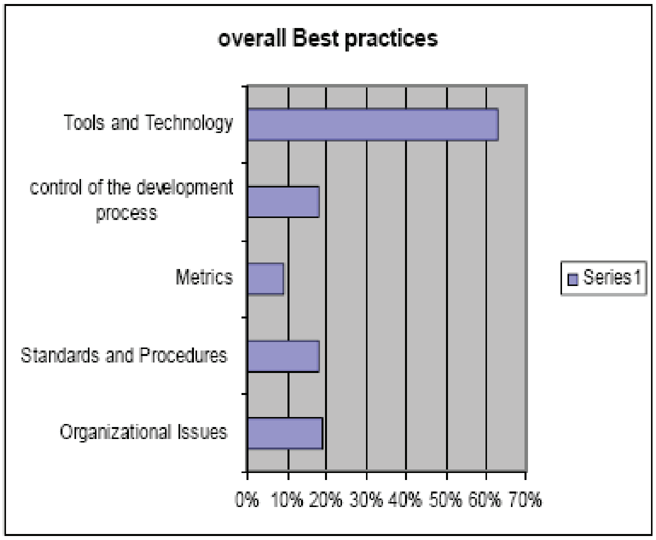
The questionnaire is organized into two sections. The first section collects information on the respondent's background.

This includes current position, past experience, roles played among others. The second section, entitled Web engineering best practices, concentrates on the adoption of best practices by the respondent's organization. These include organizational Issues, standards and procedures, Web metrics, control of the development process, and tools and technology.

RESULTS

The statistical analysis showed that the majority of respondents have 5 years or less of experience in their present organizations, and the same number of years of overall software experience. The majority of them are in software engineering process group positions. The highest percentage of the study participants is involved in design activities. The majority of the participants were never involved in software process improvement activities. The analysis showed a significant weakness in the levels of adoption of Web engineering practices by small Jordanian Web development firms. The ratios of adoption levels were as follow: organizational issues (19%), standards and procedures (18%), Web metrics (9%), control of the development process (18%), and tools and technology (63%). The statistical analysis shows that Web metrics got the lowest ratio; which implies that the majority of respondents are not familiar with this practice. Tools and technology got the highest ratio; which implies that this practice is the most applied practice in these firms, and this reflects the widespread use of these tools in the development process worldwide. Organizational issues, standards and procedures and control of the development process got similar ratios. But, for the organizational issues, and standards and procedures, the majority of respondents answered with "No". This implies that the majority of respondents are not familiar with these two practices. For the control of development process practice the majority of respondents answered with "Does not apply". This implies that the respondents are familiar with this practice, but they don't apply it, and this leads one to say that the development process models used by these firms are ad hoc. The analysis also showed that there are significant differences in the levels of adoption of Web engineering best practices between European firms and small Jordanian Web development firms. The overall average of adoption levels of best practices in European countries is 51%, while the overall average of adoption levels in small Web development firms in Jordan is 25% see (Figure 1). The big difference in average between them implies that there is a big gap between the adoption levels of best practices in European countries and

Figure 1. Overall best practices adoption in small Jordanian firms



small Web development firms in Jordan. The final conclusion is that small Web development firms in Jordan have a lot to do in order to succeed in a very competitive market.

The Model

According to (Abdesselam Redouane 2002) Web-based firms have very stiff and stringent conditions. They have limited resources. This will hinder the quality of the product and ultimately the success of these companies. It is usually the case that the few people, who carried out the development, will also perform the testing of the end product. This is a poor practice, as it does not allow the test to be carried out rigorously and it will be certainly biased.

According to the results we got from the surveys that we have done, we found that small Jordanian firms have many problems:

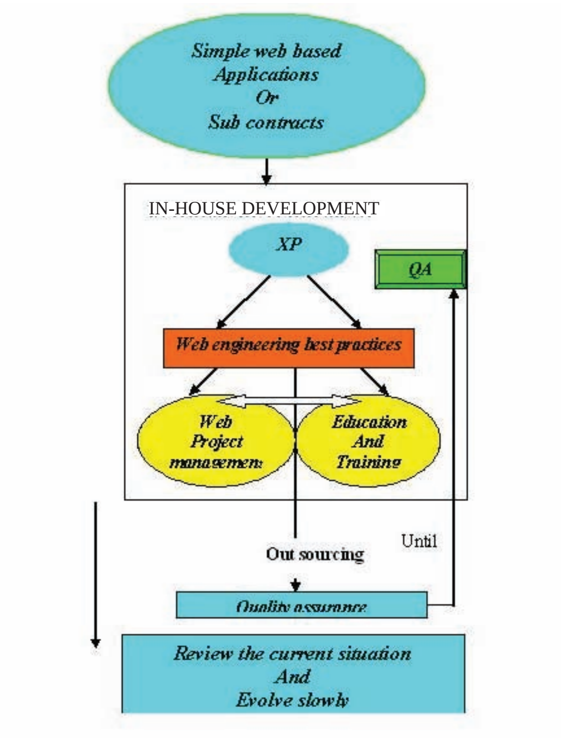
Web projects are always, in most cases (firms) run over budget and time , have limited resources, number of developers is very small, quality assurance activities are done by the people who carried out the development, add hoc development approaches used , poor Web project management, and Web engineering practices is not implemented .

Based on results of survey and literature analysis we proposed the following model (Figure 2):

1. Start with simple Web projects or implement sub contracts projects: The surveys and literature stated that most of Web development projects in small firms are small or medium size projects (1-2 months or 3-6 months). In small Web projects it is highly desirable to plan all phases at the start of the project. This means that the phase sections of the Web project management plan, Web configuration management plan and Web verification and validation plans are combined. The plans may be generated when writing the proposal. Typically, qualified developers are involved in large or medium-size projects whereas small Web projects are carried out by under-qualified or inexperienced Web developers. The reactionary development scenario and the lack of clear guidelines to face the process, push developers to follow an ad-hoc development process.

   The heavyweight software methodologies

Figure 2. The model



are limited to support such scenario. This is because they involve several stages and roles that require an important amount of communication and coordination in order to get a final product. On the other hand, there are the lightweight or agile methodologies that could have an interesting applicability to the described scenario.

2. Implement an agile development model, and we recommended using extreme programming that identify specific best practices within the Web development domain: Different software development methodologies and quality assurance methods are used in order to attain high quality, reliable, and bug free software. Extreme Programming (XP) is a software development methodology that integrates many of the known ideas (that we all were familiar with) in order to achieve such software systems. Specifically, XP emphasizes code-unit testing (preferably before its writing), and thorough testing of software functionality. The contribution of XP to software development is expressed, among other ways, in the quality improvement of both the entire process of software development and of the software quality itself. Currently, XP is used mainly in small-medium size software projects [19].
3. Developers must apply the lower limit of Web engineering best practices: Many practitioners in the field of Web engineering and software engineering have commented on the lack of suitable software engineering processes that can be used to build Web applications. We investigated the way industrial Web engineering is being carried out by making a survey consists of questions relating to the development process being used to develop Web applications and Web engineering practices. If a Web engineering process is to be successful then it must address the following:
    1. Short development life-cycle times.
    2. Delivery of bespoke solutions.
    3. Multidisciplinary development teams.
    4. Small development teams working in parallel on similar tasks.
    5. Analysis and Evaluation.
    6. Requirements and Testing.
    7. Maintenance.
4. Testing and quality assurance (QA) activities must be carried out by another qualified firm, until an internal qualified quality assurance department is established
5. Web project management issues specific to Web development; must be carried out.

   In order to organize and manage a Web development project successfully, one must combine specific knowledge, skills, efforts, experience, capabilities, and even intuition.
6. Training and education: Good Web engineering practice requires expertise in a complex

set of activities that involve the intellectual skills of planning, designing, evaluating, and revising. A Web engineering process must take into account the different types of developer required to build a successful solution.

In order to this framework to be successful, all of the people involved in Web development (developers, mangers,) must have a good knowledge in Web engineering development and they must be trained.

The best way to learn modified XP is in an experiential-learning training course. Your entire development team (including the testers, the customer, and the manager)

Should attend a one-week immersion course on XP. While many programming teams are learning XP based solely on books and information on the Web, it is important to actually do the practices with guidance.

7. Review the current situation; evolve slowly, until development method is clear.

Figure 2 shows the model and explains the model elements.

CONCLUSION

The results showed that there is a weakness in applying Web engineering practices in small Jordanian Web development firms. The results of the study lead to the following recommendations to improve Web development practice in small Web development firms in Jordan:

1. Development teams should be multidisciplinary: A Web engineering process must take into account the different types of developer required to build a successful solution. The process

   Should ensure that all involved understand their roles and responsibilities, and where overlap occurs understand how to resolve conflict in the best interests of the project in question.
2. Firms should apply project management best practices to improve organizational issues.
3. Firms should pay attention to the quality management and standards.
4. Firms should apply software engineering best practices to improve the execution of their Web engineering projects.
5. Software process improvement initiatives should be considered.
6. Education and training: A proper and regular training of employees especially on newer aspects in Web engineering will lead to an increase of acceptance and usage.

Small firms need to adopt a suitable Web development model and must apply Web engineering best practices in order to survive. Web project management and education is also important for the development process. Testing is the main key for quality, so small firms should outsource their testing activities at the initial phases when apply the model. The model may be helpful for small Web firms in improving their way in development, where small Web firms have very stiff and stringent conditions. They have limited resources.

The model may be considered useful for Web project development in small firms, where it based on agile development methods, a set of Web engineering practices, and Web project management.

KEY TERMS AND DEFINITIONS

Agile Development: Refers to a group of software development methodologies that are based on similar principles.

CMMI: A process improvement approach that provides organizations with the essential elements of effective processes.

Extreme Programming: Is a software engineering methodology, the most prominent of several agile software development methodologies.

Small Firms: Small firms are companies which employ a relatively low number of workers.

Software Process: The total set of software engineering activities necessary to develop and maintain software products.

Web-Based Applications: Is an application that is accessed via Web browser over a network such as the Internet or an intranet.

Web Project Management: Project management is a methodical approach to planning and guiding project processes from start to finish.

ONO, Spain

ABSTRACT

Employee life-cycle processes management (hiring new employees, changing their conditions, and dismissing them) is a critical task that has a big impact in HR Information Systems. If these processes are not handled correctly the consistency of HR databases is compromised. In many cases (especially in small and mid-size business) these processes are implemented using semi-manual procedures based on unstructured information. In this chapter the authors will present the results of our real-world experience building a Web-enabled workflow system for managing employee life-cycle process instances in the context big Spanish telecommunications company.

INTRODUCTION

Employee life-cycle management is a critical task that affects all companies without regard of their size and business. These processes include hiring new employees, changing working conditions (promotion, demotions, change of cost centre, changes in the compensation package, change of function, change of organizational unit, etc.) and dismissals (end of relationship). In this paper we will present our real-world experience building a web-enabled

DOI: 10.4018/978-1-60566-304-3.ch020

workflow system for managing employee life-cycle process instances in a big Spanish telecommunications company. In the first section we will present ONO, our company, in order to set the organizational context. In the second section we will present the problem that we faced and set the requirements for building a tool to solve it. In the third section the web-enabled workflow system is presented, making special focus on the agile approach used to build it and how the previously stated requirements are met. Finally we will offer some conclusions and future lines of work

About ONO

ONO is the leading alternative provider of telecommunications, broadband Internet and pay television services in Spain and the only cable operator with national coverage. ONO offers its services to more than 1.8 million residential cable access and 69,000 business customers as of 31 March 2007, through its own state of the art networks which give direct access to nearly six million homes in franchises that cover the majority of Spain, including the nine largest cities. ONO is the principal competitor to the incumbent telecommunications and pay television operators in Spain. For the first Quarter 2007, ONO generated revenues of €1,608 million and EBITDA of €592 million, on an annualized basis. ONO has several offices all around Spain.

Ono is a young company in constant growth in search of excellence. Throughout its history has demonstrated great management skills and solid growth prospects, backed by a strong global investment in an infrastructure that reaches 6.8 million homes. Table 1 shows chronologically the main highlights that significantly transformed our company.

BACKGROUND

In this section, we will present our notion of employee life-cycle process and how it is related

Figure 1. ONO Spanish coverage and operating highlights. ONO offers their services to clients in almost all the national territory, covering more than 17.500 homes in Spain (according the Spanish INE)

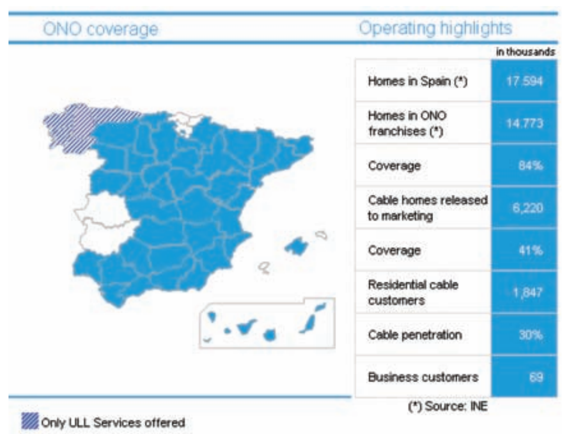

Table 1. Company background (chronologically)

Year	Event
1998	The ONO brand was launched in 1998, and was awarded the licenses to provide cable television and telecommunications services in the regions of Valencia, Castellon, Alicante, Murcia, Cadiz, Huelva, Cantabria, Mallorca, and Albacete.
2002	By the end of 2002, ONO was already present in approximately one in every three homes prepared to receive its services.
2003	In 2003, it was awarded the licence to operate in Castilla – La Mancha.
2004	In 2004, it acquired the telecommunications operator Retecal, covering Castilla-Leon.
2005	In November 2005, ONO closed the acquisition of 100% of the telecoms company Auna Tlc, extending its services to the communities of Madrid, Catalonia, Aragon, Andalusia (excluding Cadiz and Huelva, which already belonged to ONO), the Canary Islands, Catalonia, La Rioja, Madrid and Navarra.

to e-HRM. Following, we will detail how this processes where run at our company in our initial scenario to show their fragility and resource consumption intrinsic problems.

Employee Life-Cycle Process

We call "*employee life-cycle process*" to any process that modifies the conditions of an employee within our company. These processes include hiring new employees, modifying any of her contractual conditions (changes in the compensation, position, department, location, bonus, etc.), and dismissal. These processes are critical for the reasons detailed in the next paragraphs.

Employee Life-Cycle processes provides the input for HR databases. Therefore, if they are not managed correctly the consistency, organization, and trustworthiness of the information in HR databases are compromised.

They are run collaboratively by groups of persons that may not know each other and may be geographically dispersed (in different cities, states, countries, or continents, depending on the size of the company). Usually each process instance must go through a hierarchical approval workflow (e.g., hiring of a new employee requires an approval of the manager of the requester). When the processes are not formalized enough these workflows mutate on a case-by-case basis, hindering control over the ongoing processes.

Since they deal with information of people and this information is handled by people, there are non-formal issues that may arise (anxiety, envy, information protection, corporate politics, etc.) and may require special attention of the HR team.

The last (but not least) important issue regarding these processes is budget control: each one of these processes affects directly the HR budget for the company. Without budget control departments can hire above the HR budget forecast of the company.

Weak vs. Strong Employee Life-Cycle Process Management

An inefficient (non automated, non formal, non controlled) employee life-cycle process management results in lots of manual, repetitive, boring, low value, and error prone tasks that must be done by the HR team. All companies with a basic implementation of the HR module of SAP (or similar) may be doing a very basic management of employee life-cycle processes (all changes are recorded in a centralized database). However, there is no formal support for the approval workflow, nor management of the people issues at the stages before the data is introduced in the database. In these implementations, the processes may be performed manually (or semi-manually or using unstructured information sources like email). In this case the HR team needs to do an enormous amount of back-office low added-value work: paper chasing, consolidating requests, check for collisions when dealing with a particular request, manually creating reports, deal with each process as a "state-of-the-art" unit, control the HR budget, ensure privacy of information, normalize inconsistent input, etc. (the list could go for several lines more). We call this "weak employee life-cycle process management".

In contrast, when these processes are managed correctly they can change the way HR works within a company since all the manual, boring, error prone, and low added-value work is removed allowing HR people to innovate, drive, envision, and improve the organization. As a plus, upper management has up-to-date just-in-time information on the state of on-going employee life-cycle processes and real time information about the current HR budget. We call this "strong employee life-cycle process management".

Employee Life-Cycle Process and e-HRM

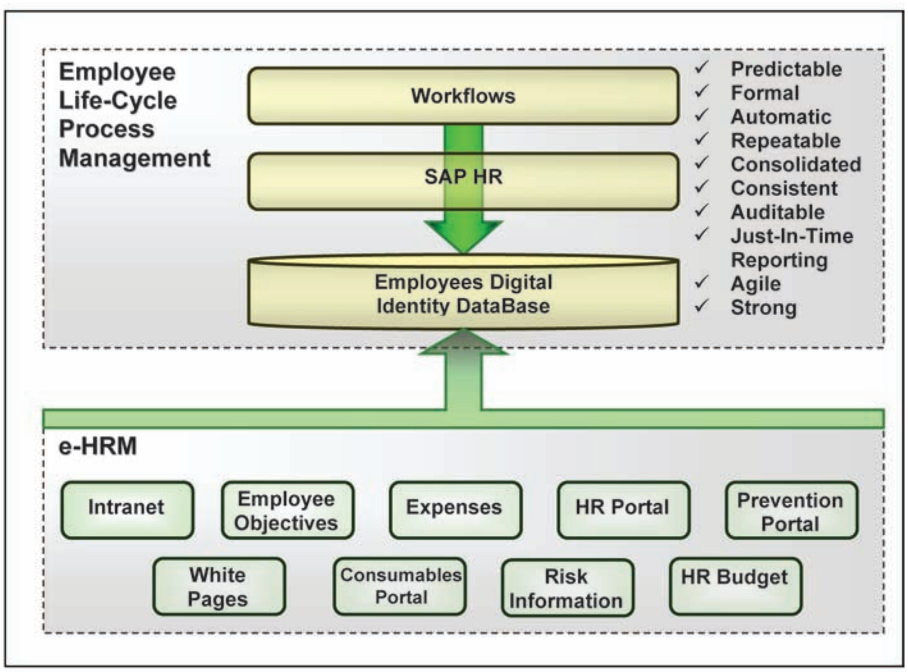
Ruël, Bondarouk and Looise (2004) state that e-HRM is a way of implementing HR strategies, policies, and practices in organizations through a conscious and directed support of and/or with the full use of web-technology. The use of web-technology may render in a set of Intranet based applications distributed within the company. Each one of these applications may focus on a concrete aspect of interest for the employee (Employee's Portal, Vacations Management, Travel Expenses, etc.) or the company (Objectives Management, Work Reports, Planning, etc.).

Each application may have been built to manage its "small universe" of information. However, there is a common denominator for all those applications: all of them deal with information about employees.

When strong employee life-cycle management is implemented within an organization we can expect a trustable source for accessing consolidated up-to-date employee information. In contrast, when weak employee life-cycle management is implemented we cannot guarantee the trustworthiness of our employee information repository (e.g. some processes may have been processed but not introduced in the system; a human error in consolidating thousand-of-excels may result in errors within the hierarchical structure of a department).

eHRM is feasible without a proper employee life-cycle process management, although not advisable (specially in large companies). Weak employee-life cycle process management has a big impact in all HR applications within a company regarding quality and reliability of its information and workflows. The lack of reliability, auditability,

Figure 2. Manual employee life-cycle processes management is error prone and time consuming, resulting in a weak employee's digital corporate identity on the employees. This creates the need for lots of manual or semi formal integration processes as an immediate negative consequence (represented by the arrows from each application to SAP HR)



and normalization in employee life-cycle process management leads to a weak employee's digital identity (who is a person within an organization, including position, department, location, duties, professional category, etc.). As a consequence, lots of manual or semi-formal integrations must be done, taking lots of hours of the HR department impeding them to do "interesting things". We could summarize this in the following phrase: "*HR is working for the System, but the System is not working for HR*".

Employee Life-Cycle Processes at ONO

In the last years, ONO experienced a very fast growth in a very short period of time (Table 1). The biggest leap was the merge with Auna (a company that had the same size than ONO at the time of the merge). One of ONO's main characteristics was being very agile, with very simple and human-centred processes. Some of them didn't scale to the new context of the company, since they were designed and implemented having another model of enterprise in mind. The employee life-cycle management support processes (hiring, changing working conditions, and dismissal) fell in this group.

Each of these processes were based on paper-printed documents (that in the best case where based in corporate Excel templates), with all the problems that this implies including inconsistency in the input (files were completed differently by the requestors), traceability (all the Excels were sent internal mail), problems for enabling teamwork (there wasn't any mechanism for dispatching the requests and therefore a single request could be handled incorrectly by several HR (Human Resources) employees at the same time), lack of a unified way for notifying the participants in the flow, lack of tools for reusing the requests, lack of reporting (there wasn't any automatic way to get a report of what was going on in the company), lot of human effort of very low added-value (HR managers consolidating hundreds of Excel files and e-mails), among other problems. To make things worst, ONO has a region-based organizational model (based on the division of the company in the Spanish geography), increasing the impact of the above mentioned problems.

Description of the Manual Employee Life-Cycle Processes at ONO

ONO is a young company, and therefore some of their processes matured in the last years and some of them are still maturing. The employee life-cycle management processes were manual, based in interactions among people that knew each other (at least by telephone). They were manual-run workflows where all the participants worked collaboratively on the same physical paper document.

Following, we will describe briefly (and in a broad way) how the processes were run:

1. A user creates a request document (for staring a new hire, a change in the conditions of one of his employees, or a dismissal). In the best cases this document was based on a corporate template. While this was the best case, it was far from being ideal: since the requestors weren't HR specialist (a petitioner could be any manager that needs to hire a new employee or to promote one of his employees) usually the document wasn't correctly fulfilled.
2. After the document was created and printed, it was signed by the petitioner and by her manager.
3. The petitioner notifies the HR department (by email or by phone) and then he sends the physical document by internal mail.
4. HR receives the document and validates it. If they need further clarification, they would contact the petitioner or her manager to discuss about the request.

5. In the case that the conditions of the hiring / promotion / change / etc. varied significantly after the discussion, a new physical document needed to be issued and signed again.
6. HR registers the transaction, contacts the employee that would be hired / promoted / fired / etc., does their usual tasks according the type of process, and registers all the information in their HR systems (payroll, SAP HR module, etc.)
7. Periodically (twice a month), the HR staff manually created reports of the ongoing processes to inform the upper management. They also used this information to verify that the HR budget wasn't overrun (this verification was also manual on a process-by-process basis).

The above description is a simplified version of the manual processes, with the goal to illustrate its fragility. It was very error prone, produced lots of unnecessary work, unreliable (in some cases, papers where lost and the process needed to be started over), and unique for each petitioner (according to her personality). It consumed lots of time of the HR team performing tasks of near-to-null value, such as verifying the input data and trying to interpret it, creating reports manually, tracking papers, notifying personally each of the actors in the process, and controlling the budget.

IMPROVING EMPLOYEE LIFE-CYCLE PROCESSES WITH A WEB-ENABLED WORKFLOW SYSTEM: AN AGILE APPROACH

In this section we present the main problem and our solution proposal. We start showing how our weak employee life-cycle processes (detailed briefly in the section "Employee Life-Cycle Processes at ONO") didn't scale when our company increased its size and rapidly became an important issue to be solved. Next is detailed how this problem derives in the need for a tool and establish a set of requirements for that tool. Following we elaborate on our response to the problem: creating a web-enabled workflow system using an agile approach. In order to make our ideas true we benefited from agile concepts for modeling the business processes and building the solution. The use of agile methods allowed us to create a high-functionality and quality application on a low budget with early and frequent deliverables.

ONO-AUNA Merge Related Problems

The process mentioned above worked fairly well in mid-to-low-size environment (less than 2.500 employees), with a relatively small HR department, and a very people oriented culture. Since the process was mainly based in human interactions, it worked better when the participants knew each other. Additionally, each instance of the process was highly dependant in the actors: some requesters (hiring managers in the hundreds of departments of the organization) where good "process players" and sent the information in good shape while others where very chaotic.

When ONO bought Auna and the merge started the company doubled its size. A manual process mainly based in interactions among people that knew each other didn't scale well in the new scenario, in one part because the size of the company increased but mainly because the people running the process didn't knew all their counterparts anymore (and given the new size of the company, it was very improbable that they would do ever).

To worsen things, the amount of HR transactions regarding employee life-cycle increased exponentially: is well known by everyone that in a merge process lots of new people come to the company, lots of people leave the company, and even more people changes position (in the average, there are two employees for each position, since both companies where in the same business).

A final added problem was traceability and auditability: since the process was based in physical paper sheets, it was mandatory to keep the original papers for a time period according with the Spanish law. During the merge, lots of work centre moves were done. Each move affected the paper files and therefore increased the difficulty to locate the papers (they could be lost or at any branch of the company). In these cases, lots of time of the HR was lost just doing "paper chasing".

The Need for a Tool

It was very clear that the company needed a tool to assist the employee life-cycle management, with the goal of making it easier, more reliable, predictable and auditable, to provide all the participants in the process the information they need just in time without any further hassle, and to provide the upper management with reporting tools to know the global picture regarding the overall HR budget of the company.

After jointly studying the problem ONO's HR and IT departments decided to build a set of tools to support the employee life-cycle processes. The main goal of these tools was to enable the collaborative work between all the actors implied in each of the employee life-cycle management processes. Each of these actors should be able to interact with the new tool in a very simple and efficient manner. Additionally, the tool should be proactive, providing a "push model": each participant in the process should be notified whenever a process instance requires his participation. The tool should support the approval workflow (Workflow Management Coalition, 1995) for each type of process, dynamic headcount validation and automatic reporting.

Requirements for the Tool

The following requirements where established by ONO's HR department:

- **HR budget control:** Provide an automatic control of the HR budget at all the appropriate levels. For example, when a new request is issued it should be checked against the requesting department HR budget to verify if the request is valid. At a higher level the upper management and HR directors need to have reporting facilities to have a general view of evolution the overall HR budget of the company.
- **Support for the approval workflows:** Model the manual processes using a workflow systems. This implies modelling semi-formal processes using formal specifications.
- **Enabling collaborative work:** The tool should allow each employee to participate in the approval workflow at the right moment. It should inform the participant in the flow of the new events that require their attention. It should also give a unique single point for checking the status of the on going processes (eliminating e-mail and phone).
- **Automatic reporting:** Generate all the reports automatically, without manual intervention.
- **Traceability and auditability:** All the process instances should be traceable and auditable, giving a fine grained control over the past events.
- **Reducing manual work:** Reduce all the low value added manual work.
- **Input consistency:** Simplify data input in order to give reduce ambiguity and improve consistency in data that enters to the approval flow.
- **Reduce bottlenecks in the process:** Provide tools to avoid a single person to stop all the ongoing flows when she is not available.
- **Ease of use and far reach:** Create a very easy to use tool in order to make the learning curve as low as possible. It should also

accessible by any employee of the organization without the need of any complex setup in his computer.

A Web-Enabled Workflow System as a Response to the Problem: Benefiting from Agile

After the problem was clearly established ONO's IT and HR departments started working on how to deliver a cost and time effective solution following ONO's cultural principles (Davenport & Prusak, 2000). The working group determined that the best approach for solving the problem was building a web-enabled workflow-based system, since it would empower the collaborative work on the employee life-cycle requests without any special requirement in the client computers.

The group also decided to build it with a low budget without sacrificing the quality and functionality, using the technologies and tools available at the company (mainly based in the development framework created by ONO's IT department). An agile approach was the methodological choice since it allowed to build small deliverables in short iterations, delivering value in small (but continuous) slots of time. In the economic side, this approach would allow to build with the resources at disposal: if the team was short on economic resources, it could do less ambitious iterations or even do no iteration without affecting the overall project (whenever any iteration was finished a new fully working module was delivered and deployed in production).

An Agile Approach for Modeling the Business Processes

The processes were modeled after a careful analysis of their manual counterparts. A joint work between One's HR and IT department was performed in order to come out with the most accurate representation of the business processes involved in the employee life-cycle.

The business process modeling was a very important part of the process: lot of tacit organizational knowledge needed to be transformed in explicit knowledge (Nonaka & Takeuchi, 1995) that can be used as a formal specification. It was a big challenge to come out with a model that clearly represents the interactions for each employee life-cycle process: since the process was semi-formal, there where significant ambiguities that needed to be resolved.

The main premise in this specification process was *simplicity*: our goal was to come out with the simplest process definition as possible. All the resulting flows are very similar: this is the result of a commonality analysis (Gamma, Helm, Johnson, & Vlissides, 1995) between all the processes in order to find all the similarities between processes and model them as uniform as possible to make them simpler and easier (Figure 3).

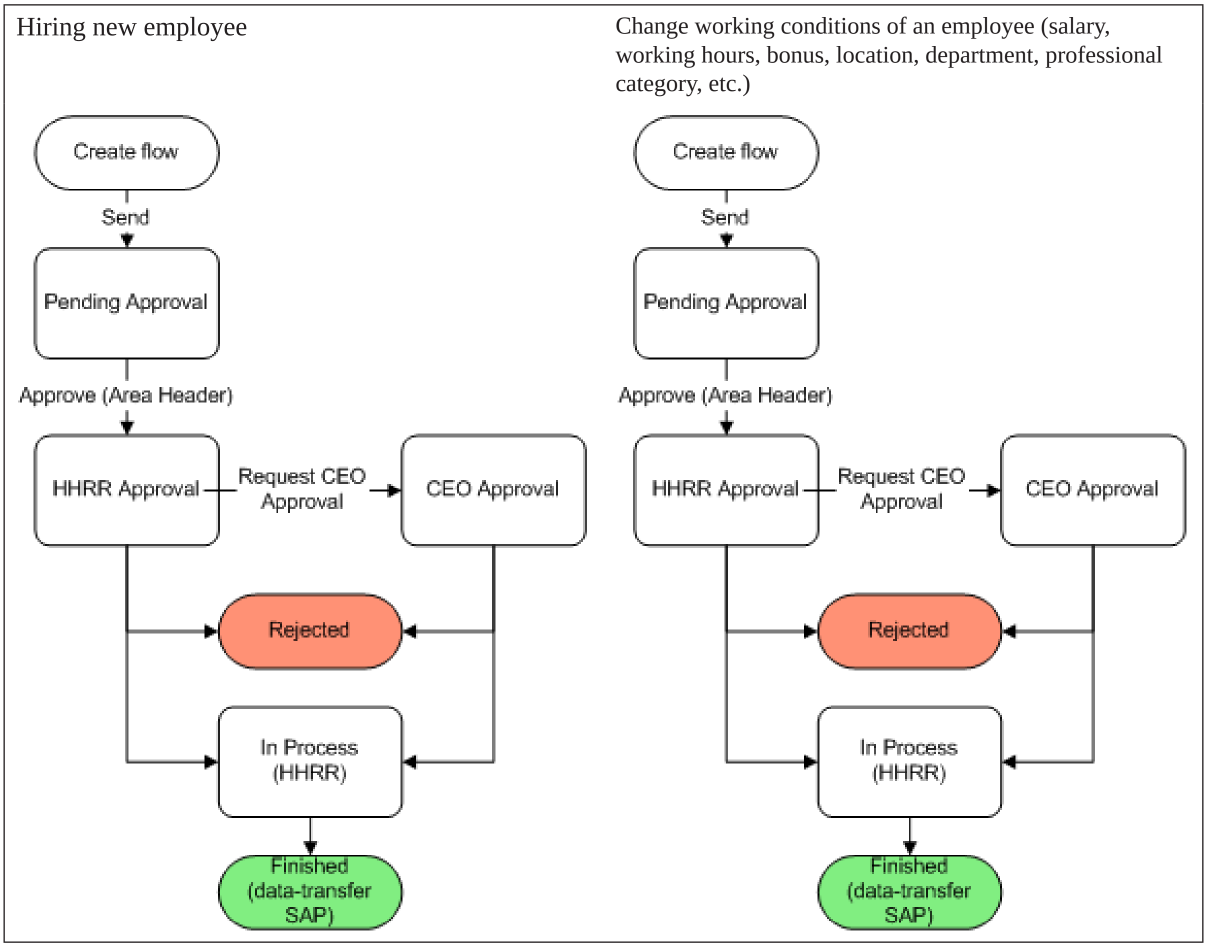
Observing, Learning Building, and Delivering: An Agile Approach for Modelling the Business Processes

We took an agile (Agile Alliance, 1999; Beck, 1999; Martin, 2002; Schwaber & Beedle, 2001) approach built our first model iteratively and incrementally: instead of trying to come out with the final version of the three flows up-front we went through several short iterations on the first one (the hiring process) and improved it using the feedback and experience gained from its real users.

We created a simple implementation of the hiring process according to the more immediate needs of HR. When it was in production we actively observed the problems and situations that arose to our users when using the tool and the error logs of the system. With all this information we built packages of fixes (in short sprints) and delivered new versions taking the same approach (observing, learning, building, and delivering).

This approach allowed us to constantly deliver value and to supply a working solution to our users without spending unnecessary time in the

Figure 3. After several iterations and commonality analysis, our "Hiring" and "Change of Conditions" flows are almost identical. In the manual process the flows where significantly different. Currently both flows are formal, determining automatically and in a predictable way their participants. The only difference among both flows is in the control of the HR budget (this is strongly checked on the hiring flow), but does not affect the flow neither the participants (the instance of the flow is marked with special information to indicate if it is or it is not within the forecasted headcount for the ongoing quarter)



analysis phase (lot of the changes that we included in the packages where product of our continuous improvement process).

An Agile Approach for Implementing the HR Workflow System

The Software Development area in ONO's IT department works under the principle of dividing big projects in small chunks in order to deliver functionality earlier in shorter intervals of time and with more client checkpoints. This allows building applications with smaller budget, deliver early working products to the clients, and giving them the chance to change or add new requirements after each iteration is finished. The main goal of our approach is to deliver value to clients in the shortest interval as possible and to evolve the functionalities based on real world information mined from the usage of the application (observe, learn, build, and deliver).

ONO's Software Development area uses a variant of SCRUM (Schwaber & Beedle, 2001). Each sprint (Schwaber & Beedle, 2001) starts with the creation of a scope document that is validated by IT and its clients (in this case, HR). After the document is approved, a high level architecture and high level designs are built and a product backlog is created. This backlog may also contain small user stories on each of its items. The backlog is revised on a daily basis doing stand-up meetings. In that stand-up meetings, some architectural or design issues may arise. In that case they are discussed later in other special purpose meetings, in order to make the daily stand ups as short as possible and not keeping all the members of the team busy with things that are not interesting for them. In our SCRUM variant, the sprints are not of a fixed size and we have an architect role to ensure conceptual integrity (Brooks, 1995) and alignment and synergies with Ono.CDI (Ono Content Driven Infrastructure), our corporate software development framework.

We calculate the size of the sprint according to the commitments established with the clients. However, we always work actively with the clients to keep the sprints shorter than six weeks. Ideally, and on the average, the sprints have three weeks duration.

After sprint is finished, a User Acceptance Test (UAT) with the client area is performed. In this test some minor issues may arise, so we always plan some days in our schedule to fix these minor issues. After the UAT is passed and the fixes are approved we deliver the product of the iteration.

Deliverables Planning: Technology for the Masses

HR and IT established to policy of "*Deliver value to 4980 employees first and later to the remaining 20*". This was our guiding metaphor (Nonaka & Takeuchi, 1995; Beck, 1999) and means that we work to deliver functionality to all the company first (the front-end of the application) and leave the detailed back-end operations for later iterations.

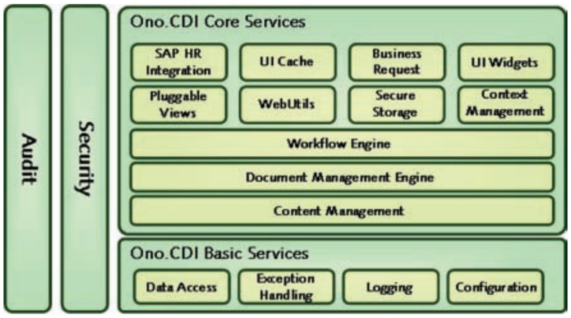
The following example illustrates the idea: we focused on creating client applications with very clear and crisp user interfaces to deliver good tools to all the employees in the company for going through the employee life-cycle processes. This eliminated the physical sheet of paper, the phone calls, and the ambiguities in the process, improving the operations of all the hiring managers and organizational unit managers in the company (and potentially of any employee in the company). However, in the first versions the back-end tools for the HR team where less sophisticated since we used all our resources for providing value to the biggest number of users.

Technology Planning: Leveraging In-House IT Assets

In order to create a reliable and fully functional tool with a low budget and fast delivery we leveraged Ono.CDI (Ono Content Driven Infrastructure Framework), our corporate software development framework for intranet based applications. Ono.CDI contains a set of tools and engines that provide core and basic services (Figure 2) that includes a Workflow Engine, Document Management Engine, Business Request Framework, and Caching Engine (Welicki 2006; Welicki & Sanjuan, 2007). It has crosscutting Security and Audit modules that ensure that applications complain with ONO's IT security policies and with legal audit requirements.

Ono.CDI also includes prescriptive architectural guidelines and blueprints that govern the architecture of ONO's intranet applications. Therefore the application is completely aligned with ONO's development policies lowering its technology transfer and maintenance cost (the maintenance and the development team are formed by different people) and ensuring a quality minimum based proven architectural and design patterns (Fowler, 2002; Gamma, Helm, Johnson

Figure 4. ONO's development framework high level architectural view



& Vlissides, 1995) and development practices.

Financial Planning: More with Less

One of the main goals of the project was delivering within a low budget but still with high level of functionality and quality. On top of our deliverables and technology planning, we created a financial plan to make our developments feasible on time and on schedule.

Our existing software and hardware corporate assets (Ono.CDI development framework and Ono's Intranet deployment infrastructure) set the tooling and deployment costs to the minimum (we where working on proven, reliable, and well-known-to-us components and deploying to a controlled and well known production environment). This also saved us from acquiring new licenses and/or buying new products, since we where building upon (reusing) our in-house IT assets (software and hardware).

The iterative incremental plan allowed us to get a tighter control on budget, having a revision stage at the end of each iteration. Therefore we didn't pay upfront for something that we couldn't plan in advance and made a more efficient use of money, spending smaller amounts in exactly what we need when we need it.

Unfortunately we cannot disclose economic information (prices of products and services) from our partners and supplier proposals. However, what we can certainly state is that we've built our system within a range of 12.5% and 27% (approximate) of the cost the proposals that we had received.

The HR Workflow System

The result of the process is the HR Workflow System that provides support for the employee life-cycle management processes. In a previous section we established a set of requirements that needed to be fulfilled by the system. Following, we will explain how these requirements have been met by the tool.

HR budget control. The system provides a detailed HR budget control. It has been designed and built to keep track of the budget of each organizational unit on a process instance basis. For example, when a manager requests HR to hire a new employee the system checks if his area is above or below its headcount budget. If the area is above its headcount budget the request is annotated with special information (as shown in Figure 5) in order to make this situation easily noticeable to the rest of the participants in the flow. The application also includes reports to provide the HR experts and the upper management with high level real-time views of the overall HR budget evolution in the organization.

Support for the approval workflow. The system used ONO's Workflow Engine capabilities to model the approval workflows. A workflow definition has been created for each of the flows associated with each type of employee life-cycle process (hiring, change of working conditions, and dismissal). Figure 3 (before in this paper) shows the flows for hiring and dismissing employees are shown. Figure 6 shows the flow for changing the conditions of an existing employee within the company (this flow is more complex than the other, with more participants and business rules).

Enabling collaborative work. The HR Workflow System notifies each employee of new events via e-mail whenever a process needs his partici-

Figure 5. Fragment of the "hiring request" screen. Notice how the headcount indicators ("HC presupuestado" and "HC real" fields) are highlighted in red. This means that this request is above the headcount of the requesting organizational unit

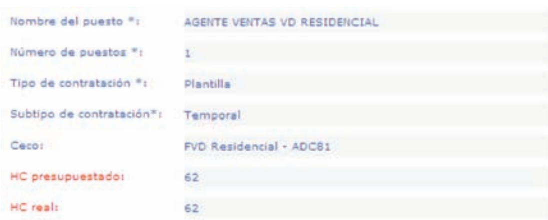


Figure 6. Change conditions of employee flow (promotions, change of salaries, change of departments,change of location, etc.)

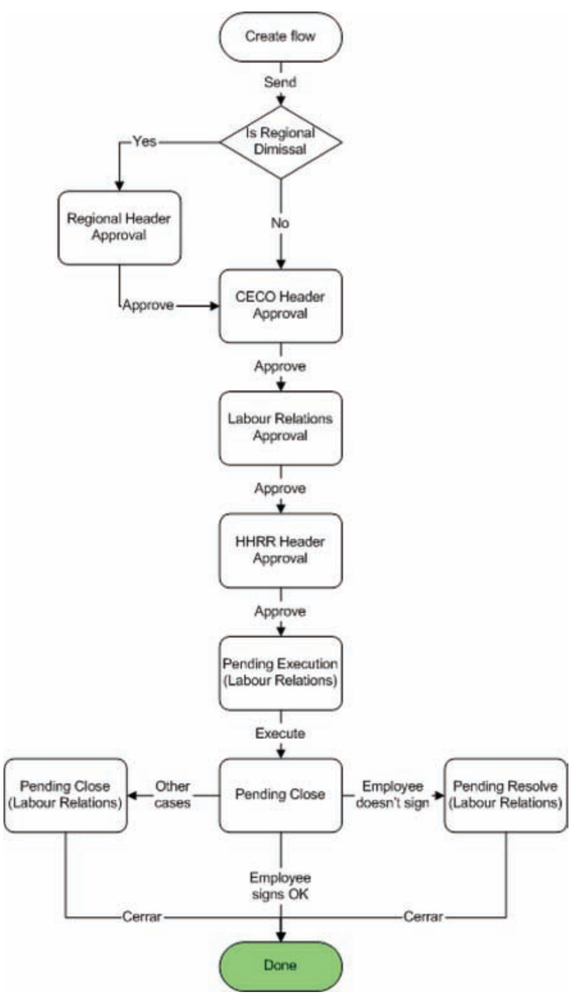

pation. This enhances the users experience since the users don't need to be polling the application periodically to check if there is something that requires their attention. Additionally, the system implements an "Inbox" metaphor (similar to the one used in the e-mail systems) that gathers the requests that need participation of the user. When a user enters in the application his inbox is displayed. Additionally a summary of it (Figure 7) is present during all his session within the application.

Automatic reporting. The system generates automatically the necessary reports for HR control and for the upper management control. They are generated dynamically and can be requested at any moment providing an up-to-date picture of the overall active employee life-cycle processes in the organization.

Traceability and auditability. Every action in the approval workflow of the employee life-cycle process instances is recorded in a history log that is displayed within each process instance (Figure 8). Additionally, access information is recorded but not shown (this is used for privacy and access control audits)

Reducing manual work. All the notifications to participants, reporting, and archival of finished processes is done automatically, eliminating the most tedious and error prone manual tasks.

Input consistency. The input screens reduce the work to be done by the users. Each participant only needs to complete a very concrete (and ideally small amount of) information in each step of the flow. The employee and organizational related information is extracted directly from ONO's IT infrastructure, and the rest of the fields are parameterized lists (whenever is possible) simplifying considerably the creation of new requests (Figure 9).

Reduce bottlenecks in the processes. The application provides "delegation" functionality that allows an employee to "delegate" in another employee his functions. There are also "super-users" (HR members) that can act in any request at any time. Therefore, except in the case rare

Figure 7. Inbox summary. This widget is displayed in the left menu bar of the screen and is always visible. This widget shows the total number of requests of each type that requires the participation of the logged user. When the user clicks in any of the request types the complete inbox is displayed

Figure 8. History of a process. Each action performed on the request is recorded (including the execution user, date, target state, and observations)

Figure 9. Input screen for working conditions change. After an employee is selected (first field) all his information is retrieved from the corporate SAP HR database and displayed in read only fields. The remaining input fields in the form are parameterized drop down lists

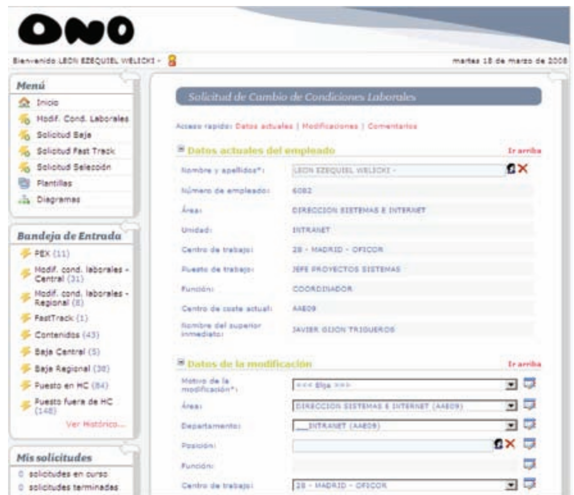

Figure 10. UI consistency and simplicity: the HR Workflow System (right side of the figure) is similar to the corporate intranet (left side of the figure)

situations that need a careful analysis of a senior manager, no employee is a bottleneck for a process instance in the system.

Ease of use and far reach. We based our user interface (UI) in our corporate Intranet (OnoNET) that is well known among all ONO employees (Figure 10). We also used all the UI widgets of our development framework having consistency with the existing applications in the intranet. The use of web-based technologies simplifies the deployment and reach of the tool: any user with a browser can access and use the HR Workflow System. Our UI foundation follows the usability guidelines presented in Nielsen (1999) and Krug (2000).

Achieving Strong Employee Life-Cycle Management

ONO HR Workflow System provides support for automated, formally defined, input consistent, predictable, and repeatable employee process life-cycle management. Additionally, all reporting is done automatically at run-time, eliminating manual consolidations.

Another very important outcome is that since we have automated the consolidation of information a single repository for employee corporate information can be easily established and feed with the results of the processes. This repository (shown in Figure 11 as "Employees Digital Identity Database") is an authoritative up-to-date source of information for all other e-HRM applications, avoiding the need of manual or semi formal small integrations, enhancing the operational quality and information of eHRM within the organization. As soon as a change in an employee's information or hierarchical structure is introduced in the system (through the execution of an instance of an employee life-cycle process) it is available to all applications without the need of performing any manual integration task. Moreover, employee and organizational concepts are normalized within all eHRM applications in the company allowing easier integrations (they all share the same employee and organizational abstractions).

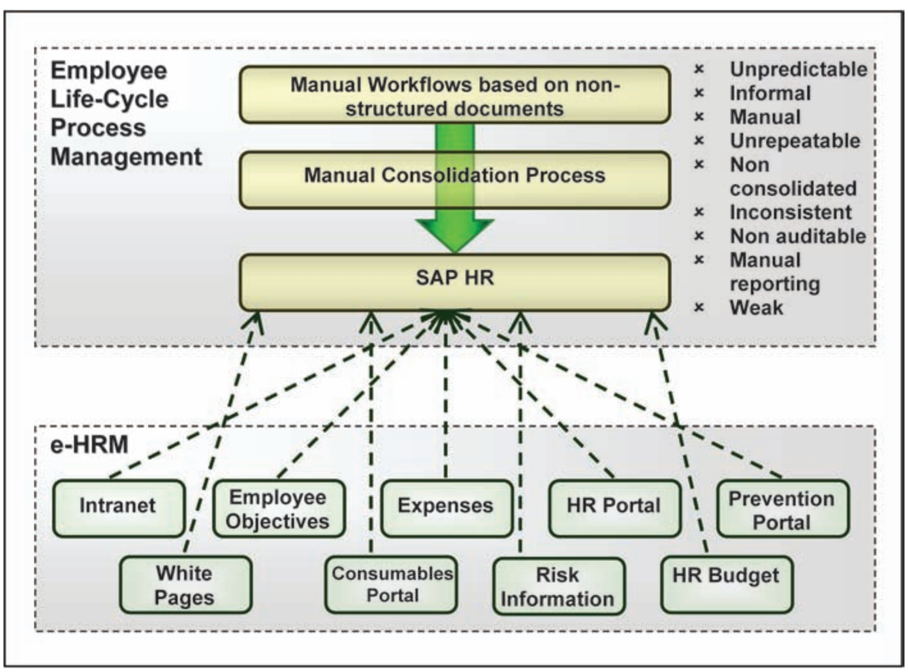
Ono HR Workflow System has all the necessary features to provide strong employee life-cycle process management (Figure 11).

Future Improvements

We improved and normalized the employee life-cycle support significantly, but our work isn't finished yet. Currently, we are working on the following enhancements to the system:

- **Dynamic HR budget with SAP Business Warehouse:** implement SAP Business Information Warehouse (SAP Corporation,

Figure 11. Ono's current "strong employee life-cycle process" model. The process instances go through a formal approval workflow in a web-based application. The results of the processes feed ONO's SAP HR and in return this feeds a centralized corporate information (identity) repository. Applications have a unique source of information for organizational data, reducing the integration and maintenance burden within the whole e-HRM ecosystem



2008) to provide dynamic and up-to-date information on the headcount budget. Currently the budget is loaded in the system upon HR's request. Using SAP's Business Intelligence suite can provide also analytical capabilities when looking at the future (e.g. forecasting budgets) and when looking at the past (e.g. analyzing real versus forecasted)

- **Improving the support for the selection process:** currently some parts of the selection process (for hiring new employees) are done offline. The system doesn't provide support for managing the interviews with candidates and managing offer letters (this two issues need very special attention of ONO's legal department according to Spanish laws on information protection).
- **Automatic creation and archival of formal letters:** Automatically create formal letters within each process and archive them in the process instance. This will eliminate the remaining paperwork associated with the process instances.

CONCLUSION

The workflow system has been in production for more than a year. It has successfully managed a big number of requests (we cannot disclose that information here), bringing reliability, traceability, and audatibility to the employee life-cycle management processes. It has become one of the core systems for supporting HR operations.

The resolution of each employee life-cycle process went down from weeks (in the manual case) to just days or hours (according the complexity of the request). Each participant in the process has to just perform a very concrete action and work with very concrete set of data. Additionally, he is notified via mail every time he needs to perform an action on a request.

Reporting is done automatically. The HR staff doesn't have to spend time on creating reports and the upper management has real-time in information on the on-going employee life-cycle processes.

Everyone in the company knows the processes (they are unambiguous, well documented, and accessible to everyone in the organization) and the processes are always the same for every employee in the organization. They are no longer dependent on the participants. At the same time the processes model the reality of our company and had been tailored to provide as much value as possible to it.

We could summarize the main benefits of the system in these three items:

1. **Reliable information:** The data sources are accurate based on normalized input and each process instance is auditable.
2. **Agile information:** The employees are notified only when they have to participate in a flow eliminating unnecessary and unproductive "polling" in an application.
3. **Improved information management:** The employee process life-cycle processes information is centralized, easy to access, and normalized, making it easy to know about the state of any on going or finished process in a uniform and simple way.

ABSTRACT

Brazilian companies are increasingly turning to Web-based corporate training by virtue of the fact that they need to train their employees within tight budget constraints in a country of continental dimensions. However, most of these companies do not know what the critical success factors in these endeavors are. Therefore, this article seeks to investigate some key success factors associated with such digital enterprises. In order to achieve this, the multiple case study method is used, whereby two cases, both conducted within the same Brazilian company, leading to opposite outcomes—a success and a failure—are analyzed in depth. The conclusions reached in this article were that goal orientation, source of motivation, and metacognitive support were the three critical dimensions in these two Web-based corporate training programs under analysis. Lastly, some managerial implications of these results are outlined.

INTRODUCTION

Nowadays, market dynamics are becoming increasingly intense due to new strategic orientations and the pressing need for businesses to adapt themselves to new business models and regulatory frameworks. For this reason, it is of paramount importance for companies to become agile, as well as achieve low costs and high returns on investment associated with their employee training programs. On the other hand, the increasing speed of obsolescence in training content, plus the high costs of face-to-face training programs, as well as the logistic hurdles linked with their deployment—mainly in firms operating in countries of continental dimensions (like Brazil)—are major barriers to the implementation of such face-to-face training programs.

Another aspect is that information technology (IT) is changing the way people search, locate, access, and retrieve available knowledge, as well as altering the learning process and the way training is conducted (Hodgins, 2000). While employees take charge of their own learning process and professional development, the employers face new challenges in training and retaining teams with in-depth knowledge about their business (Hodgins, 2000).

It is in this context of rapid change, with massive information loads and the search for training programs, that Web-based corporate distance training comes into its own. Information technology can solve most of the problems associated with the hitherto existing employee training undertakings, enabling the implementation of corporate distance training programs (Rosemberg, 2001).

Despite being a key factor for developing feasible training programs, information technology per se is not a guarantee of success for these endeavors. Most of the time, it must be linked to pedagogical and didactical issues related to them. The specific characteristics of each training program must be analyzed in depth and considered as relevant as the implementation costs throughout the decision-making process (Clark, 1983).

The structuring of Web-based training programs is no easy task, as according to several scholars, various critical success factors must be taken into consideration (see, for instance, Carey, Mitchell, Peerenboom, & Lytwyn, 1998; Penuel & Roschelle, 1999). In line with this, this article seeks to investigate what these critical factors are through the analysis of two distinct Web-based training programs conducted within the same Brazilian company. Hence, the research question in this article is: "What are the critical success factors associated with the implementation of these two Web-based corporate training programs?"

In order to achieve this goal, this work is structured as follows. First, the first section addresses the theoretical references used in this article. Then, the research method is outlined. After that, the two cases under analysis are described, and in the next section, the results accrued from them are compared. In the last section, the authors present some final comments.

Theoretical References

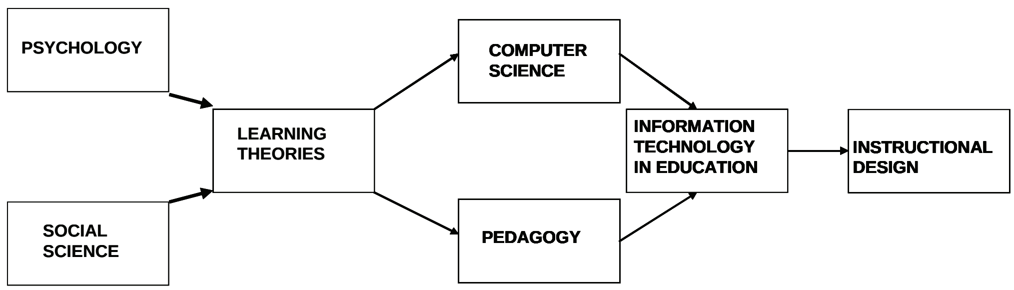
According to Wilhelmsem (2005) and Huitt and Hummel (2003), there are four knowledge fields associated with distance training, namely psychology, social science, pedagogy, and computer science. Figure 1 depicts how these four areas are interlinked, pointing to the crucial importance of social science and psychology—and learning theories—as the theoretical support for the areas of pedagogy and computer science, in order to enable the development of an instructional design aiming to apply information technology in education.

Behaviorism, cognitivism, and constructivism are all theories addressing the learning process, as well as the nature of knowledge and its main facets (Wilhelmsem, 2005). For behaviorists, knowledge is characterized as a passive process. Learning is explained without reference to the mental processes, as its focus is on observable behavior and in the way individuals adapt themselves to the environment. For cognitivists, the learning process molds the individual's mental construction. Finally, for constructivists, knowledge is seen as relative and socially built, varying according to time and space (Wilhelmsem, 2005).

Behaviorism

For behaviorists, psychology is the science of behavior, rather than the science of the mind. Behavior is correlated to external factors—the environment—instead of internal factors (Campos, 1982). The theory of classic conditioning, developed by Ivan Petrovich Pavlov (1849–1939), has a psychologi-

Figure 1. The creation process of instructional design in distance training (adapted from Wilhelmsem, 2005)



cal basis, as learning is developed via the linkage between situation, stimulus, and reaction. As the organism stores a repository of answers, trends, and reactions, it is able to act and produce an answer through an adequate natural and not conditioned stimulus (Campos, 1982).

Edward Lee Thorndike (1874-1949), in his connectionist learning theory, pointed out that the connection arises from the association between the impression of the senses and the impulses for action, namely from the linkage between the stimulus and the corresponding answer (Reinemeyer, 1999). Thorndike defined psychology as the science that studies the intellect, the behavior, and the characteristics of animals as well as human beings. Human education is concentrated on the emergence of certain changes in intellect, characteristics, and behavior in a composition based on four topics: objective, content, meaning, and method (Thorndike, 1911).

John B. Watson (1878–1958) presented a work in 1912 that is the basis for the development of behaviorism. He stated that humans and animals are complex machines that react to situations based on conditioned experiences, rather than on hereditary factors (Watson, 1929).

For Skinner (1904–1990), man is neutral and passive with behavior that can be described from a mechanistic standpoint. In his theory of operant conditioning, it is important that the stimulus follows the answer, which is named "reinforcement" by Skinner (Graham, 2005). Skinner stated that tools must be used to control the human learning process better. Thus, he recommended the use of programmed teaching, namely a process that allows the students to go further via a string of stages developed according to the student's own pace and reinforced immediately after each stage (Campos, 1982).

Cognitivism

In order to explain the development of cognitive processes, Piaget (1896–1980) revealed how organisms adapt themselves to their environments. This adaptation to the environment is controlled by the mental organization, namely schemes, which individuals use to represent a word and an established action. This adaptation is ruled by biological impulses in order to achieve equilibrium between the schemes and the environment (Huitt & Hummel, 2003).

Through his psychology of development of the intelligence, Piaget established a theory about the four stages whereby individuals—from birth to adulthood—acquire skills for logical reasoning. The rationale in this theory is that thinking is not the automatic outcome of reflections and intuitions, but rather a flexible operation developed by processes of trial and error (Piaget, 1964).

On the other hand, according to Lev Vygotsky (1896–1934), the impact of the external world on individuals' internal world, based on their interaction with reality, must be examined. Thus, social interaction is of paramount importance in a person's cognitive development. According to Vygotsky's principles, the origins of the changes that occur in these persons lie in their interaction with society, culture, and their particular story, that is, in the social theory of learning (Huitt & Hummel, 2003).

To the cognitivists, the thinking and previous knowledge of the students must be taken into account in the development of a course syllabus. Moreover, for them, the students move to new learning objectives in an increasing order of complexity, from the simpler to the more complex (Campos, Rocha, & Campos, 1998).

Constructivism

Studies in constructivist theory started with Jean Piaget, based on both an epistemological focus and an interdisciplinary perspective. His main question was: "How does one go from less developed knowledge to more developed knowledge?" A theory was then elaborated addressing the cognitive mechanisms of human beings (Huitt & Hummel, 2003).

For Piaget, intelligence is an active and organized assimilation process. When exposed to a challenge or stimulus, the individual experiences a disturbance in intellectual equilibrium, becomes curious, defied, and motivated. Then, through assimilation and accommodation, the individual recovers the former equilibrium, which is always dynamic as enabled by physical and/or mental actions. This equilibrium process is the central concept in Piaget's constructivist theory (Wilhemsen, 2005).

Lev Vygostky is another person who effectively contributed to building the conceptual basis of constructivism. He stressed the importance of language as a thinking tool, enabling the restructuring of several psychological functions, such as memory, attention, and the development of concepts. In this way, language acts decisively on the structure of thinking and is the basic tool for the construction of knowledge (Huitt, 2003).

Vygotsky (1935) also argued that knowledge is built from the action of individuals vis-à-vis reality and that individuals are not just active persons but also interactive and social beings, as they develop their knowledge, which is in turn developed by intra and interpersonal relationships. This process goes from a social dimension based on interpersonal links to an internal dimension based on intrapersonal links, such that the subjects effectively take part in the construction of their own culture and story, which changes them while also provoking changes in the individuals who interact with them.

Based on Piaget's research, Bruner (1985) argued that learning is an active process, whereby students build new ideas and concepts based on their own knowledge, select and transform information, develop hypotheses, and make decisions in order to establish their own cognitive structure (Huitt, 2003).

Teaching and Learning Theories

The constructivist approach requires that the aims and targets of training must be clearly defined, as well as the process for measuring the outcomes accrued from it (Mergel, 2005). On the other hand, a course based on the cognitivist model must consider the lessons accrued from the student's previous knowledge so as to achieve new learning objectives. This paradigm does not consider that the students will have the same prior experiences they once had, nor that they will learn in the same way they once did (Houser, 2005).

There are concepts that are common to both constructivism and cognitivism, since both are based on the assumption that new knowledge is built upon prior knowledge. For the constructivists, the student rather than the content, program format, and instructor is emphasized in a learning process. The latter is no longer the center of the learning process, as the students play this role (Wilson, Jonassen, & Cole, 1993).

In constructivism, knowledge is perceived as relative—nothing is absolute—varying according to time and space (Wilhelmsen, Stein, & Øyvind, 2005). According to Jonassen (1981), the cognitive tools are mental and computational devices that support, lead, and broaden the thinking process. In other words, the mind is in charge of knowledge acquisition via a linked cognitive process, and information plays the role of a stimulus that is perceived and recorded in the mind.

Instructional Design

Instructional design is the association of distinct learning theories with the development of pedagogical content, conveying to a certain training program. Its main objective is the application of learning theories in order to set up a concrete path that enables learning processes (Wilson et al., 1993). Rieber (1992) argues that there is no conflict between instructivism—based on behaviorism—and constructivism, such that training can incorporate features accrued from both paradigms without conflict. Rieber (1992) also states that the basic principles for the development of instructional design should include setting up the challenge to be proposed to the student correctly, making it neither too easy nor too difficult. It should also offer elements of surprise in order to arouse the curiosity of the student, as well as provide a context that intrinsically supports motivation and autoregulation of the learning process.

Malone (1999) argues that three characteristics increase the motivation and autoregulation of the student. The first is to provide a context whereby the students can enter into dialogue with their imagination and develop a personal state of fascination and intrigue. The second is to develop a context that arouses the students' curiosity, and the third is to set up a pattern that allows the students to travel from the "known to the unknown."

Assessment of Web-Based Corporate Training Programs

In many cases, the departments of a company need to develop corporate distance training programs via the Web. More often than not, these programs are oriented by technical imperatives, namely the obligation to use Internet technology. In some organizations, the Web-based training programs were designed specifically to justify the costs of the corporate intranet (Powell, 2000). However, the use of technology per se cannot be considered a justification for implementing any kind of training, as stated by Rosemberg (2001), Bregman and Jacobsen (2000), Bates (1995), and Kay (1970), to name a few.

In order to develop a comparative analysis between Web-based training programs, it is necessary to adopt a specific framework. In this article, the model proposed by Reeves and Reeves (1997) will be applied to identify and evaluate the distinct dimensions involved in Web-based training as explained later. This model has applications in the research, implementation, and evaluation of Web-based training programs such as those analyzed in this article.

It is important to stress that the model developed by Reeves and Reeves (1997) does not propose to evaluate either the outcome of a Web-based training program, or its success or failure. Indeed, the overriding purpose of this model is to assess the different aspects and facets of this kind of program (Reeves, 1997). The adopted model includes 10 dimensions of interactive learning on the World Wide Web, namely: (1) pedagogical philosophy, (2) learning theory, (3) goal orientation, (4) task orientation, (5) source of motivation, (6) teacher role, (7) metacognitive support, (8) collaborative learning, (9) cultural sensitivity, and (10) structural flexibility.

Each of the 10 dimensions in this model is presented as a two-ended continuum with contrasting values at either end. Needless to say, the world is rarely dichotomous, and there is more complexity involved in training than any of these dimensions suggest. However, the individual dimensions themselves are not as important as the interplay among the 10 dimensions that represent the instructional designs of various Web-based training programs. These dimensions are detailed below.

a. **Pedagogical Philosophy (Instructivist <=> Constructivist):** The debate over instructivist and constructivist approaches to teaching and learning persists to this day (Kafai & Resnick, 1996). Instructivists stress the importance of objectives that exist separately from the learner. Little emphasis is placed on learners themselves, who are viewed as passive recipients of instructions or treated as empty vessels to be filled with learning (Sherry, 1996). By contrast, constructivists emphasize the primacy of the learner's intentions, experience, and cognitive strategies. According to constructivists, learners construct different cognitive structures based upon their previous knowledge and what they experience in different learning environments. It is of paramount importance for constructivists that learning environments be as rich and diverse as possible. Instead of an empty vessel, the learner is regarded as an individual replete with pre-existing motivations, experiences, aptitudes, and knowledge. Tasks to be accomplished and problems to be solved must have personal relevance to the learner. The constructivists believe that what we know is constructed—both individually and socially—based on prior experience.

b. **Learning Theory (Behavioral <=> Cognitive):** According to behaviorists, the critical factor in learning is observable behavior, and instruction involves shaping desirable behavior through the arrangement of stimuli, responses, feedback, and reinforcement. A stimulus is provided (e.g., a short presentation of content), then a response is elicited—often via a question. Feedback is given as to the accuracy of the response, and positive reinforcement is given for accurate responses. Inaccurate responses result in a repetition of the original stimulus, and the cycle begins again. Cognitive psychologists place more emphasis on internal mental states than on behavior. Cognitive taxonomy of internal learning states includes simple propositions, schema, rules, skills, mental models, and so forth. They claim that a variety of strategies—including memorization, direct instruction, deduction, drill and practice, and induction—are required in any learning environment, depending upon the type of knowledge to be created by the learner.

c. **Goal Orientation (Sharp <=> Broad):** The goals for education and training can range from sharply focused goals to general higher order goals. Hence, the goal orientation of Web-based training systems varies in degree of focus from sharp to broad (Cole, 1992).

d. **Task Orientation (Academic <=> Authentic):** The context of learning is enormously important to adults (Giardina, Oubenaissa, & Bhattacharya, 2002; Merriam, 1993). Academic design depends heavily on having the learners carry out traditional academic exercises, whereas authentic design engages adults in practical activities such as preparing job applications, thereby situating practice and feedback within realistic scenarios. If knowledge, skills, and attitudes are learned in a practical context, they will be used in that context in similar situations.

e. **Source of Motivation (Extrinsic <=> Intrinsic):** Motivation is a primary factor in any theory or model of learning (Amabile, 1993). All new educational technology promises to be intrinsically motivating. This dimension ranges from extrinsic (i.e., outside the learning environment) to intrinsic (i.e., integral to the learning environment). Motivation instruction is intrinsically elusive, irrespective of the delivery system.

f. **Teacher Role (Didactic <=> Facilitative):** The teacher role continuum ranges from didactic to facilitative. In the former role, the teacher presents information and asks learners to memorize information and recall it later in tests. The latter role assigns cognitive responsibility to the learners, for them to be responsible for recognizing and judging patterns of information, organizing data, constructing alternative perspectives, and presenting new knowledge in meaningful ways with the teachers as tutors of this process.

g. **Metacognitive Support (Unsupported <=> Integrated):** Metacognition refers to a learner's awareness of objectives, ability to plan and evaluate learning strategies, and capacity to monitor progress and adjust learning behavior to accommodate needs (Flavell, 1979). The metacognitive support dimension is unsupported at one end of the continuum and integrated at the other. Recapitulation of the students' strategies at any point in the problem-solving process, as well as construction of Web-based portfolios (Nevado, Basso, & Menezes, 2004), are examples of how support for reflection, and metacognition might be provided in Web-based corporate training.

h. **Collaborative Learning Strategies (Unsupported <=> Integral):** The collaborative learning dimension ranges from a complete lack of support for collaboration to the inclusion of collaborative learning as an integral feature. Cooperative and collaborative learning refers to instructional methods in which learners work together in pairs or small groups to accomplish shared goals (Kirschner, Stribos, Karel Kreijns, & Beers, 2004).

i. **Cultural Sensitivity (Insensitive <=> Respectful):** All instructional systems have cultural implications. In an insensitive approach the training is developed irrespective of the culture and diversity of the learners it is intended to address. On the other hand, a respectful approach is based on the diversity in the populations in which the system will be used so that the overall learning environment is enhanced. It is unlikely that Web-based training can be designed to adapt to every cultural norm, but sites should be designed to be as culturally sensitive as possible (Brown & Voltz, 2005).

j. **Structural Flexibility (Fixed <=> Open):** "Fixed" systems, still dominant in education, are usually limited to specific places, for example, a classroom or laboratory, at specific times, for example, 50-minute class period. Irrespective of time and/or location constraints the learner can use "open" systems. The World Wide Web provides opportunities for more asynchronous (open) learning, although some Web-based learning tools are temporally fixed (synchronous), such as chats, video-conferences, and so forth.

Table 1 depicts the 10 dimensions defined for analyzing Web-based training programs, as supported by Reeves and Reeves (1997). For each dimension (in the central column of the table), the opposite poles of the adopted ratio scale (ranging from 0 to 10) are described and their meanings explained.

Research Method

The multiple case study method as described by Yin (1994) was adopted in this research, in which two Web-based distance-training programs developed within the same Brazilian company were analyzed in-depth. Case studies are particularly suitable for answering "how" and "why" questions, and are ideal for generating and building theory in an area where little data or theory exists (Yin, 1994), as in this knowledge field. It also enables researchers to use "controlled opportunism" to respond flexibly to new discoveries made while collecting new data

Table 1. Dimensions to evaluate the characteristics of Web-based distance training (adapted from Martin, 1998, and Joia, 2001)

0←	Dimension	→10
Instructivist Knowledge is imparted by the instructor	**Pedagogical Philosophy** 0—10	**Constructivist** Knowledge is constructed—both individually and socially—by the students
Behavioral Emphasis on observable behavior	**Learning Theory** 0–10	**Cognitive** Emphasis on internal mental states
Sharp Direct instruction focusing on desired behavior	**Goal Orientation** 0–10	**Broad** Simulations encompassing more than just a solution for the problem
Academic Emphasis on traditional academic exercises	**Task Orientation** 0–10	**Authentic** Emphasis on practical activities
Extrinsic Motivation lies outside the learning environment	**Source of Motivation** 0–10	**Intrinsic** Motivation lies in the student and the learning environment
Didactic The teacher is considered to be a knowledge repository	**Teacher Role** 0–10	**Facilitative** The teacher is a mentor and tutor for the students
Unsupported There are no student progress tracking mechanisms or adjustments to individual needs	**Metacognitive Support** 0–10	**Integrated** Student progress tracking mechanisms are implemented, as well as adjustments to individual needs
Unsupported Students work alone	**Collaborative Learning** 0–10	**Integrated** Students work together in pairs or in small groups
Insensitive Training is prepared regardless of the culture and diversity of the learners it seeks to address	**Cultural Sensitivity** 0–10	**Respectful** Training is based on the diversity of the populations where the system will be used
Fixed Program limited to specific places at specific times	**Structural Flexibility** 0–10	**Open** Program independent of time and/or location constraints

(Eisenhardt, 1994), as was done and is presented below in this work.

Notwithstanding having a major exploratory facet, this study also presents explanatory characteristics, as a causal relationship between the dimensions of the programs analyzed (Reeves & Reeves, 1997) and the respective outcomes are pursued. Yin (1994, p. 46) argues that in the multiple case study method, each case must be carefully selected, so as to generate either similar or opposing results. In line with this, a Brazilian company was chosen (the identity of which is confidential), and two Web-based training programs it developed and staged were selected, each one generating contrasting final results.

The first case—hereinafter referred to as Program A—was considered a success as it achieved its main objectives. The second case—hereinafter named Program B—developed by the same company, was considered a failure, as most of its targets were not accomplished. In order to comply with Yin's (1994) ideas necessary to validate this case study method, the following four issues were cautiously taken into consideration, namely: construction validity, internal validity, external validity, and reliability, as revealed below.

Construct Validity

In order to validate the "key success factors in Web-based corporate training" construct, multiple data sources were used, and also a chain of evidence related to research questions was pursued. The existing records associated with these projects were analyzed in-depth. The managers of both programs were located in the company and interviewed—there was a single manager for the first case (Program A) and two managers for the second case (Program B).

Questionnaires were circulated among the training users. These questionnaires sought to establish their perceptions relating to the 10 dimensions proposed by the Reeves and Reeves (1997) model. In addition to this, the users also revealed their perceptions about the rate of accomplishment of objectives of each program vis-à-vis the actual objectives proposed for the programs in their initial designs.

In line with the ideas proposed by Reeves and Reeves (1997), the minimum value of the scale (0) indicates that a dimension is fully aligned with the instructivist/behaviorist paradigm, whereas the maximum value of the same scale (10) proves that a dimension is fully aligned with the constructivist/cognitivist paradigm (Joia, 2001). Moreover, the maximum value of the scale (10) associated with the "accomplishment of training objectives" indicates user perception of complete success for the training program, whereas the minimum value (0) points to user perception of total failure for the training program. The aforementioned questionnaires were answered by 32 users of the first case analyzed (Program A) and 31 users of the second case (Program B).

Internal Validity

With a clear exploratory approach, this work addressed some explanatory elements used to verify the possible causal effects between the dimensions of the theoretical model and the training outcomes. This was done to support the internal validity of this research, in accordance with the recommendations of Morra and Friedlander (1999).

The first analysis conducted sought to compare user perceptions about the rate of accomplishment of objectives for the two programs, in order to verify whether or not the respective average of these grades could be considered statistically distinct. Once the difference between user perceptions regarding the rate of accomplishment of objectives for each program was recorded, a statistical comparison of user perception averages associated with each dimension of the theoretical model applied was performed. Since it had already been seen that the two programs presented statistical differences with respect to their outcomes, namely success and failure, the dimensions that did not present statistically significant differences within the two programs were discarded as not being critical success factors.

Thus, from this prior comparison, two dimensions of the Reeves and Reeves (1997) model were removed, leaving eight dimensions to be analyzed further. In order to achieve this, a multivariate linear regression was used, where the rate of accomplishment of training objectives was the dependent variable while the grades given by the users to each of the eight remaining dimensions of the model served as the independent variables. The significance level of each coefficient associated with these dimensions (independent variables) was then calculated and analyzed, while the dimensions whose coefficients did not present evidence of linear correlation with the dependent variable (accomplishment of objectives) were discarded.

The above procedure highlighted three dimensions, which could be considered critical success factors for the training programs analyzed.

Lastly, as a final quantitative validation, a simple linear regression was performed on each dimension removed from the study for not being related to the accomplishment of training objectives. The simple regressions supported that these factors did not possess a fair linear correlation with the objectives of the training programs.

External Validity

The external validity addresses whether or not the findings accrued from this research can be generalized for other similar cases not yet studied (Yin, 1994, p. 35). This work investigated the same factors related to two distinct cases developed by the same company so as to support the external validity of this research, enabling the results to be applied in other cases within the same firm analyzed.

Reliability

A protocol for documentation of the adopted procedures was developed to guarantee the reliability of this study. A digital data repository was also created to store all information gathered during the data collection stage. This repository stores the data set acquired during the field research for this investigation, as well as all the results accrued from the statistical analysis performed.

CASE DESCRIPTION

The Company

The company under analysis is a major Brazilian firm in the information technology industry. It has more than 30,000 employees with offices throughout Brazil.[1] In 2003, the company posted total revenue of US$865 million and net income of US$76 million. Due to its nationwide presence, this company faces an ongoing challenge to implement face-to-face corporate training programs, due to budget constraints. So, it is in this context that the two training programs, namely Program A and Program B were envisaged and implemented. The name of the company, as well as further details about it, are kept confidential, as agreed with its top executives.

Program A

Program A, considered a successful case by the company, is a mandatory corporate distance training program for all managers, namely its main target audience. Any employee who is promoted to a managerial function is obliged to take this course within a maximum timeframe of one year.

This training program lasts 9 months and consists of three distinct stages that encompass distance and face-to-face training. The focus of this program lies in the development of leadership skills. Accordingly, the following issues are addressed: the attributes that make an effective leader; the different kinds of leadership styles that are best used under certain conditions; the various theories of leadership practice and the pros and cons of each; and the leadership responsibilities related to administrative and management tasks.

The training program is based on the premise that, rather than being an isolated event, learning is a continuous process throughout the professional's lifetime. Program A uses several information technology tools, such as intranet that is heavily deployed to provide information considered essential for the managers of the company.

Stage I of this program (prelearning laboratory) is developed online in a distance-based training format. This stage lasts from 5 to 6 months and is an individual activity that demands between 48 and 56 hours of study.

Stage II of this program (learning laboratory) is a face-to-face experience lasting 5 days. The professionals must have successfully completed Stage I before embarking on this second stage. This learning laboratory takes place in the Global Learning Center of the company, in the city of São Paulo.

Stage III of this program (postlearning laboratory), like Stage I, is developed on a distance-training basis. This stage focuses on collaborative learning via the company's intranet, as well as public forums and tools like instant messaging.

Throughout the duration of the course, a mediator is previously assigned and available to take part in the program, both in person and online, in order to resolve any doubts the professionals may have, to supply the students with suggestions, and to help them solve general problems.

According to an interview with the manager of Program A, this program is considered a success, having fully achieved its targets. Furthermore, 32 users of Program A, who attended the program during 2005, answered the questionnaire developed for this research and evaluated their participation on this training program as a highly positive experience (average of 8.5 and standard deviation of 1.32 on a ratio scale ranging from 0 to 10). Therefore, it may be considered that the objectives were achieved. All of the 32 respondents were managers of the company.

Program B

Program B started at the beginning of 2004, initially as an effort to provide and make information about the company's productive and administrative processes available to employees located in the various offices of the company nationwide. The design and development of the program was organized by the company's IT team, supported by the basic premise of using the corporate intranet to publish all the content considered relevant.

The first version of the program gathered and consolidated the wealth of information about the company's processes already published in the intranet under a single site with a unique index for conducting searches. For this purpose, a team of five employees from two different business units was formed to assist the IT area in the identification and classification of information.

Once the information had been duly identified and classified, the IT area began to configure the program, so as to feature distinct courses categorized by subject. These courses could then be accessed by any employee via the intranet. Consequently, for each course implemented, a program manager was chosen to be in charge of developing the assessment questions (multiple-choice based), having privileged access to the answers given by the students.

After an initial test period—based on just one course developed for a specific group of employees—three distinct courses were made available—two of them focusing on specific working processes of the firm (order fulfillment and customer service), and the third addressing administrative content (employee performance assessment and promotion).

The main target of this training program was to reduce the costs involved in corporate training, as well as to speed up the adaptation and training time for newly hired professionals to become accustomed to the processes used by the organization. After less than one year, having failed to achieve its objectives, the program was redesigned.

Thirty-one users of Program B who attended the program during 2005 answered the questionnaire distributed by the researcher. In essence, they evaluated the experience of taking part in this program as negative since the aims were not achieved (average of 4.52 and standard deviation of 1.15 on a ratio scale ranging from 0 to 10). This evaluation from these employees was tallied with the opinion of the program managers, as they stressed that the objectives of this program were not achieved.

Comparison of Results

Initially, it is necessary to analyze the differences singled out by both the program managers and users concerning the achievement of objectives of the training programs. According to the assessment of the manager of Program A, the objectives of the training were fully achieved, and in his general evaluation, the program was rated as "very good." Conversely, the managers of Program B realized that the main targets of this program were not achieved, which led the program to be redesigned. Thus, according to the managers' perceptions, the difference related to achievement of objectives between the two programs becomes clear.

In order to analyze user perceptions related to the programs, it is necessary to evaluate the difference between the average grades given by the students to each one of the programs. The average user evaluation grade regarding the achievement of objectives in Program A was 8.5 (s=1.32; n=21, on a ratio scale of 0 to 10), whereas the same value concerning Program B was 4.52 (s=1.32; n=32, on a ratio scale of 0 to 10). This difference between the averages seems to tally with the opinion of the program managers. However, it is necessary to apply a statistical test (t-test) to compare the average of each program, so as to establish whether or not they can be considered different according to a statistical level of significance.

Table 2 depicts the results accrued from the comparison of employee evaluation averages related to the achievement of objectives of the training programs. From the results presented in Table 2, it is clear that there is a significant statistical difference between user perception averages related to the achievement of objectives of the training programs ($p < 5\%$). Furthermore, it can be observed that the interval of confidence does not encompass zero; that is, it is all positive. Thus, it is possible to support with a 5% level of significance that the averages are different and the average of Program A is greater than the average of Program B (Sincich, 1995, p. 532). It can be argued that with respect to "achievement of objectives," Program A achieved better results than Program B.

On the basis of this, the factors that influenced these results were researched, based on the theoretical model adopted in this article. Consequently, the evaluation averages of each dimension of the Reeves and Reeves' (1997) model were analyzed in order to find out which ones actually had an impact on the results depicted above. Similarly, the dimensions that presented statistical significant differences in the sample averages for each program were examined, as these are the dimensions that can be considered to be influential in the achievement of objectives of each Web-based corporate training program analyzed. Table 3 compares the averages related to each dimension of the programs under analysis, according to the framework of Reeves and Reeves (1997).

As can be seen in Table 3, there is no difference in the pedagogical philosophy and structural flexibility dimensions in the two cases, with a 5% level of statistical significance ($p>0.05$). Hence, these dimensions can be disregarded as critical success factors in Web-based corporate training. Based on this result, a multiple linear regression between the achievement of objectives (dependent variable) and the eight dimensions that presented significantly distinct averages (independent variables) was run. The intention was to verify which variables could be considered truly influential in the outcomes achieved. It is important to stress

Table 2. Comparison of averages related to "achievement of objectives" according to the users of the training programs

	Levene's Test for Equality of Variances		t-test for Equality of Means						
								95% Confidence Interval of the Difference	
	F	Sig.	T	df	Sig. (2-tailed) (p)	Mean Difference	Std. Error Difference	Lower	Upper
Achievement of Objectives	.202	.655	12.752	61	.000	3.98	.31	3.36	4.61

that this regression seeks to verify the impact of each dimension on the outcomes of the programs under analysis, rather than to predict the outcomes of similar programs based on the dimensions of the model proposed by Reeves and Reeves (1997).

Table 4 depicts the summary of results and the statistical values accrued from this multiple regression. This summary supports the validity of using the eight dimensions of the theoretical model (predictors) to forecast the achievement of objectives for each case studied (in the summary, the "R" column represents the correlation coefficient and the "R Square" column represents the determination coefficient). From these data, it can be argued that nearly 70% (0.675) of the variance of the "achievement of objectives" variable can be explained by the dimensions included in this regression.

After validation of the model, an attempt was made to verify which coefficients, namely the dimensions of the model applied, actually influenced the achievement of objectives of Web-based training programs. Table 5 presents the summary of the statistics related to the coefficients of the regression model. From the results depicted in Table 5, it can be deduced that with a 5% level of significance, the learning theory, task orientation, teacher role, collaborative learning, and cultural sensitivity dimensions did not reveal evidence of any statistically significant linear relationship with "achievement of objectives" (Sig. > .05).

In order to strengthen the results accrued from this multiple linear regression, with respect to the lack of evidence of any linear relationship of the learning theory, task orientation, teacher role, collaborative learning, and cultural sensitivity variables, simple linear regressions of each of these variables vis-à-vis the "achievement of objectives" were performed. Table 6 presents the summary of the results accrued from these five simple regressions, which was drawn up separately from Table 5 to make it easier for the reader to fully understand the influence of each discarded dimension in the "achievement of objectives."

As can be observed from analysis of the correlation coefficient (column "R") and the determination coefficient (column "R Square") of the five simple regressions, these variables did not effectively have any bearing on the "achievement of objectives" variable ("R Square" smaller than 0.3).

Cultural Sensitivity	.288	.384	.087	.750	.457	-.481	1.057	.387	2.587
Dependent Variable: Achievement of Objectives									

Lastly, a final statistical analysis was performed. Analyzing the results of the multiple linear regression of the three variables selected as being influential in the achievement of objectives of the training programs—goal orientation, source of motivation, and metacognitive support—it can be seen that this model is very similar to the former multiple regression model (Table 4) which took eight variables into consideration. Table 7 portrays a summary of this model.

CONCLUSION, RESEARCH LIMITATIONS, AND FURTHER STUDIES

Concluding Remarks

Despite the fact that distance education has been around for over a century, the development of training programs has not achieved its full potential within organizations (Berge, 2002). Different technologies have been used since the creation of

the first distance training program, though Web technology is considered a watershed in this realm. While the technological progress has been impressive, the implementation of Web-based distance training has only increased at a slow pace (Cross, 2004). Besides the hype around Internet technology and its use in the business arena, the first trials using the Internet in corporate training arose at the end of the 20th century. However, most of these initial applications either failed or fell short of the expected outcomes (Cross, 2004).

For over a century, society has been trying to understand precisely how human beings learn. As with most problems in the social sciences, there is no single answer. However, it is clear that some rationale behind this research question must be developed. It must be remembered that Western society (mainly the USA) has been heavily influenced by the instructivist/behaviorist paradigm, upon which its educational system was designed (Criswell, 2000).

On the basis of theoretical references and case research analysis, it became clear that the deployment of Web-based training programs is not merely a technological issue. As in any training program, the inherent objectives and characteristics that it is seeking to achieve must be analyzed by the designers, so as to permit selection of the most adequate learning theory and define the instructional design, as well as develop and deploy the training program adequately.

Based on the comparison of averages, it was concluded with 5% level of statistical significance that there was no difference between the pedagogical philosophy and structural flexibility dimensions in the two cases analyzed. The sample averages of the former dimension (1.96 for Program A and 1.85 for Program B) indicate that both programs were highly instructivist, namely most of the knowledge is imparted by the training, rather than constructed by the students themselves. In other words, most of the learners' prior experiences were not taken into consideration in either case. This tallies with some authors who reveal the hurdles in developing a constructivist Web-based corporate training program in an environment where efficiency is pursued in order to be attained in a short time frame (see, for instance, Criswell, 2000; Joia, 2001; Joia & Casado, 2007). Likewise, the sample averages of the latter dimension (2.69 for Program A and 2.88 for Program B) pointed to the fact that "fixed" training programs are still dominant in corporate training, as in neither of the programs could the learners use the systems irrespective of time and/or location.

Thereafter, applying a linear multiple regression between the dimensions of the model developed by Reeves and Reeves (1997) and the achievement of objectives of both training programs, it can be seen that five out of the eight remaining dimensions of the theoretical model did not have a significant influence on the results of either program. Actually, the dimensions that effectively had a major impact on the outcomes of training Programs A and B were goal orientation, source of motivation and metacognitive support.

The low averages observed for the goal orientation dimension (2.94 for Program A and 1.58 for Program B) indicate that the objectives of both programs were more specific than generic. However, it is important to note that Program A aimed at achieving somewhat higher-order goals (namely leadership skills) than Program B. Conversely, Program B set out to address sharply focused goals (namely the firm's processes). In other words, with respect to this dimension, Program A was less instructivist/behaviorist than Program B.

This result duly corroborates the ideas of several authors who argue the need for a broader orientation for the success of a distance training program, that is, one that elicits more than the mere solution of specific problems (see, for instance, Dick & Carey, 1996; Kay et al., 1970; Mager, 1972; Sancho, 1998, to name just a few).

Program B—with an average of 1.06—had hardly any metacognitive support, whereas Program A—with an average of 3.00—revealed a certain level of implementation of this dimension. Once again, based on data collected from informal interviews, the users of Program B declared that there was no tool for students to track their progression during this training program. Moreover, regarding metacognitive support, the actual description of the features available in Program B to students, from the program managers' perspective, namely access via the intranet and multiple choice questionnaires, reveals and supports the lack of means for users to assess their learning strategies in a timely manner.

On the other hand, Program A did indeed provide some opportunities for students to develop the kind of assessment addressed above. The tool upon which this program was built allowed the users to track their outcomes at each stage of training, as well as the percentage of total time available to complete the course, and the estimated total time necessary to accomplish each stage of the program. Furthermore, Program A allowed the students to check back on content they had already studied on the course, thereby enabling them to control their learning process, as suggested, for instance, by Nevado et al. (2004), Campbell, Strijbos, Karel Kreijns, and Beers (2000), and Costa, Fagundes, and Nevado (1998).

Lastly, Program B users' assessment concerning the source of motivation dimension produced an average of 1.26, indicating that the source of motivation was mostly extrinsic. On the other hand, in Program A (average of 2.41), it becomes clear that there was at least some prior intrinsic source of motivation during the training program per se, probably due to the fact that these employees had just been promoted to managers. Thus, it can be considered that more than being motivated by the course, the students were supposed to be motivated by the company and their careers—a claim supported by interviews developed with five users of Program A. Conversely, the users of Program B did not appear to be motivated to take part in the training program, except for external motivation based on the mandatory nature of the program. Interestingly, this result complies with the ideas of Carroll (1968), Amabile (1993), and Keller and Suzuki (2004) about the importance of taking intrinsic motivation into account in any pedagogical model.

Hence, from the comparison of the two cases, the following items can be considered key success factors in these Web-based training programs:

- Clear definition of training content, target employees and objectives of the program, seeking more than merely the solution of specific problems;
- Development of a source of intrinsic, as opposed to extrinsic, motivation;
- Implementation of Web-based metacognitive support.

Figure 2 depicts the inter-relationship and influence of the critical success factors in the development of Web-based distance training programs in a concise way. As suggested in Figure 2, the three key success factors accrued from the analysis of the results of this research vis-à-vis the theoretical background enable the selection of the learning theory, the instructional design and the technologies to be used in this endeavor. It is also important to highlight that there is a feedback process in the model of Figure 2, namely the factors interact among themselves during the life cycle of the training program.

It is interesting to note that according to Ertmer and Newby (1993) and Conole, Dyke, Oliver, and Seale (2004), the selection of a specific learning theory is not a key success factor by itself. Moreover, the realization that this dimension did not directly influence the outcomes accrued from selected programs A and B (as both presented instructivist/behaviorist characteristics) complies with Reeves' (1997) frame, as it does not support the allegation that an instructivist/behaviorist program is necessarily better than a constructivist/cognitivist one and vice-versa.

However, this is a point that must be the subject of in-depth investigation in future research addressing training in virtual environments. Program A presented a more constructivist/cognitivist approach than Program B, as witnessed by the fact that the averages of the three relevant dimensions in the former program were higher than the corresponding dimensions in the latter program. This tallies with some authors who have argued that the constructivist/cognitivist approach is best suited for Web-based distance training (see, for instance, Costa et al., 1998).

Research Limitations

As with all research, this project has a few limitations now set forth. First of all, the number of respondents—32 users of Program A and 31 users of Program B—led to a sample size limitation, preventing the authors from running one multiple linear regression for each training program. According to Hair, Anderson, Tatham, and Black (1998, p. 166), there should be at least five observations for each independent variable. As there were eight remaining variables, a sample of at least 40 respondents for each training program was required. Accordingly, a linear multiple regression adding a dummy variable for Program A and Program B had to be run. The outcomes of this latter regression have shown the difference between the degree of accomplishment of objectives of either program (Hair et al., 1998, pp. 167–168). Moreover, as programs A and B are not exactly equal, some other factors associated with their corresponding content and modus operandi, just to name two aspects, can also have had an influence on their respective outcomes. For instance, in the second program, the fact that the IT team designed much of the content, a task that should more appropriately have been performed by domain knowledge specialists, may also have affected the outcome.

Besides, there may have been motivational differences between the participants of the two programs, as well as differences regarding the participants' IT literacy, since the degree of general familiarity with these technologies may be an important factor in determining success or otherwise. Furthermore, this article attempted to establish the value perceptions of the employees regarding the outcomes of the two Web-based training programs analyzed. There are some limitations in this approach, as some of the variables derived from the Reeves and Reeves (1999) model are not such simple variables as to be clearly understood by the respondents beyond all reasonable doubt, even after various meetings with the author. Indeed, a certain degree of subjectivity and bias from the employees may have occurred (Scandura & Williams, 2000).

Lastly, this is not a cross-cultural research project. Therefore the aspect of whether or not there is any influence accruing from the Brazilian setting in the outcomes of this research is not analyzed. The reason for this lies in the very fact that there are as yet very few works about Web-based corporate training in Brazil in existence. In order that one can develop cross-cultural studies, it is important to have information about what is supposed to be compared.

Further Studies

This article naturally does not claim to be the ultimate research in this knowledge field. The subject deserves a great deal more study and investigation. Research involving a larger number of companies and focusing on each specific dimension involved in the development of Web-based distance training programs might reveal other important issues related to this realm, in order to allow the organizations to better understand, improve and measure the outcomes of these endeavors.

Lastly, as has been said earlier, it is important to fully understand whether or not the Brazilian environment influenced the outcomes presented. Moreover, it is also important to verify whether there are differences between Web-based corporate training programs conducted in developing countries (such as Brazil) and developed countries. Thus, there is still much ground to be covered in this area.

Chapter 6.5
Multi-Tier Framework for Management of Web Services' Quality

ABSTRACT

Web services are a new breed of applications that endorse large support from main vendors from industry as well as academia. As the Web services paradigm becomes more mature, its management is crucial to its adoption and success. Existing approaches are often limited to the platforms under which management features are provided. In this chapter, we propose an approach to provide a unique central console for management of both functional and nonfunctional aspects of Web services. In fact, we aim at the development of a framework to provide management features to providers and clients by supporting management activities all along the lifecycle. The framework allows/forces providers to consider management activities while developing their Web services. It allows clients to select appropriate Web services using different criteria (e.g., name, quality, etc.). Clients also make use of the framework to check if the Web services they are actually using or planning to use are behaving correctly. We evaluate the Web services management features of our framework using a composite Web service.

INTRODUCTION

Web services standard is a recent paradigm of emerging Web components. It combines a set of technologies, protocols, and languages to allow automatic communication between Web applications through the Internet. A Web service is any application that exposes its functionalities through an interface description and makes it publicly available for use by other programs. Web services can be accessed using different protocols, different component models, and running on different operating systems. They usually use hypertext transfer protocol (HTTP) (W3C, 1999) as a fundamental communication protocol, which carries exchanged messages between Web services and their clients. Web services use extensible markup language (XML)-based (W3C, 2006) messaging as a fundamental means of data communication.

Research on Web services has focused more on interfacing issues, that is, simple object access protocol (SOAP) (W3C, 2004), Web services description language (WSDL) (WSDL, 2001), and universal description, discovery, and integration (UDDI) (OASIS, 2005). Until recently, considerable efforts have been conducted to address the issues of management of Web services in service-oriented architecture (SOA).

Web services management is among the hot issues that are not yet mature. Ongoing research from academia and industry are still emerging. Management of Web services is critical for their success because they are being actually used in a wide range of applications, ranging from entertainment, finance, and healthcare to real-time critical applications. Management issues in Web service can be divided into two dimensions: (1) management of functional aspects, namely fault management, and (2) management of nonfunctional aspects such as quality of service (QoS). Quality of a Web service, referred to as QoWS in this chapter, reflects the quality of a Web service, both in terms of correctness of functional behaviour and level of supported QoS. A Web service supporting QoWS is said to be QoWS-aware.

Nowadays, management of Web services is highly platform-dependent which implies the following limitations: (1) management features are usually available to Web services providers but often not to other partners (e.g., clients, third parties); (2) management solutions are usually restricted to only one management aspect, functional or nonfunctional; and (3) most of management solutions require considerable amount of computer and network resources to be deployed and used.

The first limitation restricts the utilization of management information to providers who are using it to assess the QoWS of their Web services. However, other entities involved in SOA industry might need to use this information as well. Clients can use this information during discovery and selection of Web services so they can figure out those with desirable QoWS. Moreover, many providers are likely to offer Web services providing similar functionalities but with quite different QoWS. In such a competitive market, attraction and loyalty of clients are primarily based on high standards of provided QoWS.

In SOA, a significant amount of work is taking place to allow both Web services providers and their clients to define and concisely use QoWS during publication, discovery, and invocation of Web services. For example, to select from a set of potential Web services, the one which is mostly available, and has a low response time and/or an acceptable utilization fee is preferable.

This chapter presents our approach for management of Web services. This approach provides a unique central environment for management of both functional and nonfunctional aspects of Web services. In fact, we aim at the development of a framework to provide management features to Web services providers and clients by supporting management activities all along the lifecycle of a Web service, from specification to invocation. The framework allows/forces providers to consider management activities while developing their Web services. In fact, the provider should concisely and precisely describe QoWS factors during design and implementation of the Web service. These factors will/shall be used latter by clients to select appropriate Web services during the discovery and selection operations. Clients also make use of the framework to check if the Web services they are actually using or planning to use are behaving correctly in terms of functional and nonfunctional facets.

The concepts presented all along this chapter will be illustrated in details through a case study. A Web service example will be used to show how different phases of the Web service development lifecycle must be conducted while promoting good practices for advanced management activities. At each phase, information and documents required by the management framework are produced and their impact on management is thoroughly discussed.

This book chapter is organized as follows. The next section provides background information required for nonexpert readers to follow the flow of ideas in following sections. The following section discusses related work in management of Web services and their limitations. A composite Web service used to illustrate our management framework is introduced. The subsequent section details, in a step-by-step tactic, how different management activities proposed by our framework can be conducted at each phase during the development of a Web service. We show then promising experimental results while using the framework to manage the Web service introduced hereafter. We close the chapter by presenting conclusions and insights for ongoing and future work.

BACKGROUND

Web services are a new variant of Web applications. It is a new paradigm which allows different applications to communicate automatically with each other over the Internet. They are self-contained, self-describing, modular applications that can be published, located, and invoked across the Internet (Wahli, 2002). The endeavor of this new paradigm is to allow applications to be delivered over the Internet and to run across all kinds of computers and platforms.

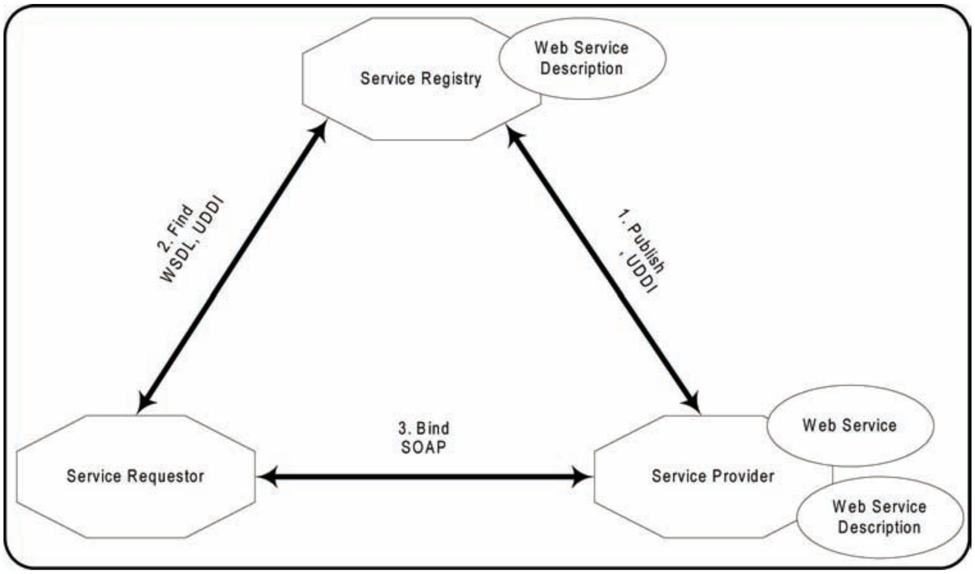
A Web service is any application that can be published, located, and invoked through the Internet. Each Web service has a Web service description language document (WSDL)(W3C, 2001), which consists of an XML (W3C, 2006) document providing all required knowledge to communicate with the Web service, including its location, supported transport protocols, messages formats, list, and signatures of published operations.

A Web service can perform any kind of transactions that may range from getting a city's temperature to a more complicated transaction, like for instance, searching and/or building the best travel packages from specific travel agencies. The main objective of Web services is to allow, at a high level of abstraction, applications to be accessible over the Internet. They can be of great use, for instance, for 3G networks operators to expose their core network functionalities to third parties (3GPP, 2003) and for digital imaging where they can provide an important benefit to the digital photography industry. The common picture exchange environment (CPXe) (CPXe, 2005), a Web service business framework, will make transfer and printing of digital images as suitable as the use of films.

SOA defines three roles (i.e., provider, requester, and registry) and three operations (i.e., publish, find, and bind). The relationship between the roles and the operations are illustrated in Figure 1. Additional information on the Web services architecture can be found by Kreger (2001).

The starting point in Web services activities is the development, deployment, and publication of the Web service by its provider. When a requestor (client) needs a specific Web service,

Figure 1. Service oriented architecture



the client probes the registry for a list of potential Web services. The returned list contains matching records; each record contains required information to connect to the corresponding Web service. Based on a set of criteria (i.e., location, availability, etc.), the requestor selects a suitable Web service and binds to it.

Web services can be developed either from scratch or by composition. Composition of Web services is the process of aggregating a set of Web services to create a more complete Web service with a wider range of functionalities. This composition has a considerable potential of reducing development time and effort for new applications by reusing already available Web services.

Currently, there are standards or languages that help in building composite Web services, such as: Web services flow language (WSFL) (Leymann, 2001), DAML-S (Ankolekar, Burstein, Hobbs, Lassila, Martin, McDermott et al., 2002), Web services conversation language (WSCL) (Banerji, Bartolini, Beringer, Chopella, Govindarajan, Karp et al., 2002), Web services choreography interface (WSC) (Arkin, Askary, Fordin, Jekeli, Kawaguchi, Orchard et al., 2002), and business process execution language (BPEL) (Andrews, Curbera, Dholakia, Goland, Klein, Leymann et al., 2003). These languages make the Web services composition process easier by providing concepts to represent partners and orchestrate their interactions. BPEL, which represents the merging of IBM's WSFL and Microsoft's XLANG, is gaining a lot of interest and is positioned to become the primer standard for Web service composition.

RELATED WORK

Most works on Web services focus on their development and deployment. Management of Web services (W3C, 2002), and in particular fault and performance management, are not yet a well-studied area. However, some interesting works have to be cited.

Existing approaches for management of Web services include approaches from network management and those that have been developed specifically for Web services. The approaches that have been used for network management for a long time seem to be a candidate for the management of Web services. However, their main drawbacks are due to the major differences between Web services and network components, and the need for the participation of a component in its management. In fact, most network components (devices) run standardized protocols that have specific and known attributes to be managed. Manufacturers of components running proprietary/no-standard protocols and/or applications often provide their customers with specific management agents/applications or well-defined sets of APIs.

In network oriented approaches, simple network management protocol (SNMP) (Case, Fedor, Schoffstall, & Davin, 1990) is based on TCP/IP and the client/server communication mode. In this approach, an agent associated with a management information base (MIB) (Perkins & McGinnis, 1997), communicates with a management station by processing ***get*** (report the value of an attribute) and ***set*** (modify the value of an attribute) messages and generating ***trap*** messages (unsolicited notification). Thus, SNMP management system requires a SNMP agent, a MIB, and a management station (manager).

The common management information protocol (CMIP) (ISO/IEC, 1998) fulfills in the OSI reference model protocol stack (ISO/IEC, 1989), a role similar to that of SNMP in TCP/IP. CMIP has many advantages compared to SNMP, including the number of available commands and the possibility to operate over TCP/IP. However, complexity and long development time, especially CMIP over TCP/IP (CMOT) (Warrier, Besaw, LaBarre, & Handspicker, 1990), have kept its adoption pervasively.

A considerable amount of work in the Web services community is dedicated to the determination of the requirements and the definition of specific approaches for Web services management. These approaches can be divided into two main groups: approaches based on active testing and approaches requiring the Web service (architecture) to support management interfaces. The World Wide Web (W3) Consortium presents a set of requirements that Web services management architectures should satisfy to provide management features (W3, 2004). This includes the definition of standard metrics, management operations, and methodologies for accessing management capabilities. The complying architectures must provide a manageable, accountable, and organized environment for Web services operations. It must support at least resource accounting, usage auditing and tracking, performance monitoring, availability, configuration, control, security auditing and administration, and service level agreements. Another approach in which the Web service provides specific interfaces for management is presented by Farrell and Kreger (2002). The developer is supposed to supply commands and APIs for management operations that are invoked by the management system.

Casati, Shan, Dayal, and Shan (2003) classify the management of Web services into three levels: infrastructure-level, application-level, and business-level. The infrastructure-level deals with the Web service platform while the application-level focuses on the Web services themselves. The business-level takes into consideration the conversations between a Web service and its client

Management approaches presented by W3 (2004), Farrell and Kreger (2002), and Casati et al. (2003) assume that the Web service will provide management operations that one can invoke. Developers of Web services have then to develop and deploy these operations in addition to the core business operations the Web service is offering.

A couple of management tools to be integrated into Web services environment are already available. Hewlett Packard's Web service management engine (HP, 2007) is a collection of software components that enables some management features, including the definition and the enforcement of service level agreement (SLA). Parasoft (2006) provides a set of tools (e.g., SOAPTest, .TEST, WebKing) to assist during the lifecycle of a Web service. These tools have to be installed and configured, thus requiring extra resources and introducing new cost for Web services providers.

There has been a considerable amount of work on testing Web services in the last couple of years. The work can be divided into two main groups: works targeting functional aspects of Web services and works tackling nonfunctional. The first group is concerned with the correctness of interactions between Web services and their clients while the second group is concerned with QoS management of Web services.

Functional Management

The majority of work on functional management is based on active testing where appropriate test cases have to be carefully generated, executed, and their results analyzed. This unavoidable phase of active testing has, however, practical limitations. First of all, exhaustive testing is impractical for quite large Web services. In fact, test cases can not cover all possible execution scenarios that a Web service will have to handle while serving clients' requests. The size of test cases is bounded by the cost a Web service's provider is willing to spend on testing activities. Usually, active testing stops whenever developers are confident that the Web service is good enough to be put into the market.

Many recent results were published lately describing test cases generation methods for Web services; they are mainly based on static analysis of WSDL documents. Xiaoying, Wenli, Wei-Tek, and Yinong (2005) present a method for test data generation and test operation generation based on three types of dependencies: input, output, and input/output. Jiang, Xin, Shan, Zhang, Xie, and Yang (2005) propose a method for test data generation in which a set of tests is randomly generated based on the WSDL document. ChangSup, Sungwon, In-Young, Jongmoon, and Young-Il (2006) combined both EFSM models and WSDL documents to generate test cases.

QoS Management

QoWS management includes definition of QoS attributes, QoS publication, discovery, validation, and monitoring. Existing approaches for QoS management can be classified into two groups: one based on extending related technologies including WSDL and UDDI to support QoS and the other mandating independent entities to perform some or all of QoS management tasks.

In the first category, W3C (2003) extends SOAP header to include QoS information. WSDL is also extended to describe QoS parameters, their associated values, computation units (e.g., millisecond, request/second), and so forth. UDDIe, a UDDI extension, consists of extending the current UDDI data structure with QoS information (ShaikhAli, Rana, Al-Ali, & Walker, 2003). The aim of these extensions is to allow QoS-based publication and discovery of Web services.

In the second group, solutions are presented for one or more of the following QoS management operations:

- **QoS attributes:** The first step in QoS management is the definition of evaluation's criteria and attributes. A set of attributes have been defined, studied, and used in software engineering for a long time (Fenton & Pfleeger, 1997; Gray & MacDonell, 1997; Salamon & Wallace, 1994).
- **QoS publication and discovery** (Kalepu, Krishnaswamy, & Loke, 2004; Ran, 2003; Serhani, Dssouli, Hafid, & Sahraoui, 2005): This operation allows providers to include QoS information in WSDL. This information is then used by requestors when selecting the appropriate Web service in terms of functional and QoS requirements.
- **QoS verification** (Kalepu et al., 2004; Serhani et al., 2005; Tsai, Paul, Cao, Yu, & Saimi, 2003): This operation allows the provider to certify that the QoS claimed by the Web Service is accurate.

- **QoS negotiation** (Serhani et al., 2005): If the available published QoS requirements do not satisfy a client's needs, negotiation operations and strategies can be followed to reach an agreement on different QoS attributes.
- **QoS monitoring** (Benharref, Glitho, & Dssouli, 2005; Benharref, Dssouli, Glitho, & Serhani, 2006; Ho, Loucks, & Singh, 1998; Schmietendorf, Dumke, & Reitz, 2004; Yuming, Chen-Khong, & Chi-Chung, 2000): Performs monitoring of Web services during interactions with clients to assess if the QoS attributes agreed upon in previous points are delivered.

Discussion

All the solutions presented above fit in one or more of the following categories:

1. Platform-dependent
2. Assume that a Web service will participate in its management by providing specific interfaces (e.g., W3C architecture)
3. Are based on active testers

The usage of platform-dependent management approaches is restricted to the targeted platform. When management features are embedded to the hosting platform, they are only available to the provider and cannot be used by clients or third party certification entities. A client might need management information for two tasks: (1) during discovery and selection to select the appropriate Web service, and (2) during invocation to assess the quality of the interactions. The client must rely on management information made available by the Web service provider and has no mean of verifying it. Moreover, information used in assessing the behavior is taken from one location, that is, at the provider's side. There are many situations, in composite Web service for example, where this information should be gathered from different sources and locations.

The Web services architecture becomes more complex if it has to support management features in addition to its basic functions. The performance of the Web service and its hosting platform is also degraded due to these additional features. Moreover, developers of Web services have to also implement the needed interfaces and APIs to support management. Since these features will be used somehow sporadically, the return on investment of their development and deployment might be relatively low.

Once a Web service is interacting with clients, active testing cannot be used to monitor, in real time, the correctness of interactions. Moreover, application of generated test cases consumes resources and may disturb the Web service.

Since management of Web services is somehow at its earlier stages, related work usually concentrates more on provision of management features without evaluating the overhead they generate. In order to select the appropriate management approach, a potential user must be able to evaluate it in terms of usefulness and associated cost.

Furthermore, most of the existing work on management of Web services does not tackle management issues at the earlier phase of their development. However, management features need to be addressed as early as possible in the development process, especially during the design and implementation phases. For example, design for manageability will describe manageability scope and functions. Moreover, it will expose a Web service as a manageable entity providing some of the following capabilities (Farrell & Kreger, 2002): operations, events, interfaces, status, configuration, and metrics that can be used for managing and controlling Web services.

To solve some of the limitations of related work cited above, this chapter presents a novel framework for management of Web services. This framework considers QoWS management issues from earlier phases of the development lifecycle of a Web service. These issues are specified during specification and design, verified and certified before deployment, published with the WSDL document, used during discovery and selection, and passively monitored during invocation of the Web service.

To illustrate the applicability of our approach for management of Web services, we will be using a case study all along the chapter's sections to demonstrate how each management task, at each development phase, can be achieved. Introduction to this case study and its utilization context are given in the next section.

CASE STUDY

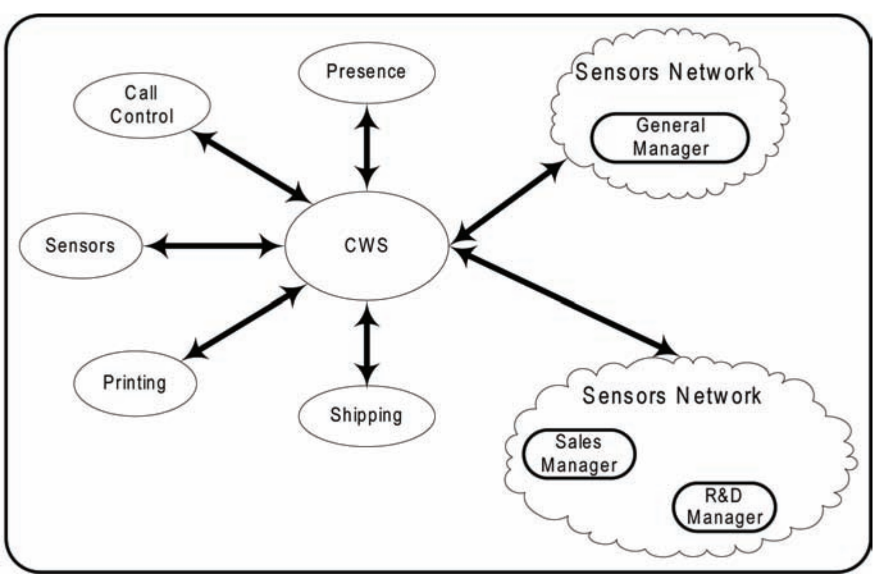
For the end of year meetings, a general manager has to meet with managers from different departments (e.g., Sales, R&D, etc.). Managers are located in different locations and, because of their busy timetables, they cannot meet in a single location. A practical alternative is to conduct these meetings in a series of teleconferences. Only mangers are concerned and only those of them who are in their offices can join a conference. This is implied by security issues since confidential information will be exchanged during meetings and communication between different locations is secured (e.g., VPN). At the end of each meeting, meetings' reports must be printed and distributed among all participants.

The manager decides to use available conferencing Web services. Such Web services should allow creation of conferences, and the addition and removal of participants to conferences depending on their profiles and physical locations. At the end of each meeting, the Web service should be able to submit produced reports for printing and deliveries.

The general manager is highly concerned with the environment in which meetings will be carried out using Web services. A thorough QoWS-based discovery and selection operation had lead to the utilization of "conferencing Web service" (CWS), a QoWS-aware composite Web service, which performs all of the required tasks. The manager decides to make use of the monitoring feature of the management framework to assess the QoWS of the CWS.

To perform all these tasks, the CWS is a composition of the following basic Web services (Figure 2):

Figure 2. Composite/basic Web services



- **Presence:** This Web service contains information on managers' profiles (e.g., name, address, location, status, position, and availability).
- **Sensors:** This Web service detects the physical location of managers.
- **Call Control:** This Web service creates and manages multiparty conferences (e.g., initiates conferences, adds/removes participants, and ends conferences).
- **Printing:** At some points during conferences or later on, managers may want to print documents (e.g., meeting reports, etc.). The printing Web service will print these documents and keeps them for shipping.
- **Shipping:** Documents printed during and after the conference should be distributed among participants at different locations. The CWS informs the shipping Web service of the location of the documents to be shipped and their final destinations.

WEB SERVICES MANAGEMENT FRAMEWORK

For a better exploitation of Web services, a Web services lifecycle is supposed to integrate features such as QoWS factors' precise definition, QoWS specification, QoWS-based discovery and selection, and QoWS monitoring. This implies that these features need to be addressed in earlier phases through Web services development process, especially during the design phase, then ultimately in the implementation phase, and possibly during selection and invocation of the Web service. QoWS management information, for example, is first specified then published to be later on discovered by clients using QoWS-aware discovery. Our approach is to investigate possibilities to augment the development process of Web services with the above important features.

In the subsequent sections, we will describe how management of QoWS should be supported during development, publication and deployment, discovery, selection, and invocation.

During Development of the Web Service: Behavior's Specification

The first step in a QoWS-aware development and utilization of Web services is the selection and concise definition of factors that will characterize the quality of a Web service. As cited above, these factors are divided into functional and nonfunctional aspects.

Functional Aspects

Definition of functional attributes specifies the correct functional behavior of the Web service for each invocation of each published operation. This covers the content of invocations, their responses, and their sequence.

Two main ways for functional behavior's description have been studied in the literature, concentrating on formal models and knowledge bases/expert systems (Vijayananda & Raja, 1994). Formal models have many advantages over expert systems. First of all, expert systems rely on human expertise and are more appropriate for systems that have been encountered previously. Second, formal models can be useful for automatic generation of source code and executable test cases. For these reasons, finite state machines (FSM) (Dssouli, Saleh, Aboulhamid, En-Nouaary, & Bourhfir, 1999), a widely known formal model, will be used to specify expected functional behaviors of Web services in this chapter.

A finite state machine M is defined as a tuple $(S, S_0, X, Y, D_S, \delta, \lambda)$, where

- S is a set of states,
- $S0 \in S$ is the initial state,

Figure 3. XML representation of an FSM machine

```
<fsm name="Conferencing Web Service ">
 <state name="Init" initial="YES">
          <transition ID="t1"          input="Config_Valid" output="True" next="Ready"/>
          <transition ID="t2"          input="Config_Invalid" output="False" next="Init"/>
 </state>
 <state name="Ready" initial="NO">
<transition ID="t3"          input="CreateConf_Valid" output="True" next="ConfCreated"/>
 </state>
 <state name="ConfCreated" initial="NO">
          <transition ID="t4"          input="AddUser"output="True" next="ConfCreated"/>
 </state>
…
</fsm>
```

- X is a finite set of inputs,
- Y is a finite set of outputs,
- $D \subseteq S \times X$ is the specification domain,
- $\delta: D^S \rightarrow S$ is the transfer function, and
- $\lambda: D^S \rightarrow Y$ is the output function.

The machine starts at S_0. Whenever an input is received, λ computes the corresponding output and δ determines the corresponding next state(s).

An FSM can be represented by an XML document as illustrated in Figure 3, which gives a partial overview of the FSM machine of the CWS. The root of the document (***fsm***) has an attribute (***name***) and a set of children which represents states. The name is a textual description of the Web service. Each child has a name, the attribute (***initial***), and a set of ***transitions***. The name is a textual description of the state while the attribute "initial," if set to YES, indicates that this is the initial state of the machine. A transition has four attributes: ***ID***, ***input***, ***output***, and ***next***. The first attribute is a textual description of the transition, the second attribute identifies the event that triggers this transition if the machine is in the associated state, the third attribute is the output generated when firing that transition, and the last attribute specifies the state that the machine will reach after firing the transition.

Nonfunctional Aspects: QoS

QoS consists of a set of factors or attributes such as response time, reliability, availability, accessibility, and so forth. Information on QoS attributes can be specified in many different ways. It can be described in a separate document, embedded within the description of functional behavior, or as an extension to WSDL document. However, to allow QoWS-aware discovery and selection of Web services, QoWS attributes should be available within the WSDL document. The client indicates preferences in terms of QoWS when probing the registry. The registry returns then a list of available Web services providing required operations with requested QoWS.

The first step in extending SOA with QoS is the definition of QoS attributes. In this chapter, we will focus on the following attributes:

- **Processing Time (PT):** This is a measure of the time a Web service takes between the time it gets a request and the moment it sends back the corresponding response. PT is computed at the Web service's provider side.

- **Maximum Processing Time (MxPT):** This is the maximum time the Web service should take to respond to a request.
- **Minimum Processing Time (MnPT):** This is the minimum time the Web service should take before responding to a request. Unlike PT, which is a dynamically computed attribute, MnPT and MxPT are statically defined and MnPT ≤ PT ≤ MxPT.
- **Response Time (RT):** It consists of the time needed between issuing a request and getting its response. It is measured at the client's side to include the propagation time of requests and responses.
- **Maximum Response Time (MxRT):** This is the maximum accepted time, for the client, between issuing a request and getting its response.
- **Minimum Response Time (MnRT):** This is the minimum time, for the client, between issuing a request and getting its response. This attribute in unlikely to be used since the client is usually more interested in MxRT. For the client, RT ≤ MxRT must always be satisfied.
- **Availability:** This is a probability measure that indicates how much the Web service is available for use by clients. It can also consist of the percentage of time that the Web service is operating.
- **Service Charge (SC):** It defines the cost a client will be charged for the Web services utilization. SC can be estimated by operation, type of requests, period of utilization, session, or by volume of processed data.
- **Reputation:** This is a measure of Web services' credibility. It depends basically on previous end users' experiences while using the Web service. Different users may have different opinions on the same Web service. The reputation value can be given by the average ranking given to the Web service by several users.

MnPT, MxPT, availability, and SC are related to profiles of users of the Web service. This profiling is based on the type of subscriptions of clients and/or the QoWS they are willing to pay for. For

Figure 4. QoWS in WSDL document

```
<?xml version="1.0" encoding="UTF-8"?>
 <wsdl:portType name="ConferenceService">
  <wsdl:operation name="addUser" parameterOrder="userAddresse callID">
   <wsdl:input message="intf:addUserRequest" name="addUserRequest"/>
   <wsdl:output message="intf:addUserResponse" name="addUserResponse"/>
            <Profile name="GOLD">
                  MnPT = NULL
                  MxPT = 10ms
                  SC= "$10"
            </Profile>
            <Profile name="SILVER">
                  MnPT = 10ms
                  MxPT = 30ms
                  SC= "$5"
            </Profile>
  </wsdl:operation>
 </wsdl:portType>
```

example, a gold-subscribed user must be served quicker (MnRT = 0) than a bronze-subscribed user (MnRT > 1ms).

Figure 4 illustrates embedded QoS attributes in the definition of the operation tag within the WSDL document of the CWS.

Before Deployment and Publication: QoWS Verification and Certification

Once a Web service is developed, it must be tested to verify whether it is correct with regards to the behavior's specification document produced during preceding development phases. The management framework has features that a Web service's developer can use to verify and certify the Web service's behavior. This certification information is then published with the WSDL description of the Web service so potential clients will use it.

Verification and certification procedures enable providers to evaluate QoWS of their Web services prior to the publication. Our approach consists of a two-phase verification and certification technique, which is conducted by a verifier Web service and a certifier Web service (Figure 7). The first phase consists of verifying the WSDL document, including the QoWS parameters description. The second phase consists of applying a measurement technique to compute the QoWS metrics stated in the Web service interface and compares their values to those claimed in the WSDL document. This is used to verify the conformity of a Web service to its description from a QoWS point-of-view (QoWS testing). Therefore, a set of QoWS test cases are defined and used as input to QoWS verification. The configuration and generation of these test cases is described in detail by Serhani et al. (2005). Once the Web service passes the verification tests, the certifier issues a conformance certificate to certify that QoWS claims are valid. This certificate will be considered as a key differentiator between Web services offering similar functionalities. The verifier and certifier perform the following tasks:

- It asks for information about the provider and its Web service (e.g., servers' resources capacity, connections used, Network information, etc.).
- It checks the WSDL files of the target Web services (e.g., location, interface, and implementation description)
- It makes sure that all published operations are available.
- It verifies the QoWS described in WSDL. The QoWS verifier can initiate, if necessary, additional tests to validate other information provided in the WSDL document. This information concerns QoWS attributes classification (e.g., definition, computation logic, and upper and lower bounds).
- It stores the verification report in a specific-purpose database.

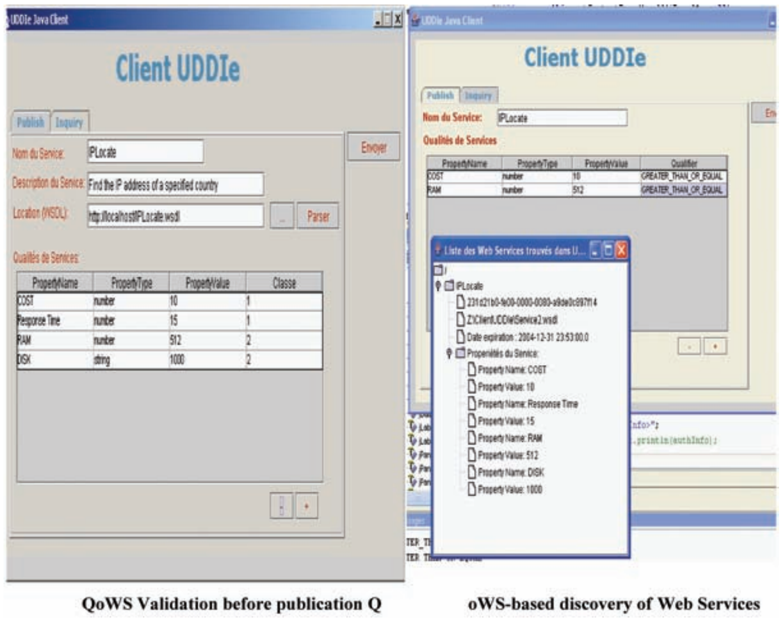
During Discovery and Selection: QoWS-based Discovery and Selection

In standard SOA, the find operation is based on the name of the Web service. A client is likely to get a list of Web services following a basic find operation issued to a UDDI registry. Alternatively, an intelligent find operation must consider, in addition to the name, QoWS information verified and certified in the previous phase, so the returned list of Web services is somehow short and concise.

Our framework defines how an intelligent discovery operation should look like and how it can be used. Discovering a Web service will be based on its functionalities as well as its QoWS. We automated the processes of publication and discovery of Web services based on QoWS using a supporting application (Figure 5), which allows the following tasks:

- **Publication:** In order to publish their Web services using our application, providers

Figure 5. UDDIe client's application for QoWS-driver publication and discovery



should supply the Web service name, description, and the location of its WSDL document. This document is then parsed to validate its content and to display the list of QoWS information. The validation process verifies the correctness of published operations in addition to the QoWS information. The provider can add/remove/modify QoWS attributes before publication. At this stage, the WSDL document is validated and the provider publishes the QoWS-enabled WSDL document.

- **Discovery:** The application allows the user to query the registry while specifying the Web service name and the set of required QoWS attributes and their related values. The list of Web services descriptions that fulfill the client's requirements is displayed via the application interface. The frame contains corresponding Web services and their associated QoWS information.

During Invocation: QoWS Monitoring

During interactions between a Web service and its client, it might be necessary to assess if the Web service is behaving as initially specified and claimed in previous subsections. This assessment will require a continuous online monitoring of interactions between the Web service and its client.

Online monitoring of Web services requires passive observers (Benharref et al., 2005, 2006). A passive observer receives a copy of all exchanged messages between a Web service and its client and checks their validity. Passive observation of systems modeled as FSM is usually performed in two steps (Lee, Netravali, Sabnani, Sugla, & John, 1997):

1. **Passive Homing (or state recognition):** In this step, the observer is brought to a state equivalent to the one that the Web service might be in. If no such state is found, a fault

is immediately reported. The set of messages leading to this state is known as the homing sequence. This first step is required if observation starts while the Web service and its client already exchanged some messages. These messages will not be available to the observer but the latter can figure out a homing sequence to determine the appropriate state.

2. **Fault Detection:** Starting from the state identified in the previous step, the observer checks the observed behavior against the system's specification. If an observed event is not expected then a fault is immediately reported.

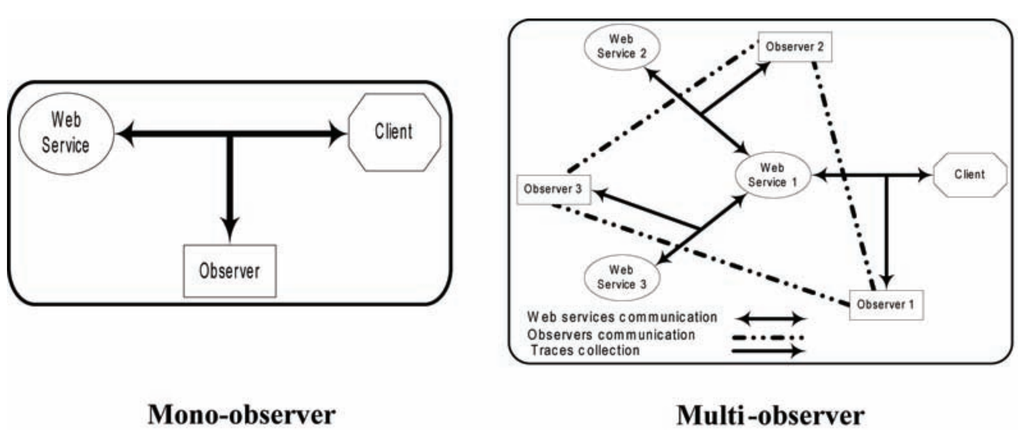
The observation in distributed architectures requires the selection of a number of observers and their best locations (where to get copies of exchanged messages). The number and location of the points of observation affect significantly the detection capabilities of the observation architectures. For example, if the observed Web service is a composite Web service, it might be more interesting (in terms of misbehavior detection) to consider a network of observers, that is, an observer for each Web service rather than a unique observer for the composite Web service. In such architectures, cooperation of all observers can generate pertinent information for Web services management. The consideration of a global observer (for the composite Web service) and local observers (for composing Web services) presents a framework where this cooperation can be orchestrated for the benefit of better misbehavior detection.

Our Web services management framework offers two monitoring architectures as depicted in Figure 6, which shows a mono-observer architecture (Benharref et al., 2005) and multiobserver architecture (Benharref et al., 2006).

Three types of interactions are illustrated in Figure 6. Web services communication refers to the SOAP-based communication between Web services and their clients. Traces collection consists of forwarding messages exchanged between the observed Web service and its client to local observers. Observers communication conveys information between observers. This information is divided into three categories:

3. **Configuration information:** During configuration of different observers, local observers must indicate to the global observer which Web service they are observing and where they are located. The global observer needs this information to identify observers and associates the traces it will receive to

Figure 6. Monitoring architectures



appropriate observers/Web services.

4. **Traces from local observers to the global observer:** Whenever a local observer gets a trace, it sends it to the global observer.
5. **Notifications of faults:** If the global observer detects a fault, it informs other local observers. In the case where a local observer detects a fault, it informs the global observer. The latter informs remaining local observers that misbehavior has been observed elsewhere and they should be aware of some specific traffic/actions.

Traces collection mechanisms studied by Benharref et al. (2005) show that mobile agents present the least overhead. Whenever an entity wants to use monitoring architectures, it invokes a Web service observer (WSO) that generates a set of mobile observers and sends them to locations specified during invocation.

Except specification of expected behaviors of Web services which has to be done by the provider, other management operations presented in previous sections are performed by invoking the verifier, the certifier, and the observer, three Web services provided by the management framework. These components and their associated operations are illustrated in Figure 7.

Different steps discussed above have been applied to a set of Web services to illustrate their applicability. The next section shows an example of application to the CWS introduced earlier in this chapter.

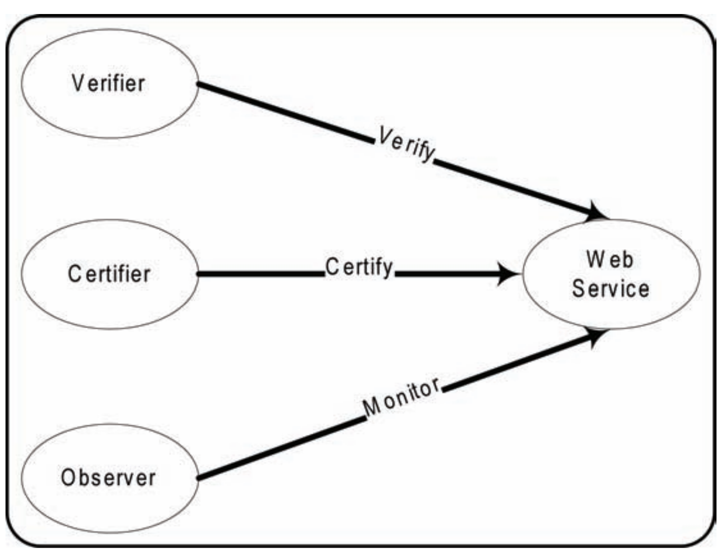
EXPERIMENTATION AND RESULTS

As indicated earlier, CWS is a composite Web service for management of teleconferences, printing, and shipping of teleconferences reports. Experimenting with the framework using this Web service required implementation and deployment of a dozen of Web services.

Implementation Issues

All Web services, including the WSO, are implemented in BEA WebLogic (BEA, 2004). Mobile observers get traces using SOAP handlers, which are available within the BEA platform. A SOAP handler, a specific-purpose Java class, intercepts a request/response to/from a Web service before it

Figure 7. Management framework components and operations



gets to the core Web service or the client respectively, and can also perform operations on it. In our case, the SOAP handler sends each intercepted request or response in a user datagram protocol (UDP) datagram to the concerned mobile observer all along with the date at which this event occurred to allow the observer to assess QoS attributes such as response time. The mobile observer checks this trace and forwards it to the global observer.

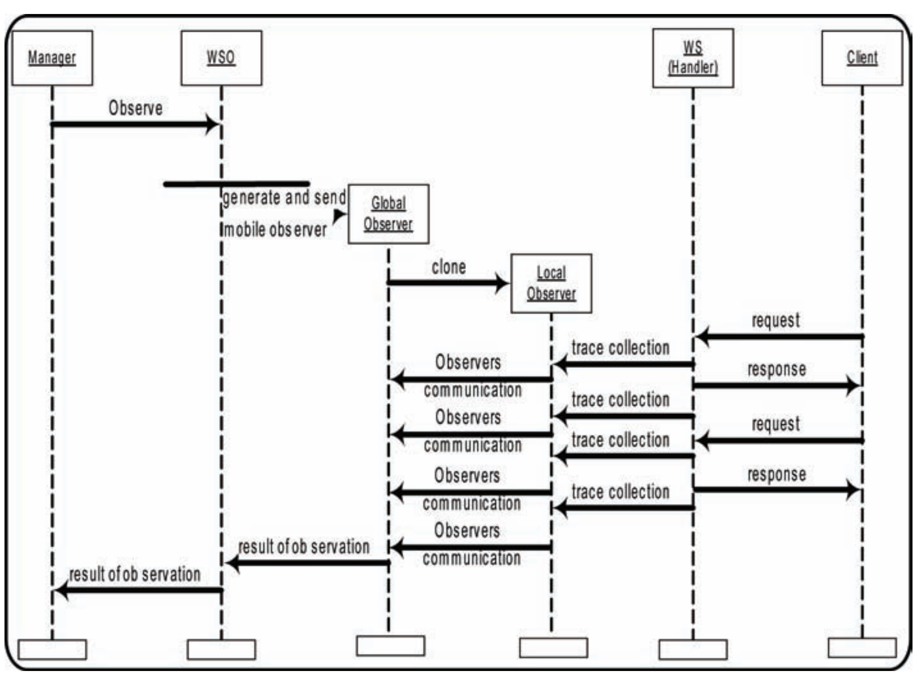
To be able to detect lost UDP datagrams, a sequence number field is used. When a mobile observer detects a lost datagram (wrong/not expected sequence number), it suspends the misbehavior detection and reperforms the homing procedure. It restarts the detection once this procedure is achieved correctly. Since the behavior/operation of SOAP handlers within all observed Web services is similar, a unique (generic) SOAP handler is developed and then distributed to all providers participating in the observation.

The overhead of the management framework can be quantitatively evaluated with regards to required computer resources and generated network overhead. Both analytical analysis and experimentations showed that most of the overhead is related to the online monitoring. In fact, the verification and certification operations are straightforward and usually conducted off-line, that is, before the Web service is made available to clients. Moreover, all required resources are located at the verifier and certifier Web services providers. For these reasons, overhead analysis presented in upcoming subsections will concentrate on online monitoring, especially traces collection.

Monitoring

In addition to the observation of the CWS, the manager wants to make sure that all the steps are performed according to the agreed on contract and QoWS. Fortunately, all the providers accept to participate, to some extent, in the monitoring. The provider of the CWS will host all mobile observers using the Jade platform (Jade, 2007). This provider will also supply WSDL documents and

Figure 8. Multiobserver deployment



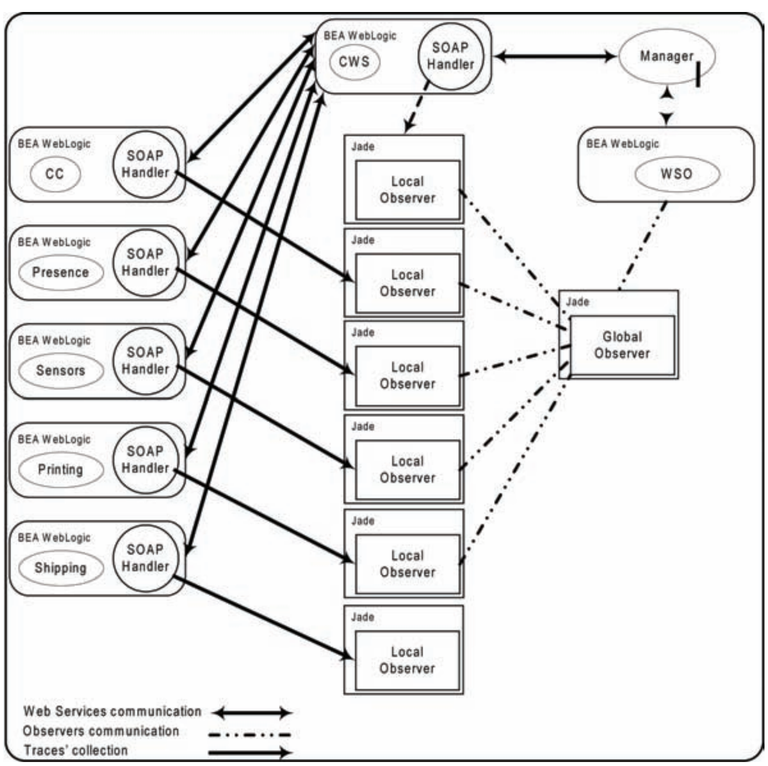
FSM models of each of the basic Web services. Basic Web services providers will configure SOAP handlers for traces collection and forward.

The observation procedure of CWS is performed following the steps detailed below and illustrated in Figure 8. To keep the figure simple, just one Web service handler and one Web service client[1] are depicted in the figure.

1. The manager invokes the WSO, providing different locations of mobile observers.
2. The WSO generates a mobile agent and sends it to one of the destinations submitted during invocation in Step 1.
3. Once the mobile agent gets into its destination, it clones itself as many times as required to observe all Web services.
4. The mobile agent observing the CWS becomes the global observer; other mobile observers are local.
5. SOAP handlers forward traces to appropriate mobile observers.
6. Local observers analyze these traces and forward them to the global observer.
7. Whenever misbehavior is detected (by global or local observers), correlation then fault location is initiated by the global observer to find the faulty Web service.
8. The global observer reports to the WSO.
9. The WSO reports to the manager.

Each local observer is listening to a UDP port to receive events from SOAP handlers. The global observer is listening to two different UDP ports: one to receive events (request or response) from local observers and another port to receive information on detected misbehaviors by local observers. The SOAP handler sends each event between a client and its Web service to the attached local observer. The latter forwards this event to

Figure 9. Multiobserver configuration for monitoring of CWS



the global observer and checks the validity of this event. If misbehavior is detected, the local observer notifies the global observer. Figure 9 shows the overall configuration of interacting client, Web services, mobile observers, and communication between these entities.

Processing CPU and Memory Utilization

Computer resources (CPU and memory) used by traces collection entities are somehow insignificant with regards to the minimal standard configuration of actual personal desktops/laptops. Except for the mobile agent approach, CPU and memory utilization are so low that they are even difficult to precisely evaluate.

For mobile observers, CPU and memory utilization on a laptop equipped with an AMD Athlon 64/3000+ processor and 512MB RAM, CPU and memory utilization are as follows:

- **Hosting a mobile platform:** If the mobile agent administration interface is located on the laptop, the CPU utilization varies between 2% and 4%. For memory, it uses around 30 Megabytes.
- **Joining a mobile platform[2]:** If the mobile agent platform is running on a remote computer, joining it requires 12 MBytes memory at the laptop and around 2 MBytes on the host running the administration interface. For CPU, there is almost no impact at both sides.
- **Receiving a mobile observer:** When a mobile observer is received, it requires around 27 MBytes of memory. For CPU, there is a high utilization during 1 to 2 seconds while initializing and displaying the graphical interface of the mobile observer, then the CPU utilization goes back to previous level
- **Processing traces:** Even in the worst case where traces are received with a very small delay, the CPU used by the mobile observer for analyzing them is around 2%. However, there is no additional memory utilization.

Network Load

The network load introduced by the observation is classified into load due to the deployment of mobile agents and load due to the traces collection process.

Deployment Load

Since all observers are located at the composite Web service provider's side, only one mobile agent is generated by the WSO. The size of the traffic to move a mobile agent is around 600 Kilobytes (600 KB).

Traces Collection Load

Generally, for each interaction between a Web service and its client, 2 UDP datagrams are generated: a first datagram from the SOAP handler to the local observer, and a second datagram from this local observer to the global observer. Whenever a local observer detects misbehavior, a third datagram is sent (fault notification). The average size of a datagram is 150 bytes. So, each response/request pair introduces 4 datagrams if everything goes fine, 5 datagrams if one of the events is faulty, or 6 datagrams if both are faulty. We suppose that faults will not occur very often, and then few fault notifications will be generated. This assumption is realistic since all Web services are supposed to undergo acceptable testing process before their deployment. The traces collection load then is reduced to the forward of events, that is, 4 datagrams for a request/response pair. This represents a load of 600 bytes.

Table 1. Some of the executed scenarios

Target Web Service	Fault description	Comments
CWS	Submit a printDocument request before creating a conference	Fault detected by local and global observer
Call Control	Add a user before creating a conference	Fault detected by local and global observer
Presence	Try to add a user to the conference that is not recognized by the Presence service	Fault detected by local and global observer
Shipping	Request shipping of a document that has not been submitted for printing	Fault detected by local and global observer
Shipping	A trace collection event (shipDocument response) from a handler to the local observer is lost (Figure 10)	Neither the local observer nor the global observer will detect the fault.
Shipping	A trace collection event (shipDocument response) or a fault notification from a local observer to the global observer is lost (Figure 11)	The global observer will not be able to detect the fault or process the notification (correlation)

Results and Analysis

To illustrate the detection capabilities of our architecture, we injected faults to some Web services and/or in the network and monitored the behavior of observers (Table 1). The observers have been able to detect most of the injected faults.

A fault that cannot be detected occurs when the last event in a communication between a Web service and its client is lost (see Figures 10 and 11). As discussed earlier, traces are sent as UDP packets. To be able to detect lost packets and recover the observation, a sequence number attribute is used. An observer detects a lost packet if the sequence number of the following packet is different than expected. When a lost packet carries the last event in a communication, observers will not be able to detect this incident since no future packets will arrive. Table 1 shows brief descriptions of some of the executed scenarios and the reactions of observers (both local and global) to the fault.

CONCLUSION

Web services are a new generation of Web applications. This new paradigm of communication puts more emphasize on business-to-business

Figure 10. Trace lost before getting to local observer

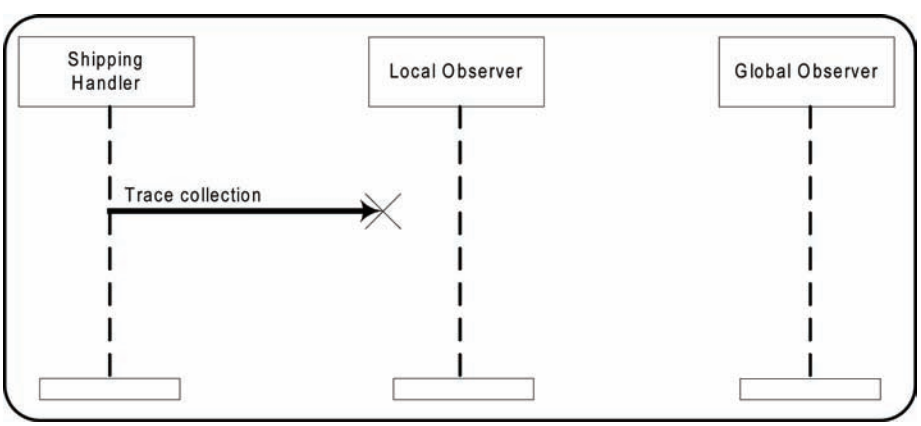


Figure 11. Trace or fault notification lost before getting to global observer

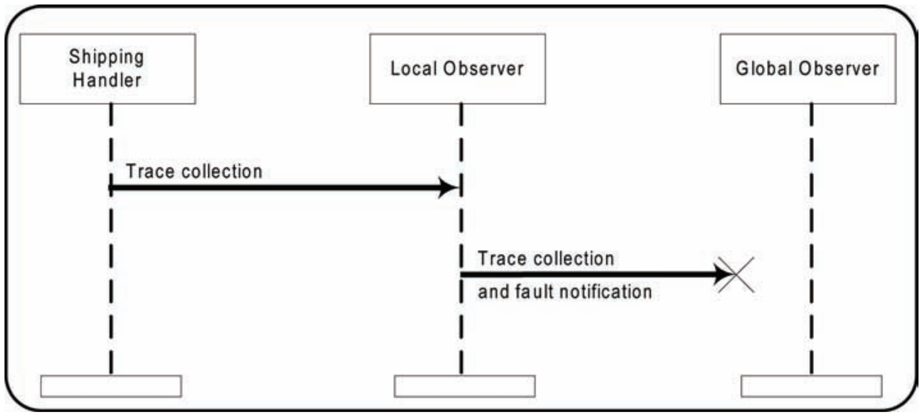

interactions rather than the business-to-consumer transactions model that the Internet was largely providing. Management of Web services is of prime importance for all entities involved in service oriented architecture. In an environment where the interacting components are not known a priori, can be on different operating systems and platforms, and coded in different programming languages, the management of Web services is very challenging compared to the management of traditional distributed systems.

In this chapter, we have developed a framework to provide management features to Web services providers and clients by supporting management activities all along the lifecycle of a Web service, from development to invocation. The framework encourages providers to consider management activities while developing their Web services by specifying QoWS attributes. It allows clients to select appropriate Web services using QoWS information published previously by providers. Clients also make use of the framework to check if the Web services they are actually using or planning to use are behaving correctly in terms of functional and nonfunctional facets. A prototype of the framework has been developed and used in management of a set of Web services. In this chapter, a conferencing Web service has been used to evaluate the effectiveness and the overhead of the framework.

As a future work, we intend to enhance the framework by providing support to other management operations, such as fault isolation and repair. Work is in progress to implement the remaining components of the framework and to evaluate the overall features of the framework on a large scale Web services environment.

ABSTRACT

The management of telecommunication and data networks has been based on standards defined in historical contexts quite different than the current times. As a consequence, traditional management technologies are not able to address important challenges posed by the modern infrastructures. Web Services technologies enable the proper communication of processes deployed on quite hostile environments such as the Internet. The use of Web Services for management allows the integration of low-level activities (e.g., retrieving monitoring information from gateways) with high-level business processes (e.g., creating a new product and its marketing strategy.) Despite clear advantages, Web Services-based management does not come for free; since Web Services are based on XML documents, its performance, compared with traditional management technologies, may represent an important drawback. This chapter covers the aspects of using Web Services for management focusing on the different interactions between managers and devices and the performance associated with it.

DOI: 10.4018/978-1-60566-194-0.ch046

INTRODUCTION

For more than ten years the Simple Network Management Protocol (SNMP) (Case, 1990) has been used to manage networks and services. Standardized by the Internet Engineering Task Force (IETF), SNMP is not only a protocol itself but a whole management framework widely recognized and accepted by both academia and industry. Despite its evolution through the definition of SNMPv2 (Presuhn et al., 2002) and SNMPv3 (Harrington et al., 2002), the SNMP framework still has restrictions that prevent its integration with other critical disciplines, such as e-Business, e-Learning, and e-Government. For example, since SNMP traffic is normally blocked by Internet firewalls, is it not possible for different companies to exchange management information via SNMP. Also, SNMP data is encoded following rules quite different than those based on XML (eXtensible Markup Language), normally used by e-Business solutions. Thus, although SNMP could technically be used in other fields, the framework restrictions make SNMP feasible almost exclusively for network management.

Recently, the Web Services (WS) technology has emerged as an interesting and promising management alternative that could overcome some of the SNMP problems. However, since Web Services are younger than SNMP, investigations are being carried out in order to understand the difficulties and the impact in adopting Web Services for management. First investigations in this field were more focused on the network bandwidth consumption (Neisse et al., 2004) because Web Services, which are based on XML, intuitively would consume more bandwidth than SNMP, which is a binary protocol with messages supposedly smaller. Next, response time and other performance aspects such as memory consumption and processing have been investigated as well (Dreves et al., 2004) (Pavlou et al., 2004), again because in comparison to SNMP, Web Services potentially would require more memory and processing power to store and parser XML structures.

Technically, Web Services could completely replace SNMP, but that is not actually feasible because network operators would not instantaneously upgrade or replace the already deployed SNMP-enabled devices and services just because a new management framework, based on Web Services, is available. However, solely using SNMP would not allow the integration of network management-related tasks with other tasks required by those disciplines cited before. Therefore, an intermediate approach is required in order to integrate "legacy" devices and services into Web Services-based systems. That can be successfully accomplished by the use of Web Services gateways.

Gateways have been around in the network management field almost since the beginning of SNMP. CMIP (Common Management Information Protocol) to SNMP (Saydam et al., 1998) and CORBA (Common Object Request Broker Architecture) to SNMP (Aschemann et al., 1999) are examples of gateways investigated in the past whose objective was to integrate SNMP with other technologies, in this case, CMIP (OSI, 1991) defined in the ISO/OSI management framework, and CORBA (Orfali et al., 1998). The interesting point regarding gateways for Web Services integration is that they can be designed and built using different approaches, and each design approach impacts not only on the gateway building process itself, but also on the performance of the underlying managed network and associated management system.

In this chapter we present and discuss the different approaches for Web Services for management integration, namely protocol-level, object-level, and service-level gateways. We show how SNMP-enabled devices can be effectively integrated into Web Services-based systems in a feasible fashion. The discussion about the approaches for Web Services to SNMP gateways is also presented. The gateways approaches are evaluated considering a set of evaluation parameters, such as gateways' ease of use and gateways' response time.

BACKGROUND

As mentioned before, gateways in network management have been around since the SNMP beginning. Gateways based on XML and Web Services technologies, however, are more recent.

Oh *et al*. (2002) defined SNMP to XML gateways and three methods for interactive translation: DOM (Document Object Model)-based translation, HTTP (HyperText Transfer Protocol)-based translation, and SOAP (Simple Object Access Protocol)-based translation. In the DOM-based translation, an XML-based manager calls a DOM interface that resides in the gateway. Such call is then translated to SNMP operations between the gateway and the target device. With the HTTP-based translation the gateway receives XPath and XQuery expressions defined by an XML-based manager. Such expressions are then translated to SNMP requests. Finally, in the SOAP-based translation the gateway exports more sophisticated services accessed by the XML-based manager. With these services the manager can look up information with XPath or proceed with complex queries through XQuery expressions.

Strauss and Klie (2003) have proposed an SNMP to XML gateway similar to the HTTP-based translation method of Oh *et al*. The gateway accepts HTTP messages with XPath expressions in the URL. The XPath expressions are then verified to be translated to SNMP messages. DOM is then used to access the XML documents inside the gateway, reducing the data transferred between the XML-based manager and the gateway. To cope with configuration management, HTTP POST messages are translated to SNMP Set requests.

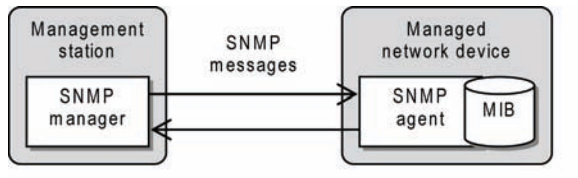
Neisse *et al*. have implemented a system that automatically creates SNMP to XML gateways given an SMI (Structure of Management Information) MIB (Management Information Base) file (Neisse et al., 2003). The gateways created retrieve information from target SNMP devices and generate XML documents sent back to an XML-based manager to be further parsed and analyzed. As the work of Strauss and Klie before, the translation is executed through the help of the smidump tool (Strauss 2003).

The work that has been done up to today uses just a subset of the facilities found in the WS architecture. As verified, gateways are created to access SNMP-based devices and export management information on XML documents (real WS, based on SOAP, are barely used). Besides, the WS description through WSDL (Web Services Description Language) and its registration in UDDI (Universal Description, Discovery and Integration) are not addressed in the work done so far. In addition, these investigations presented in this section do not address the diversity in building and using the developed gateways, which is critical for their proper use in real environments.

THREE APPROACHES FOR WEB SERVICES GATEWAYS

The typical management framework (which SNMP follows) is basically composed by four main elements: manager, agent, protocol, and management information base. The **manager**, from a management station, accesses the management information base (**MIB**) of a managed device contacting, via the management protocol, a protocol **agent**, usually located inside the target device. SNMP defines protocol operations to retrieve (*e.g.*, Get, GetNext) and modify (*e.g.*, Set) management information. Management information is defined in **MIB modules** written in plain text files according to the SMI (Structure of Management Information) (Mccloghrie 1999) specification, which is a subset of the ASN.1 (OSI 1987) language. The management information defined in a MIB module, and the way such information must be handled, defines the

Figure 1. An SNMP manager contacts an SNMP agent via SNMP messages to read or modify the managed network device MIB



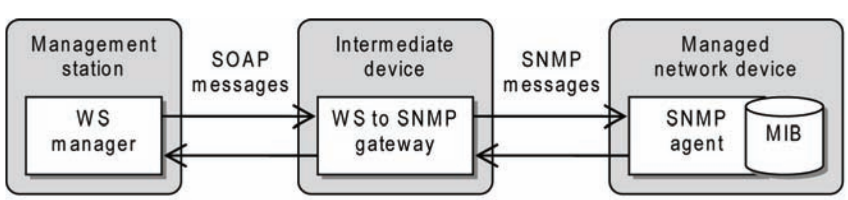
management services offered by the managed device. Figure 1 shows a conceptual view of the general SNMP framework. Further details about SNMP are available in IETF documents at http://www.ietf.org.

Two aspects of the classical management framework are important for Web Services (WS) integration. First, the SNMP framework explicitly separates the definition of the management information from the protocol that manipulates it. Second, the SNMP agent is usually just a means to access devices' MIBs through the management protocol, but it is not an active entity in the sense that it does not take any management decision based on the values of the management information. Rather, the manager is the entity responsible for analyzing the management information of a device in order to proceed with management actions, *i.e.*, management processing power is heavier at the manager side than at the agent side. The introduction of an intermediate gateway between manager and agent does not only provide the required WS to SNMP translations, but also allows balancing the processing power needed to manipulate the management information between the manager and the new introduced gateway.

In order to accomplish a WS-based management solution, the traditional SNMP manager is replaced by a WS manager, which is a WS-based client application that needs to retrieve management information from SNMP-enabled devices. A WS to SNMP gateway is placed between the new WS manager and the traditional SNMP agent in order to translate the WS manager requests to SNMP requests, and to translate back the SNMP agent replies to WS replies sent to the WS manager. In addition, WS interactions between manager and gateway are accomplished by SOAP (Simple Object Access Protocol) (Gudgin et al., 2003), which is currently the most used protocol for WS communication. Figure 2 presents the management scenario where a WS to SNMP gateway is deployed.

The creation of WS to SNMP gateways can be accomplished via different approaches, as pointed before. In the following subsections we present three main approaches. In one of them, we assume the use, at the managed device, of the Script MIB specification as an example of a more sophisticated management service. The Script

Figure 2. A WS manager contacts, via SOAP messages, a WS to SNMP gateway in order to access the SNMP agent of the end managed device



MIB (Schoenwaelder et al., 2000) is a MIB module that defines management information required to allow the transferring and remote execution of management scripts on target devices. With such MIB module a manager can send a management script to a remote device and request it to execute the transferred script. The results of the execution are then later retrieved by the manager also using the Script MIB.

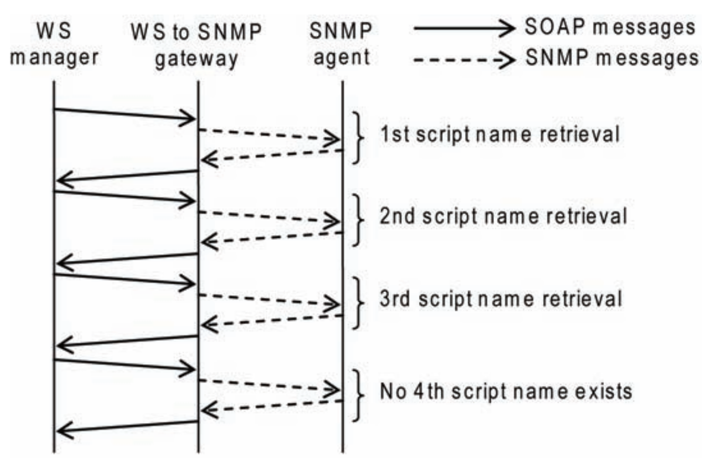
Protocol-Level Gateways

Protocol-Level gateways (Schoenwaelder et al. 2003) provide communications between WS managers and SNMP agents via protocol translations, *i.e.*, SNMP messages are directly mapped to WS operations. For example, the SNMP messages Get, GetNext, and Set are mapped to exactly other Get, GetNext, and Set WS operations. In such a mapping, most data required to build up an SNMP request is provided in input arguments of the WS gateway operations. On the way back, most data carried by an SNMP response become either the WS operation results or output parameters.

A protocol-level gateway receives SOAP requests from a WS manager and translates it to SNMP requests forwarded to the target devices. After processing the request, the target device sends back to the gateway SNMP replies that are translated to SOAP replies forwarded to the WS manager. Figure 3 shows the interactions in a scenario where a protocol-level gateway is deployed and a WS manager needs to know the name of the management scripts available in the target device. In this example, the end device hosts three management scripts. Since SNMP discovers the end of a list receiving an inadequate reply after the last element, to retrieve the name of all management scripts (*i.e.*, three names), four interactions are required.

In SNMP, each management object has an object identifier (OID), which is a sequence of integers used to address the information. For example, the smScriptName object of the Script MIB has OID “1.3.6.1.2.1.64.1.3.1.1.2.” OIDs are used by SNMP managers to inform SNMP agents about the internal data to be retrieved or modified. In the case of the protocol-level gateway, the WS manager still deals with OIDs to manage the target devices. Hence, OIDs are carried by SOAP messages from the WS manager and gateway, and by SNMP messages between gateway and SNMP agent.

Figure 3. In protocol-level gateways, each SNMP message corresponds to another SOAP message



Object-Level Gateways

Instead of translating protocol operations, object-level gateways (Neisse et al., 2004) map management information to a WS operation. For example, instead of exposing a GetNext operation, an object-level gateway for the Script MIB would expose a GetSmScriptName operation to list the scripts available for execution. The GetSmScriptName operation is a mapping of the smScriptName object defined in the Script MIB.

It is important to notice that in this case the WS manager does not need to deal with SNMP OIDs anymore. The object-level gateway implementation stores the required OIDs in order to use them once the WS manager requests a device's information. Another important point is related to the retrieval of management information. In the case of the object-level gateway the gateway itself, and not the WS manager, controls the interactions with the SNMP agent required to retrieve all data from a list, builds up the SOAP reply, and sends it back to the WS manager. This interaction control, which would be performed by the manager in the protocol-level gateway, is then moved to the object-level gateway, introducing a certain level of control on the gateway side.

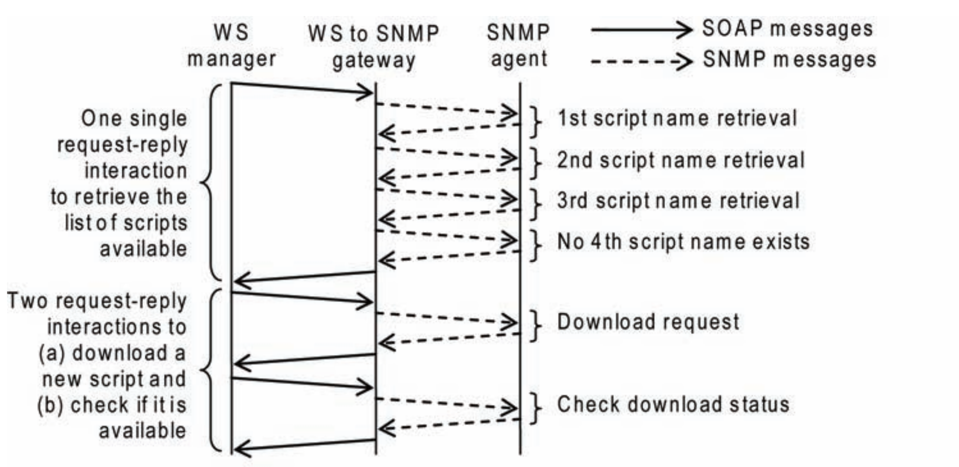
In comparison to Figure 3, Figure 4 shows that WS manager and gateway have fewer message exchanges when the object-level gateway is used. Figure 4 additionally shows the interactions needed to order the target device to download (from an external server not depicted in the figure) a management script, and associated retrieval of the download status. The example of Figure 4 deals with three different objects defined in the Script MIB: a list of scripts (smScriptName), an object to inform the management script location (smScriptSource) from where the target device must download it, and an object that reports the download status (smScriptAdminStatus).

Service-Level Gateways

As presented before, the set of management information defined in a MIB module ends up providing a management service available at target devices. Service-level gateways (Fioreze et al., 2005) are those that map the management services of a MIB module.

Let's consider again the Script MIB module, which defines a set of objects that need to be manipulated in order to transfer a management script from an external server to the managed device. Such objects need to be handled in a co-

Figure 4. In object-level gateways, one WS operation may be associated to several SNMP messages



ordinated way; otherwise the download operation may fail. Although a MIB module defines the managed information in a formal way in SMI, the management service exposed by a MIB module is defined informally in the comments clauses of each object. It means that the way and order in which each Script MIB object must be manipulated to properly download a script is informally defined in the Script MIB objects comments.

Service-level gateways are built in an empirical fashion because there is no concrete element (*e.g.*, protocol or management information) able to formally define the services exposed by a MIB module. For example, the set of Script MIB objects that supports the download request, checking, and execution of a management script could be mapped to a single WS gateway operation, as presented in Figure 5.

Although building up service-level gateways is not done on top of formal basis, its usage from the WS manager is easier because such manager does not need to know neither the managed device OIDs (as in the protocol-level gateways) nor how a set of objects needs to be manipulated in order to have a management services properly working (as in the case of the object-level gateways).

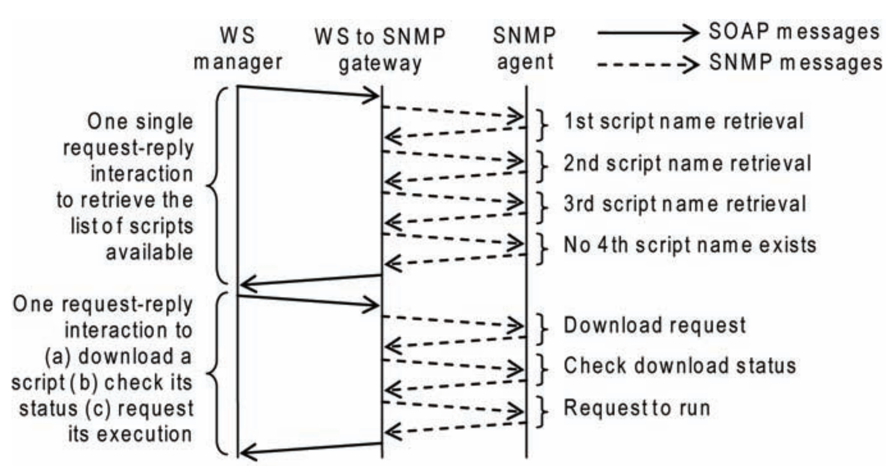
PERFORMANCE OF WEB SERVICES-BASED MANAGEMENT APPROACHES

In this section we present the performance of the three WS to SNMP gateways presented before in order to characterize them in terms of network bandwidth consumption, perceived execution time, effort to maintain, and ease of use. These parameters not only allow determining the gateways' behavior and characteristics but they also indicate the management scenarios that each gateway is more suitable for.

Consumed Network Bandwidth

Network consumption is critical for management because usually the bandwidth available for network users' traffic is shared with management traffic. If management traffic grows too high, less bandwidth is available to users, which is obviously inadequate. SNMP is a quite light protocol considering the bandwidth consumed to carry the management information. SOAP, however, has messages longer than SNMP because SOAP is based on XML. This difference could lead to the conclusion that WS manager and gateway inter-

Figure 5. In service-level gateways, one WS operation may be associated to several SNMP interactions and objects in order to have a management service accomplished



actions consume more bandwidth than gateway and SNMP agent interactions. That is true for the protocol-level gateways, where each SNMP message corresponds to exactly another SOAP message, but it is not always true for object and service-level gateways.

Let's observe the bandwidth consumed by the three approaches considering two management scenarios. In the first one, a WS manager interacts, in different moments, with a protocol-level and an object-level gateway in order to retrieve a list of integer objects defined only for the purpose of this test, *i.e.*, the meaning of the returned integers is not important, but the bandwidth consumed. We start with a single one integer object and progressively increase the testing list until 70 single integer objects are retrieved, and measure the network usage between the WS manager and the gateway, and between the gateway and the SNMP agent. The testing network in this first scenario is identical to the one presented in Figure 2, *i.e.*, protocol-level and object-level gateways are dedicated machines placed between manager and agent.

The graph from Figure 6 presents the network usage for the SNMP traffic and SOAP traffic running over HTTP and HTTPS (for the case of required security support). Since intuitively SOAP would consume more bandwidth than SNMP, compressed SOAP traffic has been also observed to check how much the bandwidth consumption could be decreased. As shown in the graph, SNMP traffic will always consume far less bandwidth than SOAP, even if SOAP compression is present. This situation gets even worse when the number of objects to be retrieved increase: since each SOAP message consumes more bandwidth than the associated SNMP message, the higher the number of messages, the greater the difference between SOAP and SNMP.

By replacing the protocol-level gateway for an object-level gateway, we have the bandwidth consumption presented in Figure 7. In this case, although initially SOAP traffic (over HTTP or HTTPS, and compressed and uncompressed) consumes more bandwidth than SNMP, if more objects are retrieved from the managed device SOAP traffic will eventually consumes less bandwidth

Figure 6. SNMP traffic always consumes less bandwidth than protocol-level gateway traffic, even when SOAP compression is used

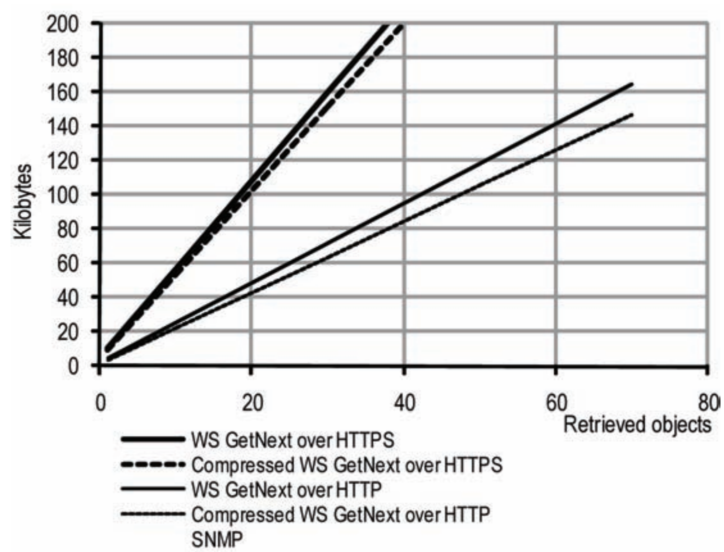


Figure 7. Since the object-level gateway can group SNMP retrieved information in a single SOAP reply, at some points total SOAP traffic will consume less bandwidth than SNMP traffic

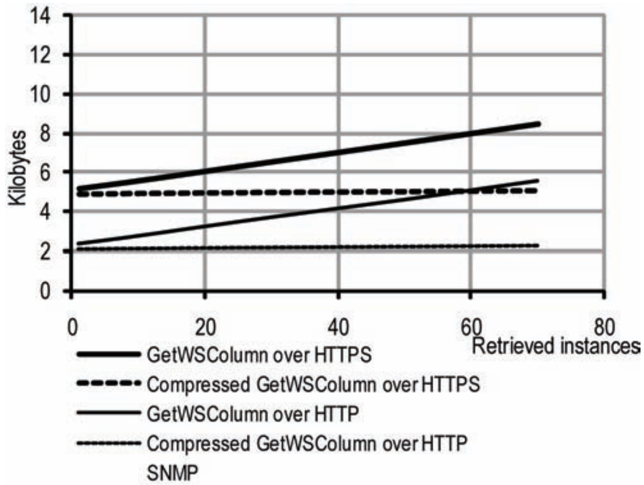

Figure 8. Scenario for the object-level and service-level gateways

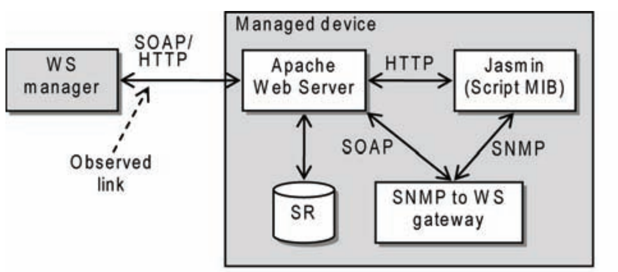


than SNMP. That happens because the object-level gateway groups all SNMP retrieved information from the target device in a single SOAP reply. Thus, there is only one SOAP request and associated reply, while several SNMP interactions are present, as has been depicted in Figure 4.

By reviewing the graph from Figure 7 it is possible to conclude, for this first scenario, that uncompressed SOAP over HTTPS traffic consumes less bandwidth than SNMP if a list with more than 38 integers needs to be retrieved. Compressed SOAP over HTTPS traffic is "better" than SNMP if more than 26 integers are retrieved. Uncompressed SOAP over HTTP traffic consumes less bandwidth than SNMP after 17 integers, and compressed SOAP over HTTP after 11 integers. It is interesting to notice that for more than 68 integers, compressed SOAP over HTTPS traffic consumes less bandwidth than uncompressed SOAP over HTTP. In general, the introduction of compressing makes the SOAP traffic line angle to slow down, while the introduction of security support via HTTPS makes the SOAP traffic line initiate at a higher value.

In order to check the bandwidth consumed by service-level gateways, we put them in perspective with object-level gateways in a second scenario, where we turn back to our previous Script MIB cases. In this scenario, presented in Figure 8, we placed both gateways and SNMP agent inside the same target device. Although this configuration does not affect the bandwidth evaluation, it has important impact on the response time, to be presented in the next subsection.

In this scenario, the the WS to SNMP gateway is coded using the nuSOAP library for PHP. The target device is a Linux-based host running the Apache Web server, a local management script repository (SR), and the Jasmin tool. Jasmin (Braunschweig, 2003) is an implementation of the Script MIB developed by the Technical University of Braunschweig and NEC C&C Research Laboratories. Jasmin implements the Script MIB published in the RFC 2592, which was later updated by the RFC 3165. Jasmin supports the Java and TCL runtime engines, so that network managers can delegate Java and TCL management scripts to the Jasmin-enabled end device.

The interactions on this scenarios works like this. The WS manager builds up an SOAP/HTTP request sent to the target device's Apache server, which removes the HTTP information and delivers the SOAP request to the internal WS to SNMP gateway. The gateway contacts, using SNMP, the Jasmin agent to request Script MIB operations. One operation is the download of a management script from the Jasmin agent. Since our script repository (SR) is internal to the local device, once Jasmin is required to download a script it locally contacts the Apache Web server in order to download, via HTTP, a management script from the SR.

In this scenario the following management actions are executed:

- The manager orders the SNMP agent to download a management script named wait.jar;
- The manager blocks until the SNMP agent finishes the script download from the local repository SR;
- The manager blocks again until wait.jar is ready to run;
- The manager requests the execution of wait.jar passing as input argument the number of seconds wait.jar must wait until its end (0, 5, 10, and 15 seconds are considered);
- The manager blocks again until the execution of wait.jar is over;
- Finally, the manager retrieves the execution results from the target device.

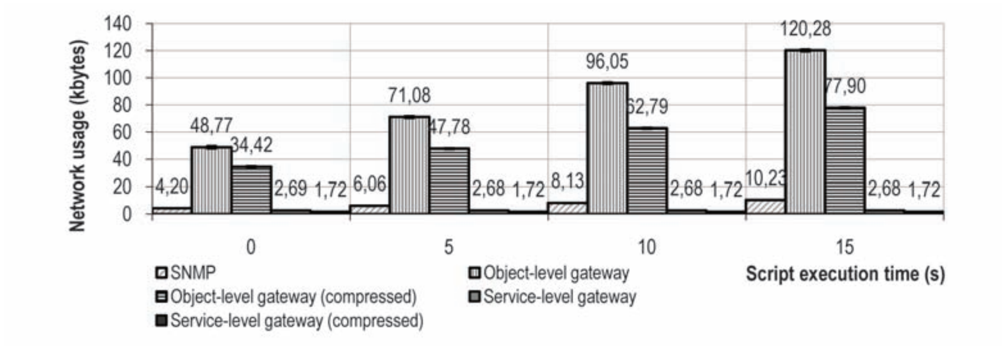
Although not explicitly shown on Figure 8, two different managers are in fact considered: a WS manager and an SNMP manager. The WS manager interacts with the WS to SNMP gateway, while the SNMP manager interacts directly with the Jasmin agent, skipping the WS to SNMP gateway. With these two managers it is possible to compare the bandwidth consumed by SOAP and SNMP to accomplish the management actions defined previously.

One important difference distinguishes the object-level and service-level gateways: in the object-level gateway the WS manager controls each step, while in the service-level gateway the gateway itself controls all steps and the WS manager just needs to order the executions of the steps to the gateway. If instead of using a WS manager one uses an SNMP manager, then the SNMP manager will behave like the WS manager in the object-level gateway, since the SNMP manager will be the one responsible for controlling the execution of the management steps.

In the second scenario, only compressed and non compressed HTTP traffic is observed; HTTPS is not considered because, in comparison, compression has a stronger impact than HTTPS on the final bandwidth consumed. Figure 9 shows the bandwidth consumed by SNMP in a direct SNMP manager-agent interaction, and by WS manager and WS to SNMP object-level and service-level gateways.

According to the previous testing steps, the (WS or SNMP) manager blocks in three moments: when it waits for the wait.jar script to be downloaded, when it waits for the script to be

Figure 9. Object-level gateway, for different actions, consumes more bandwidth than SNMP, while service-level gateway, that aggregates SNMP information in a single SOAP request-reply interaction, consumes less bandwidth



ready to run, and when it waits for the script to finish its execution. To implement such blocking, the SNMP manager for the Script MIB and WS manager for the object-level gateway loop until they get a proper confirmation from the target devices indicating that the script is downloaded, ready to run, or finished.

From Figure 9, SNMP consumes far less bandwidth than the object-level gateway, but more bandwidth than the service-level gateway. In the case of the service-level gateway, no loop is required in the manager because the gateway itself blocks until the script results are available. Thus, the testing loop has been moved from the WS manager to the service-level gateway, then consuming less bandwidth. Figure 9 also shows the bandwidth consumed when the SOAP/HTTP traffic is compressed. As observed, and intuitively believed, less network resources are consumed when compression is used because compressed SOAP/HTTP messages are smaller than the uncompressed ones.

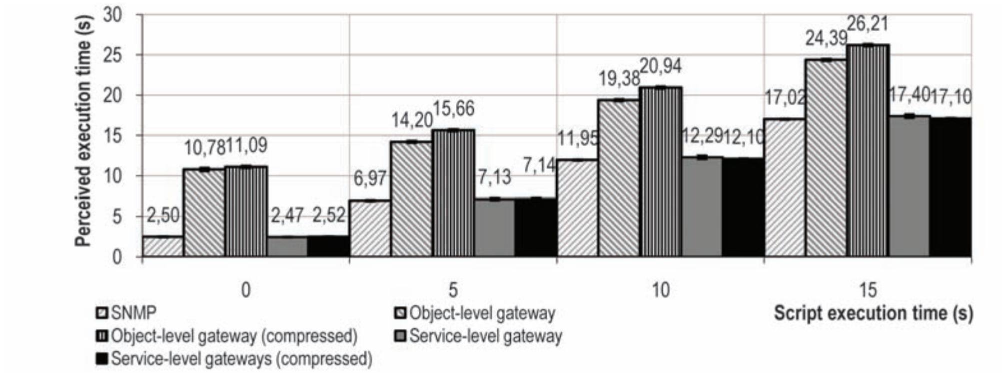
It is important to note that although object-level gateway consumes less bandwidth than SNMP in the first evaluation scenario, but more bandwidth than SNMP in the second scenario, this difference is not inconsistent. In the first scenario the object-level aggregates SNMP information in a single SOAP reply because the information being retrieved was a list of elements associated to the same object (a testing list of integers), while in the second scenario the SNMP information (objects) was different from each other, preventing the object-level gateway to aggregate them. That aggregation, however, was possible in the service-level gateway, which then consumed less bandwidth.

Perceived Execution Time

The perceived execution time is defined as the time when a manager perceives that a management task is over. That is different to the real execution time, since a management task may finish at a time, but perceived as so by the manager at a later instant. Perceived execution time is an important metric because managers take management actions normally based on the results of previous actions. If the perceived execution time is high, the management actions are delayed in the management station. Ideally, the perceived execution time should be as close as possible to the real execution time.

To check the perceived execution time, we have used the second evaluation scenario presented in the bandwidth evaluation. We have measured the execution time to download, execute, and retrieve the results of the wait.jar management

Figure 10. The execution time of actions executed through object-level gateways (with or without compression) take longer to be perceived than in the case of SNMP, while in for service-level gateway the perceived execution time is similar to SNMP



script using, again, an SNMP manager, and two WS managers for the object-level and service-level gateways. Figure 10 presents the measured perceived execution times.

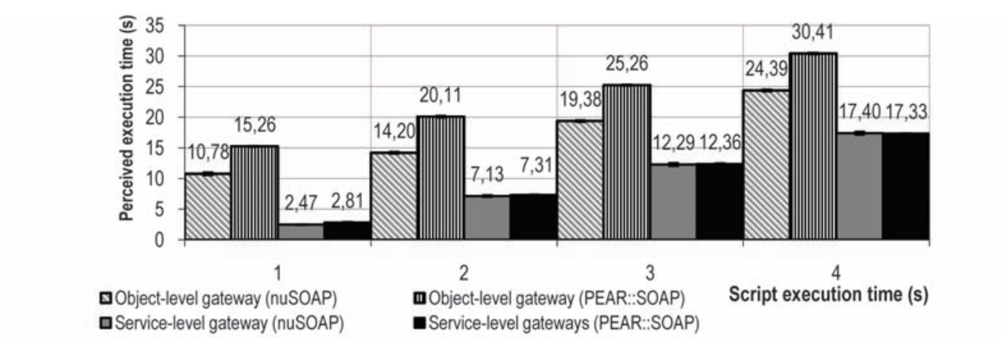
One aspect that influence in the perceived execution time is the set of software libraries used in the management system. As pointed before, we have been using the nuSOAP library to support Web Services in the PHP scripting language. In order to compare how SOAP libraries impact in the perceived execution time, we have re-implemented the service-level gateway now replacing nuSOAP by PEAR::SOAP, which is a second library for SOAP support in PHP. Figure 11 presents the results on using service-level gateways implemented using nuSOAP and PEAR::SOAP.

As can be observed, PEAR::SOAP tends to impose a greater perceived execution time, especially in the case of object-level gateways. This is so because PEAR::SOAP has a processing delay greater than nuSOAP, then taking more time to encode and deliver the SOAP/HTTP messages to the WS manager.

Maintenance Effort and Ease of Use

WS to SNMP gateways need to be maintained in order to properly follow the changes in the target device MIB structure. Gateways need also to be updated if they are supposed to access new

Figure 11. Generally, PEAR::SOAP, compared with nuSOAP, results in a greater perceived execution response time



target devices with different MIBs than the MIBs of previous managed devices. In addition, different gateways have different ease of use from the WS manager perspective, *i.e.*, WS managers face different level of easiness in dealing with different gateways. In this subsection we check the maintenance effort and the ease of use of the three WS to SNMP gateway approaches. Concerning the ease of use aspect, we take the approach of observing the gateways from a WS manager perspective, which is different than the perspective of an SNMP manager, since SNMP managers are aware of the SNMP technology, but WS managers are not.

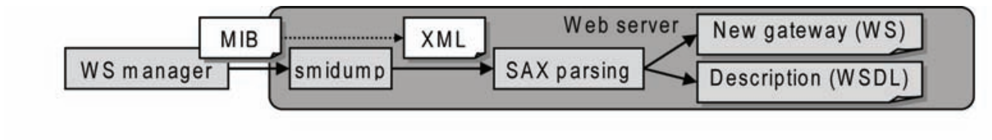
In the standard SNMP framework, managers require maintenance effort in order to keep in tune with the management information of target devices. SNMP manager maintenance is accomplished informing the manager about new management information using the MIB modules that describe this new information. Usually, when the manager needs to support a new device, the network human operator downloads, from the devices manufacturer Web site, MIB module files that specify the information available at the target device, and installs these modules in the manager. From this installation on, the SNMP manager is aware of the available information and can properly access and manipulate it on the target device.

Protocol-level gateway is not aware about the information being requested to the target device: it only translates requests from SOAP to SNMP and back. In this way, if new management information is available at the target device, actually the WS manager needs to be updated, not the protocol-level gateway. Thus, once built, protocol-level gateways require no maintenance effort, considering the changes in the MIB of target devices. On the other hand, protocol-level gateways are not easy to use to WS manager. Protocol-level gateways expose operations (*e.g.*, Get, GetNext, Set) that forces the WS manager to known the SNMP information peculiarities in order to deal with them. Thus, WS managers using protocol-level gateways are forced to be SNMP aware, which is not simple. Since dealing with SNMP information (*e.g.*, OIDs) is complex, protocol-level gateways are not easy to use too.

Object-level gateways, concerning their maintenance effort, do require to be updated as soon as new information is available on target devices. This is so because the set of management information defines the WS operations exposed by the object-level gateway. If new information is included in the target device, but the gateway is not updated, the information will be unavailable for the WS manager. In this case, the WS manager will be able to access only the information that has a corresponding WS operation on the object-level gateway.

Although object-level gateways require maintenance efforts, this can be automated via supporting software able to parse and process MIB module files and generate associated gateways. Since MIB modules are defined using the SMI precise rules, one can access its content and produce outputs results convenient for specific applications, that in our case corresponds to the creation or update of object-level gateways. Figure 12 presents the architecture of an object-level gateway building system developed for this investigation. The first step in a gateway creation is the transfer of a MIB module from the WS manager to the Web server trough HTTP or HTTPS. Internally on the server, the smidump tool checks the received MIB module and, if no inconsistencies are found, it generates an XML temporary document. The smidump tool (Strauss, 2003), developed at the Technical University of Braunschweig, is a whole MIB module checking and manipulating system able to translate MIB modules to other representations, including XML. The next SAX (Simple API for XML) parsing step, in turn, takes the XML temporary document to build up the new gateway. Each object in the original MIB module is transformed in operations of the new generated WS. These operations are instrumented with code

Figure 12. The object-level gateway building system receives a MIB module files and generates, after some intermediate steps, a new gateway and corresponding WSDL document



able to contact, via SNMP, a target device. The just created gateway is then stored in a standard directory in the Web server and available to be invoked just after its creation. At the same time the parsing step creates the code for the new WS, it also builds the WSDL document that describes the created WS. The WS-based manager that requested the creation of the new object-level gateway optionally informs the URL of a UDDI repository where the created gateway is registered. The original MIB module file provided by the WS manager is also stored in another standard directory for documentation purpose, as well as the intermediate XML document generated by the smidump tool prior to the parsing step.

With this gateway building process, new MIB modules can be easily added to a WS-based management environment. In order to let this process works properly, however, the original MIB module files should be correctly defined. It is not rare to find MIB module files that have definition problems (mainly old MIB files, since more recent MIB modules seem to be more properly defined). For example, according to the output of the smilint tool, the RFC1213-MIB module has 3 errors (Fenner, 2003). In the case of finding MIB definition problems, the intended WS to SNMP gateway will not be created, and the corresponding smidump message describing the errors found will be sent back to the WS-based manager. It is important to notice that the gateway building system itself is not a WS, but a Web application running at the same Web server that will host the gateways just created.

In terms of ease of use, object-level gateways are more interesting than protocol-level gateways. Since SNMP management information is mapped to WS operations, SNMP details are hidden by the object-level gateway from the WS manager. Although still dealing with management information at some level, WS managers do not need to know, for example, how to manipulate SNMP OIDs in order to retrieve data from the target devices. Given that the object-level building process presented before generates an associated WSDL document, WS managers can be aware of the new management information whenever the target device MIB is updated (and an associated gateway built). The important point is that the WS manager is not forced to deal with MIB modules files, *i.e.*, WS managers do not need to be SNMP aware anymore.

Service-level gateways, compared with protocol-level and object-level gateways, require far more efforts to be maintained. As presented before, service-level gateways are not built upon formal basis (protocol or MIB module definition), but rather based on the services exposed by a MIB module which are defined in the MIB module comment clauses. It means that for every new MIB module available that requires a service-level gateway, such gateway will be developed manually checking the MIB module content to produce a set of WS operations. The developer (or the designer) of service-level gateways is the one responsible for mapping the original MIB module into the gateway operations. That means that two different developers (or designers) will probably end up with different gateways for the same original MIB module.

Since the services are not formally defined, there is no current tool able to, given a MIB module, automatically produce a new service-level gateway, as it was the case for object-level gateways presented before. Thus, for each new MIB module available, the developer has to built the associated service-level gateways, which is a slower process if we compare with the object-level gateways (that are automatically created via a building system) and protocol-level gateways (that need to be implemented just once, regardless the changes in the MIBs of target managed devices).

However, regarding ease of use, service-level gateways are quite interesting because besides hiding SNMP details from the WS manager (as object-level gateways do), service-level gateways also hide the steps required to accomplish a specific management service defined in a MIB module. While in the object-level gateway the WS manager needs to know what WS operations must be called and in which order, in the service-level gateway the WS manager only needs to invoke a WS operation that corresponds to a whole management service. Surely, this ease of use depends on the quality of the mapping of the MIB service to the service-level gateway, but in general it is safe to say that even for bad mappings the service exposed by a service-level gateway is easier to use than the corresponding whole set of operations exposed by an object-level gateway.

In order to summarize the evaluation of the WS to SNMP gateways, table 1 puts the three approaches in perspective regarding the evaluation parameters consumed bandwidth, perceived execution time, maintenance effort, and ease of use.

CONCLUSION

In this chapter we have evaluated three different approaches for building Web Services (WS) to SNMP gateways. Such gateways are required for the integration of traditional network devices into WS-based systems, such as systems for e-commerce and e-government. Protocol-level gateways directly map SNMP messages to SOAP messages, while object-level gateways hide SNMP details from WS managers offering WS operations mapped from MIB modules. Finally, service-level gateways go further and expose management services instead of management information (like object-level gateways) or protocol mapping (like protocol-level gateways). However, service-level gateways are more difficult to maintain because they require the human interpretation of MIB modules to build up a new version of the gateways when the set of management information is changed. Object-level gateways, on the other hand, can be automatically built given a MIB module as input argument, while protocol-level gateways do not require maintenance efforts at all because their operation is not affected by changes in the management information available at the target devices.

Protocol-level gateways are interesting in

Table 1. Summary on WS to SNMP gateways evolution

Gateway	Bandwidth	Execution time	Maintenance	Ease of use
Protocol-level	Gateway with highest bandwidth consumption	Takes more time than SNMP to learn that a task is over	After being built, requires no maintenance at all	Difficult to use because forces WS managers to be SNMP aware
Object-level	Consumes less bandwidth than SNMP for a large number of objects	Takes far more time than SNMP to learn that a task is over	Easy to maintain given a gateway building system based on MIB modules	Hides SNMP details, but WS managers need to know how to use the service
Service-level	Consumes less bandwidth than SNMP and other gateways	Learns faster than SNMP that a task is over	Difficult to maintain and requires human interpretation of MIB services	Easy to use because service details are hidden from the WS manager

management environment where the set of management information changes quite frequently. Although they consume far more bandwidth than SNMP, protocol-level gateways may enable the communication of manager and agents located in different administrative domains because SOAP traffic tends to cross Internet firewalls easier than SNMP. However, the WS manager must be aware of the SNMP peculiarities in order to interact with the protocol-level gateway, which is an important restriction when dealing with systems of broader disciplines such as e-business.

Object-level gateways are ideal when the amount of information to be retrieved from managed devices is high. Since these gateways are able to group SNMP information in a single SOAP reply, object-level gateways tend to consume less bandwidth than SNMP for a large number of information. That enables protocol-level gateways to be used, for instance, in monitoring system composed of measurement elements deployed in networks located in different administrative domains, and bunches of collected data needs to be transferred from time to time to a central Web Services based analysis tool. Since the maintenance and ease of use of object-level gateways are not complex, the availability of new different management information on the managed network does not lead to complex updates of gateways and WS managers.

Finally, service-level gateways, besides consuming less bandwidth than SNMP and presenting response time close enough to SNMP, has the advantage of being easier to use. Service-level gateways are ideal for integrating SNMP into non network management systems, because these gateways not only hides the SNMP complexities but also exposes management services in a simpler way than the previous gateways. If we do not consider the maintenance effort, the results presented in this chapter help us to argue in favor of a service-oriented SNMP/WS integration, instead of information or protocol-oriented integration. The presented service-level gateway is easier to use (from the manager perspective), consumes less bandwidth than the other gateways, and presents a response time quite close to SNMP. It is important to highlight that these conclusions are based on the case of the Script MIB. However, although the SNMP framework is well known and accepted, designing WS management solutions taking the SNMP framework as a starting point is not a proper approach in modern times. Rather, services must be considered in the first place and SNMP "details" should be treated only when the protocol and related information issues begin to be relevant.

A WS feature that is often cited is that more complex and richer WS can be built from the combination and reuse of other simpler WS. This feature could be used to integrate network management services, or, more interestingly, to create new services that could not be easily built today except through heavy coding efforts. Integrating simpler WS to form richer network management WS is one of the interesting challenges to be addressed. Web Services coordination, orchestration, and choreography applied to the network management field are certainly aspects that must be investigated and considered in the network integration and management field. This is a feasible way to achieve a real and long awaited integration between network management and other Web Services-based disciplines.

KEY TERMS AND DEFINITIONS

Integrated Network Management: The study of integrating network management operations among each other or with other external disciplines.

Network Management: A computer science discipline that investigates activities, methods, procedures, and tools to operate, administrate, maintain, and provide networking infrastructures.

Protocol Evaluation: The observation of a network protocol in terms of its behavior and the impact associated to it over the communication infrastructure.

Protocol Gateway: A software entity able to translate protocol messages, operations, and/or services from one specific protocol to another specific protocol.

SNMP: Stands for *Simple Network Management Protocol* and is the *de facto* standard network management protocol for TCP/IP networks.

Chapter 6.7
Web Services, Service-Oriented Computing, and Service-Oriented Architecture: Separating Hype from Reality

John Erickson
University of Nebraska - Omaha, USA

Keng Siau
University of Nebraska - Lincoln, USA

ABSTRACT

Service-oriented architecture (SOA), Web services, and service-oriented computing (SOC) have become the buzz words of the day for many in the business world. It seems that virtually every company has implemented, is in the midst of implementing, or is seriously considering SOA projects, Web services projects, or service-oriented computing. A problem many organizations face when entering the SOA world is that there are nearly as many definitions of SOA as there are organizations adopting it. Further complicating the issue is an unclear picture of the value added from adopting the SOA or Web services paradigm. This article attempts to shed some light on the definition of SOA and the difficulties of assessing the value of SOA or Web services via return on investment (ROI) or nontraditional approaches, examines the scant body of evidence empirical that exists on the topic of SOA, and highlights potential research directions in the area.

INTRODUCTION

Service-oriented architecture (SOA); Web services; mash-ups; Ajax; Web 2.0; some of their underlying middleware realization schemas such as SOAP (simple object access protocol), UDDI (universal description, discovery, and integration), XML (extensible markup language), and CORBA (common object request broker architecture); and many other ideas or approaches to cutting-edge information system architectures have become the buzzwords of the day for many in the business world and also in the IT and IS communities. It is quite difficult, perhaps nearly impossible, to pick up any relatively current practitioner publication without encountering an article focusing on at least one of the above topics. A recent library database search using keywords *service-oriented architecture, Web services*, and *SOA* resulted in 800-plus returns. Further investigation revealed that roughly 25 of those 800 articles were sourced in research journals while the other (still roughly 800) articles were all from more practitioner-oriented sources.

When it comes to adopting and implementing SOA, it appears that businesses are doing it at astounding rates. Of course, what they are actually doing, even though they may say that their efforts represent a move toward service-oriented architecture, may not match anyone else's definition of SOA but their own. Furthermore, how can SOA be defined, and how can we define the benefits of moving toward such architectures? It seems that there is little agreement among practitioners and researchers alike as to a standard definition of SOA.

Worse still, a growing number of practitioners are now beginning to question the business return of some of the approaches. For example, Dorman (2007), Havenstein (2006), Ricadela (2006), and Trembly (2007) indicate that there is doubt emerging as to the real value of SOA to adopting businesses and organizations. Perhaps the question of return on investment (ROI) should not be that surprising since it sometimes seems that each organization has its own definition of what SOA really is.

This article attempts to reach for a clearer understanding of what SOA really is, and proposes some possible areas of research into SOA that could help clear up some of the definitional confusion, which could in turn help lead to better understanding of ROI as it relates to SOA. First is the introduction. Second, the article provides existing definitions of SOA, Web services, and some of the related and underlying technologies and protocols. The next section combines the various definitions of SOA into a more coherent form, while the section after that proposes ideas about what SOA should be. The fifth section discusses research possibilities and provides recommendations for future research efforts. Next, we look at ways of measuring and justifying SOA and SOC (service-oriented computing) success. Finally, we conclude the article.

BACKGROUND AND HISTORY OF SERVICE-ORIENTED ARCHITECTURE

A minimum of nine formal definitions of SOA exist as of this writing, from sources such as the Organization for the Advancement of Structured Information Standards (OASIS), the Open Group, XML.com, Javaworld.com, Object Management Group (OMG), the World Wide Web Consortium (W3C), Webopedia, TechEncyclopedia, WhatIs.com, and Webopedia.org. In addition, many other definitions put forth by numerous industry experts, such as those from IBM, further cloud the issue, and worse yet, other formal definitions might also exist. In other words, the concept of service-oriented architecture appears in many ways to be a virtually content-free description of an IT-based architecture. It is not our intent here to add yet another definition to this already crowded arena of definitions, but to try to cull the common, base meanings from the various distinct definitions.

Prior to about 2003, the term service-oriented architecture was not in general use for the most part, according to Wikipedia ("SOA," 2007). However, since that time, SOA has exploded nearly everywhere in the business and technology world. SOA appears to derive or develop in many cases from more basic Web services. These services can include enabling technologies such as SOAP, CORBA, EJB (Enterprise Java Beans), DCOM (distributed component object model), and even

SIP (session-initiated protocol) among many others; services may also include other middleware created with XML (Lee, Siau, & Hong, 2003; Siau & Tian, 2004; Sulkin, 2007; Walker, 2007).

Service-Oriented Architecture Definitions

The Open Group (2007) defines SOA as “an architectural style that supports service orientation.” The definition goes on to also include descriptions of architectural style, service orientation, service, and salient features of SOA. OASIS defines SOA as “a paradigm for organizing and utilizing distributed capabilities that may be under the control of different ownership domains.” The OASIS definition includes what they call a “reference model” in which the details of the definition are expanded and formalized. The Object Management Group (2007) defines SOA as “an architectural style for a community of providers and consumers of services to achieve mutual value.” OMG adds that SOA allows technical independence among the community members, specifies the standards that the (community) members must agree to adhere to, provides business and process value to the (community) members, and “allows for a variety of technologies to facilitate (community) interactions” (OMG, 2007).

W3C (2007) defines SOA as “a form of distributed systems architecture that is typically characterized by…a logical view, a message orientation, a description orientation, granularity and platform neutrality.” W3C adds details describing what it means by logical view, message and description orientations, granularity, and platform neutrality. XML.com (2007) defines SOA as follows:

SOA is an architectural style whose goal is to achieve loose coupling among interacting software agents. A service is a unit of work done by a service provider to achieve desired end results for a service consumer. Both provider and consumer are roles played by software agents on behalf of their owners.

The Javaworld.com SOA definition, composed by Raghu Kodali (2005), is as follows: “Service-oriented architecture (SOA) is an evolution of distributed computing based on the request/reply design paradigm for synchronous and asynchronous applications.” Kodali also goes on to describe four characteristics of SOA. First, the interfaces composed in XML, using WSDL (Web services description language), are used for self-description. Second, XML schema called XSD should be used for messaging. Third, a UDDI-based registry maintains a list of the services provided. Finally, each service must maintain a level of quality defined for it via a QoS (quality of service) security requirement.

Finally, IBM proposes that SOA “describes a style of architecture that treats software components as a set of services” (UNL-IBM System in Global Innovation Hub, 2007). Furthermore, it insists that business needs should “drive definition” of the services, and that the value proposition be centered on the reusability and flexibility of the defined services.

SERVICE-ORIENTED ARCHITECTURE

We begin the SOA discussion with an overview of SOA provided by Krafzig, Banke, and Slama (2005). They proposed a three-level hierarchical perspective on SOA in which Level 1 includes the application front end, the service, the service repository, and the service bus (SB). Accordingly, only the service child has children, consisting of the contract, implementation, and interface. Finally, the last level of the proposed hierarchy is composed of business logic and data, children of implementation. The next subsections will discuss the general ideas of the elements included in the hierarchy proposed by Krafzig et al. described previously. This is not to recommend adoption of the hierarchy and description as the final description of SOA, but rather as a framework for discussing the meaning of SOA for the remainder of this article.

Application Front End

This part of SOA comprises a source-code interface, and in SOA terminology, it is referred to as the application programming interface (API). In accordance with most commonly accepted design principles, the underlying service requests, brokerage (negotiation), and provision should be transparent to the end user.

Service Repository

The service repository could be thought of as the library of services offered by a particular SOA. This would likely consist of an internal system that describes the services, and provides the means in the user interface to call a particular service. UDDI could be seen as a realization of the service repository idea. UDDI is a global registry that allows businesses to list themselves on the Internet. UDDI is platform independent and XML based. The point of UDDI is for businesses to list the Web or SOA-type services that they provide so that other companies searching for such services can more easily locate and arrange to use them.

Service Bus

The SB, more commonly referred to as the enterprise service bus (ESB), provides a transportation pathway between the data and the end-user application interface. Using an ESB does not necessarily mean SOA is being implemented, but ESB or some sort of SB use is almost always part of an SOA deployment. According to Hicks (n.d.), Oracle's idea of an ESB includes multiple protocols that "separate integration concerns from applications and logic." What this means is that ESBs have now become commercialized, and can be licensed for use much like other UDDI-based services. So, companies searching for ESB solutions as part of an SOA effort now have multiple choices and do not necessarily have to re-create the wheel by building their own ESB.

Common Services

It seems apparent from many of the SOA definitions that many of the technologies included in an SOA definition, and by default SOA implementations, are established and conventional protocols. To better understand the services provided in many SOA definitions, a brief explanation of some of the more commonly used underlying technologies is provided. A particular service may or may not be explicitly Web based, but in the end it matters little since the services provided by the architecture should be transparently designed, implemented, and provided. The general consensus from most involved in Web services is that the services are meant to be modular. This means that no single document encompasses all of them, and furthermore, that the specifications are multiple and (more or less) dynamic. This results in a small number of core specifications. Those core services can be enhanced or supported by other services as "the circumstances and choice of technology dictate" ("Web Service," 2007).

XML allows users to define and specify the tags used to capture and exchange data, typically between distinct and usually incompatible systems from different companies or organizations. This means that XML is a good example of middleware; it also means that XML enables Web services. XML was one of the initial drivers that provided the ability to conduct e-business for many businesses in the Internet era. XML cannot really be considered a service, but as the language used to write many of the Web services or service stack protocols.

SOAP, like all protocols, consists of a set list of instructions detailing the action(s) to be taken in a given circumstance. SOAP is designed to call, access, and execute objects. The original SOAP was typically for communications between computers, and usually involved XML-based messages.

SOAP and its underlying XML programming comprised one of the first Web service communication stacks. One of the original Web services that SOAP provided was called remote procedure call (RPC), which allowed a remote computer to call a procedure from another computer or network. More recently, SOAP has taken on a somewhat modified meaning so that the acronym now means service-oriented architecture protocol. In both cases, what SOAP does is to use existing communications protocols to provide its services. The more common early SOAP contracts included XML applications written for HTTP (hypertext transfer protocol), HTTPS (HTTP over secure socket layer), and SMTP (simple mail transfer protocol), among others. It should be apparent from these that many early SOAP implementations involved e-commerce or e-business applications, which means that the concern at the time when many applications were first developed was to move sales and other data collected in Web portals to back-end data stores.

CORBA is an OMG-developed standard that allows different software components that are usually written in different languages and installed on different computers to work together (Zhao & Siau, 2007). CORBA was developed in the early 1990s, and while not overtly an SOA at the time, it actually performs many of the functions in an SOA, using an IIOP- (Internet inter-orb protocol) based service stack.

EJB is a component typically situated on the server that "encapsulates the business logic of an application" ("EJB," 2007). EJB enables the creation of modular enterprise (and other) applications. The intent of EJB is to facilitate the creation of middleware that acts as a go-between tying front-end applications to back-end applications or data sources.

SIP is a signaling protocol designed for use in telecommunications at the application layer. It has generally become one of the primary protocols used in VoIP (voice over Internet protocol), H.323, and other communications standards. SIP can be seen as a primary provider of Web services for Internet-based voice communications such as VoIP (Sulkin, 2007).

Contract (Services)

Components of a service contract typically include primary and secondary elements. The primary elements consist of the header, functional requirements, and nonfunctional requirements. Subelements for the header consist of the name, version, owner, RACI, and type. Under functional requirements are functional requirement descriptions, service operations, and invocation. Nonfunctional requirements include security constraints, QoS, transactional requirements (the service part of a larger transaction), service-level agreement, and process ("SOA," 2007). The contract generally includes metadata about itself, who owns it, and how it is brokered, bound, and executed.

Interface

At this level of service provision, the interface referred to is a segment of code that connects the service with the data and/or business logic (process). The interface describes how data will be moved into and out of the data source by the service, and must be designed to comply with the physical (data, data structures, etc.) and process (business logic) requirements of the existing and/or legacy system.

Implementation

The implementation specifies the contract and interface to be used for each service requested, and contains the direct pathway into the data and business logic.

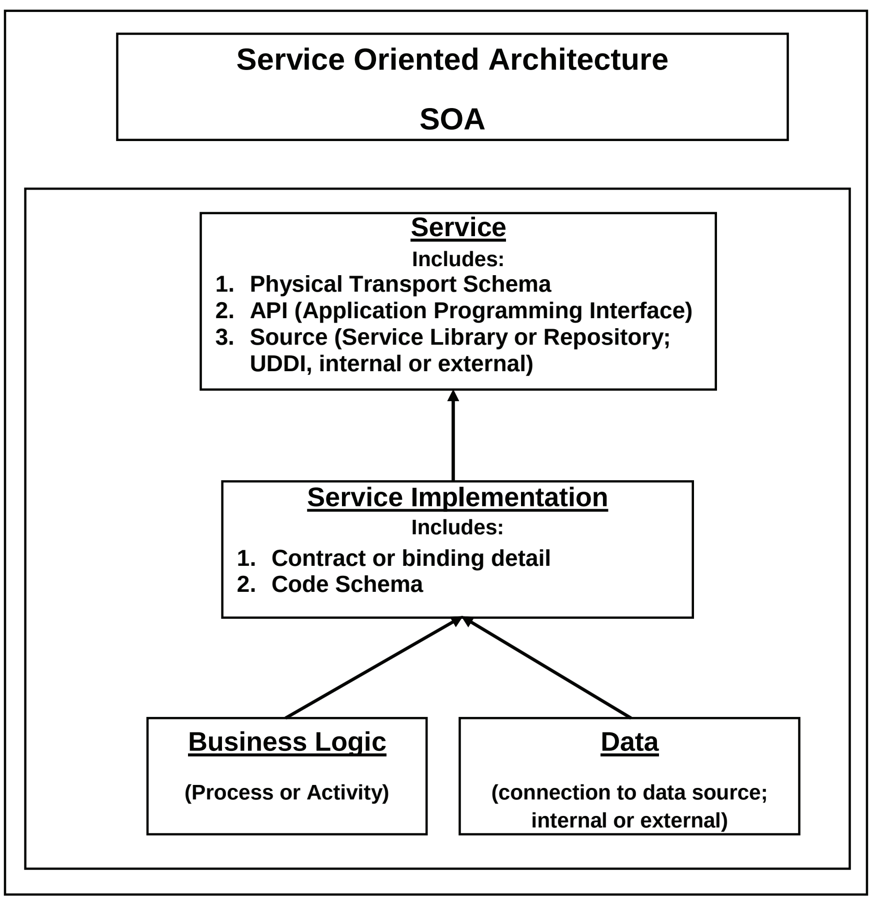
Architecture

The service component of SOA has been discussed, though admittedly at a high level. However, the architecture component has not yet been addressed and it will be helpful to speak briefly about the architecture segment of SOA. Architecture in general refers to the art (or science) behind the design and building of structures. Alternatively, an architecture may refer to a method or style of a building or a computer system. So, if SOA is taken literally as a description of its function, it could be taken to mean a structured way of organizing or arranging the services in a business or organization.

SOA FRAMEWORK

It is apparent from the existing definitions and models that service-oriented architecture is commonly seen as an architecture or way of assembling, building, or composing the information technology infrastructure of a business or organization. As such, SOA is not a technology in itself; rather, it is a way of structuring or arranging other technologies to accomplish a number of other tasks. This naturally leads to the problem of a multiplicity of definitions of SOA since many relatively similar structural arrangements of services are possible. Many of the definitions also indicate that the arrangement and relationships between modules should be loosely coupled rather than tightly coupled. This allows for customization of services based on need, and on-demand rather than some predetermined structure, but the downside is that it also leads toward a plethora of definitions and approaches to SOA implementation.

Figure 1. SOA framework



Some of the common features that seem sensible to include in a formal definition of SOA would relate to a common framework, such as that specified by Krafzig et al. (2005) or one of the other standards bodies. In other words, a framework would include metadata describing the various important features of SOA, how those features can be arranged, and the libraries or location of services that allow adopting organizations to arrange bindings or contracts between themselves and the service provider, independent of whether the service provider is internal or external. We propose the framework depicted in Figure 1 as a starting point for visualizing SOA.

Several of the standards bodies have taken a stance in creating or calling for a metamodel, at least in some form. Among them are the Open Group, OASIS, OMG, W3C, and to a lesser extent industry-related bodies such as Javaworld.com, XML.com, IBM, and Oracle.

UDDI has become a very well-known structured repository for services and service components, which speaks to the universality of the library or centralized database of services. However, more standardization efforts will be necessary to enhance the interoperability of UDDI.

It also appears, especially with the industry definitions of SOA, that the contracts, bindings, interfaces, service buses, and other implementation-related portions of SOA are important elements to be considered when attempting to give an overall definition of SOA. This unfortunately could easily represent a stumbling block in garnering consensus on a definition of SOA since each of these companies has invested significant time, human, and other likely resources toward development of their specific pieces of the SOA pie. Each company has invested heavily and thus will likely be less willing to risk that investment and any potential return and customer lock-in in order to simply agree on standards. We observed a similar occurrence of this type of behavior in the recently ended format war in the high-definition DVD market. Similarly, if the standards bodies have political or industry leanings, agreement on a common SOA definition and standards could be difficult to achieve.

Another more recent development comes from Shah and Kalin (2007). They proposed that organizations adopting SOA follow a specific path based on an analysis of business challenges, including SOA business drivers and IT barriers. This led them to speculate that a specific adoption model be used to guide the SOA implementation process. They indicated that an ad hoc SOA model is better where the benefits of new services are specific to each individual service, where the technologies may be inconsistently applied (different implementations for the same service in different projects), where services cannot be reused, and where the increases in technological complexity translate into decreased system response times. Shah and Kalin ended with a call for a strategy- or program-based SOA adoption model that is situational.

We propose that a common definition of SOA is possible and necessary, and call for negotiations among interested bodies with the aim of reaching a common definition of SOA. We realize that in practice it might prove difficult or even nearly impossible to expect such a consensus to be arrived at, but a common definition and structure of SOA would go a long way toward dealing with some of the confusion, misinformation, and hype regarding the entire subject. Difficult though it might be to expect this, a realization that SOAP, CORBA, RPC, and XML among many other technological tools have reached a point of relative agreement amongst users if not ubiquity, at least related to their underlying standards, should provide some evidence that agreements can be reached. Next, we will examine SOA from the research perspective.

POSSIBILITIES FOR RESEARCH

Research into SOA is extremely limited at this point in time. What studies exist can be classified into several distinct categories. The first includes exploratory or recommendation-type efforts that propose various means to approach SOA implementation. These investigations may or may not include proprietary industry software, but most of these research efforts propose the use of patterns or blueprints and a metamodel of SOA as a means to understanding the SOA perspective. Second, in this category are research proposals that examine company-specific technologies or tools (i.e., IBM proposing the use of Rational Software, including the Rational Unified Process) in relation to SOA design and implementation. Neither of the first two types of SOA research generally involve ideas on how to measure SOA in terms of success or failure, or even suggest metrics. Finally, the third type of research articles focus on empirical research.

SOA Development or Deployment Patterns and Blueprints, and the Meta-Approach

Stal (2006) took a roughly similar approach to what we are attempting to do in this article; he advocated using architectural patterns and blueprints (software engineering patterns) as a means to enable or foster efficient deployment of SOA. He supported loose coupling of services in a registry or library to the extent that he thought that removing the services' dependency on the registry's or provider's distinct location would benefit the deployment of SOA. Stal maintained that this would eliminate, or at least minimize, a layer in the SOA framework. He also proposed a more tightly defined and controlled integration of middleware using XML or similar tools. Basically, Stal suggested a metamodel and pattern approach to defining SOA, but did not suggest what the research might accomplish or how the research into SOA would be framed. Kim and Lim (2007) also proposed a distinct means to implementing SOA, using in this instance, business process management, in addition to a variant of the SOA framework specifically dealing with the telecommunications industry. Similar to Stal, Kim and Lim did not propose empirical research into SOA, but rather focused on implementation and standards in a specific industry.

Shan and Hua (2006) proposed an SOA approach for the Internet banking industry. They also compiled a list of patterns that have been proven successful for other online service industries. However, the models they used and ended up with are very detailed regarding how SOA should be implemented for first online companies in general, and then Internet banking specifically. This again does not propose or frame specific research but rather suggests an implementation approach and a structure for SOA.

The ESB is explained in detail, but from a general perspective rather than a company-specific approach in Schmidt, Hutchison, Lambros, and Phippen's (2005) expository. The article is informative regarding ESB implementation and design patterns, but it is not research oriented.

Crawford, Bate, Cherbakov, Holley, and Tsocanos (2005) proposed a different way to structure SOA, what they called on-demand SOA. They essentially proposed an even looser coupling of services and their connecting elements than in other perspectives of SOA. They argued that this would allow much more flexibility to the adopting organizations and the end users.

Company-Specific and Commercial Tool-Based SOA Deployment

Brown, Delbaere, Eeles, Johnston, and Weaver (2005) presented an industry-oriented perspective on the SOA puzzle. They suggested an approach to service orientation using the proprietary IBM Rational platform. Their recommendations follow similar paths as some previous research, but are also filtered through the IBM Rational lens. The article is primarily illustrative in nature, suggesting how to best implement SOA using IBM Rational tools. In a similar vein, Ferguson and Stockton (2005) also detailed IBM's programming model and product architecture.

De Pauw, Lei, Pring, and Villard (2005) described the benefits of Web Services Navigator, a proprietary tool created to provide a better visualization of SOA and Web services in a loosely coupled architecture. The tool can help with design-pattern, business-logic, and business-process analysis, and thus help with SOA architecture design and implementation.

Jones (2005) suggested that SOA, service, and Web service standards were "on the way" and provided a list of existing tools, such as UML (Unified Modeling Language) and/or the rational unified process that could aid the SOA (or service) design process. However, he also advocated the push toward formal definitions of such SOA basics as services, to the end of providing a more coherent and cohesive structure that he thought would enhance the ability of developers and adopters to understand and deploy SOA.

Research-Based Perspectives on SOA

Chen, Zhou, and Zhang (2006) proposed an ontologically based perspective on SOA, Web services, and knowledge management. They attempted, with some success, to integrate two separate research streams into one. They presented a solution to show that semantic- and syntactic-based knowledge representations could both be depicted with a comprehensive ontology that also described Web service composition. While their framework represents a step toward automated (Web) service composition, more research is still needed.

Borkar, Carey, Mangtani, McKinney, Pate, and Thatte (2006) suggested a way of handling XML-based data in an SOA or service environment. Their idea involved the use of data both able to be queried and unable to be queried, and would necessarily also involve XML-formatted data. This represents empirical research into a part of SOA, namely, the underlying services, and is at least a step in the right direction, although it does not enter the realm of research into the efficacy or ROI of SOA.

Duke, Davies, and Richardson (2005) recommended and provided details on using the Semantic Web to organize an organization's approach to SOA and Web service orientation. They suggested that combining the Semantic Web and SOA into what they called Semantic SOA would provide benefits to adopting organizations. Then they further proposed an ontological model of the Semantic SOA, attempting essentially to create a meta-metamodel of SOA using their experience with the telecommunications industry as a case example. This is one of the few high-level articles that can also be seen as empirical research.

Zhang (2004) explored the connection between Web services and business process management, and described the modular nature of the service (and Web service) perspective. He detailed the software industry's approach to Web services and provided evidence that standards development would quickly mature, beginning in 2005. He maintained that once standards were agreed upon, a connection to business process management would be easier to sell to businesses. Zhang also developed a prototype e-procurement system that composed external services to operate.

Malloy, Kraft, Hallstrom, and Voas (2006) developed an extension to WSDL. They insisted that Web services' specifications were "typically informal and not well-defined," and proposed what they called an intermediate step between requiring more formal and rigorous service specifications and the informal nature of the existing service specifications. They accomplished this balance by extending WSDL to include support for application arguments that would help automate and expand the ability of services to operate in multiple environments. They provided an example of how their WSDL extension could allow a single service to function successfully in different applications using multiple zip code formats (five vs. nine digits, and hyphens vs. no hyphens).

Verheecke, Vanderperren, and Jonckers (2006) proposed and developed a middleware level that they called the Web services management layer (WSML). They saw the primary advantage of their approach in that it provided a reusable framework. They further believed that the use of their framework would enable "dynamic integration, selection, composition, and client-side management of Web Services in client applications" (p. 49). They were aware that their approach could cause some problems in a distributed system since implementation of it resulted in a centralized architecture.

Hutchinson, Henzel, and Thwaits (2006) described a case in which an SOA-based system was deployed for a library extension collaboration project. Much of the case details the SOA approach itself, and explains the experiences of the project developers and implementers. They noted that while the SOA architecture could be expected to reduce the operational maintenance costs overall, the way the system was specified and delivered in this particular case might require more work from IT to keep some services, such as flash players, up to date. While the authors did not specifically mention it in the article, perhaps a more loosely coupled architecture might alleviate some of those operational maintenance costs.

Li, Huang, Yen, and Cheng (2007) proposed a methodology to migrate the functionality of legacy systems to a Web services or SOA architecture. They used a case study to investigate the efficacy of their proposed methodology, finding that while it was possible to make such a migration from legacy systems to SOA (or Web services), the changes that it required from the organization were considerable, and some process reengineering would likely be necessary.

MEASURING SOA AND SOC SUCCESS

Another tricky issue in SOA and SOC implementation is the measurement or evaluation of success. Traditionally, software (or system) successes and failures have been estimated by the usual suspects: traditional measures such as ROI, net present value (NPV), breakeven, internal rate of return (IRR), or other similar financially based approaches. Similarly, software itself has usually been measured in terms of errors or productivity via numeric methodologies such as lines of code, COCOMO (constructive cost model), and similar estimation techniques. These approaches are all based firmly on the idea that if we can assign some number to a system, then we can compare them across projects, systems, or organizations. The problem is analogous to the question often asked regarding enterprise resource planning (ERP) systems: If all of the Fortune 100 companies implement the same piece of software, such as SAP, then what allows one organization to differentiate itself from another if they have standardized on SAP's best processes and best practices? One way to answer that question is to examine other measures of success such as competitive advantages (Siau, 2003), competitive necessity, flexibility, agility (Erickson, Lyytinen, & Siau, 2005), nimbleness, responsiveness, and other relevant intangibles. We would even propose that the best way to evaluate SOA or SOC implementation is not ROI. Intangible but critical factors such as competitive necessity, agility, on-demand abilities, and responsiveness should be the decisive factors.

Nah, Islam, and Tan (2007) proposed a framework and critical success factors for estimating the success of ERP implementations. They empirically assessed a variety of implementation success factors including top-management support, project team competence, and interdepartmental cooperation, among many others. While the study answered a number of important questions regarding ERP implementations, the issue of assessing intangibles in terms of success factors remains a problem, not only for ERP-type implementations but also for other system types as well, especially for SOA since the SOA approach can be seen as an alternative in many ways to ERP.

Langdon (2007) noted that while many economic-based studies indicate that IT projects add value at the macrolevel, little has been done to assess how value is added at the more micro or individual project level. Specifically, Langdon proposed and evaluated a research model that included (IS) integration and flexibility as capabilities that could lead to IT business value. Of course, flexibility and integration are only two components of a larger IT capabilities structure, but the study indicates that the first steps have been taken to study intangibles in the context of an IT systems development project.

Two intangibles in the IT success-factor context are the oft-cited agility or nimbleness of a company or organization. An entire genre of systems development has emerged based on the principle of agility. However, there is little empirical evidence supporting the value added from such development approaches (Erickson et al., 2005). Since a growing number of SOA installations are constructed as ad hoc, which is in a basic sense agile, we propose that in environments where agility and nimbleness are important, so in turn are SOA and SOC important.

CONCLUSION

From the literature, it appears that only a few efforts can be said to be empirical research. A majority of the research efforts involved created tools or language extensions that would increase the interoperability of services, while other research proposed standards modifications. Many of the remaining articles published proposed new tools or the use of existing proprietary tools, described an approach to SOA from specific perspectives, or proposed model or metamodel changes. A limited number of case studies detailing SOA, Web services, or service deployments or implementation efforts provide experience reports on how best to implement such systems.

As far as we can determine, virtually no research has been formally done regarding the benefits and drawbacks of SOA or Web services. Two problems with this are likely to revolve around the nebulous nature of SOA and Web services in terms of the widely varying definition and the emerging standards issue. An effort to identify SOA and Web services metrics would help to get research into this area started.

Another area of interest involving SOA and Web services adoption is the cultural and structural impacts on the organization or business. A number of articles note the importance of those elements, but little has been accomplished in terms of research specifically connecting SOA or Web services with cultural and structural changes in organizations.

A variety of standards bodies are working separately toward formal definitions including metamodels, and a number of SOA vendors, among them some of the very large and established software industry players, have emerged. While the effort toward standardization is direly needed and commendable, a more collaborative approach would, in our opinion, benefit the industry and implementing companies and organizations as well. The seeming result of the rather haphazard approach to SOA appears to indicate that an increasing number of implementing organizations are finding it difficult to assess the cost benefit of the entire services approach. Research efforts at this point appear to be in a similar state of disarray. Until a more coherent picture of SOA emerges, its image is likely to remain slightly out of focus, and research in the area is likely to remain somewhat unfocused as a result.

Chapter 6.8
Diffusion and Oscillation of Telecommunications Services: The Case of Web 2.0 Platforms

Tobias Kollmann
University of Duisburg-Essen, Campus Essen, Germany

Christoph Stöckmann
University of Duisburg-Essen, Campus Essen, Germany

Carsten Schröer
University of Duisburg-Essen, Campus Essen, Germany

ABSTRACT

The diffusion of a Web 2.0 product or services is, unlike to traditional consumer or industrial goods, not only based on purchase. Full acceptance of Web 2.0 platforms occurs by recurring utilization. The chapter focuses on diffusion characteristics of this innovative category of ICT products and provides management concepts for competition. The concept of critical mass is applied to different growth scenarios. Additional success factors are discussed. Particularly the permanent supervision of a platform regarding its compliance with qualitative, as well as ethical and legal standards is of great importance. Adjustments to external market conditions, proactive management, and a bilateral marketing approach are a key to lasting success within the Net Economy. Markets are never settled, due to the ever changing and oscillating conditions. The chapter shows that there is always a chance to capture a market or at least to grow against competition in a Web 2.0 setting.

DOI: 10.4018/978-1-60566-194-0.ch036

CRITICAL MASS AS A SUCCESS FACTOR

The extension of electronic networks and the use of information and telecommunication technologies for the digitalization of value creation lead to a new economic dimension (Lumpkin & Dess, 2004). This newly established level of value creation, the so-called **Net Economy**, provides room for innovative business models and successful start-up firms (Kollmann, 2006). An increasing number of companies participate in the economic potential of the internet which leads to a rising level of competition. Competing players either win a market and participate in a stable and sustainable business development or fail with their idea within a short period of time (Shapiro & Varian, 1999). The roots of this phenomenon are derived from an economies of scale effect that keeps aggravating itself instead of declining. Every new user of an offered **platform** (community or marketplace) helps to raise the value of a network and makes it even more attractive for further participants. A higher number of communication and transaction activities are the possible outcome. A rising quantity of community members also increases the perceived attractiveness (site stickiness) of a platform. This can be illustrated by the following two examples: A rising number of members subscribing to an ***E-Community*** (Kollmann, 2006) raises the chance to meet likeminded individuals or to receive answers to posted questions. Also a rising number of users to an ***E-Marketplace*** (Kollmann, 2006) rises the probability to find interested customers for offered products of a supplier.

According to the presented scenarios, a special focus has to be put on the **critical mass** phenomenon, because the subjectively perceived attractiveness of a system (e.g. community) is highly correlated with the already registered number of users. A certain number of users within a network are necessary to create value among the participants at a sophisticated level. Reaching this level is essential for a network, because the enrolled participants will be reinforced to use the system on an ongoing basis, and it will become easier to convince new users to join in (Kollmann, 1998). The minimum number of participants to maintain a sufficient utility on a long-term basis is referred to as the **critical mass** (Weiber, 1992).

Especially in a **Net Economy** setting young companies experience a very competitive environment to reach the **critical mass** (Kollmann, 1998). Oftentimes, the winners of this race drive smaller competitors or copycats off the market. This conception reinforces itself in a **Web 2.0** setting (O'Reilly, 2005), where customers or members leave the status of pure information consumers. Their status changes to an active information provider and editor role (O'Reilly, 2005). Therefore, growth at a fast pace in regards to the number of users becomes the critical success factor to leave the zone of competition as a winner. Actually, the winner of this battle is able to establish a close too monopolistic market position (Shapiro & Varian, 1999). The attractiveness for new users to join a network is even higher, if *everyone else* already joined in.

Following the stated assumptions Web 2.0 **critical mass** winners are destined for lasting company performance and profits. But the real life teaches another lesson. Apparently successful market leaders are frequently challenged by various inconveniences with the potential to jeopardize their market position. In accordance with the theoretical model ***eBay™*** for example, market leader for internet auctions, announced a growing number of membership accounts alongside with rising revenues and profits (eBay™, 2006). The unmentioned downside of this success story was a flood of insolvencies among professional ***eBay™*** dealers. *The International E-Business Association* (IEBA), an association for *power sellers*, sees the roots for many discontinued businesses closely connected with an increasing number of sellers and a resulting higher level of competition. Both factors lower profits and force sellers to predatory pricing strategies. In this context insolvency reasons for most of the dealers are not on an individual, entrepreneurial level. They are based on the market characteristics of electronic marketplaces, and a substantial number of insolvencies by professional dealers of a platform will sooner or later hit the marketplace vendors.

Other **critical mass** winners within the **Web 2.0** environment like the online community ***MySpace™*** or the video **platform** ***YouTube™*** are not only the centre of interest because of their enormous growth rates and success stories. Critical notes about security issues, copyright violations, or identity theft and fraud affairs are also on the spot of public interest. Web 2.0 companies might face severe challenges, if the offered content on their platforms violates ethical or legal standards. Insufficient qualities of the offered content, as well as a mismatch between information supply and demand in the case of ***eBay™***, gain the potential for adverse effects for a market position.

Therefore, the proposed chapter aims to show how quantitative, qualitative, as well as ethical and legal matters correspond with the market success of Web 2.0 platforms. In addition implications for the competition of platforms and the concept of **critical mass** as a foundation for success in the **Net Economy** will be discussed.

WEB 2.0 PLATFORMS IN THE NET ECONOMY

In the past the internet used to be recognized as a technology to publish and distribute data, information and media content. This view was based on split-up roles: Private and commercial publishers of web content with an active role on the one hand, and passive consumers on the other hand. This *golden rule* changed in 2005, when **Web 2.0** saw the light of day. A new category of website concepts was born. The established differentiation between active content providers and passive consumers diluted. Now users were able to generate and affect contents. User generated content became the slogan for the new internet. The active role of users built the basis for innovative business ideas, which were unthinkable some months ago. Many **Web 2.0** business models, like the online community ***MySpace™*** or the video **platform** ***YouTube™***, are centered around community structures. According to Kollmann (2006) an **E-Community** facilitates contact and interaction between individuals or institutions via a digital network. Therefore, the integration of innovative ICT supports data- and knowledge transfer. These two features characterize the core activity for most of the **Web 2.0** business models. Besides arranging and exchanging contacts and information, bringing together supply and demand for economic transactions, e.g. on an **E-Marketplace** (Kollmann, 2006), is an integral feature of numerous platforms.

The common goal of **Web 2.0** platforms is to win suppliers and consumers of information for their business model in order to match them (Kollmann, 2006). Users of a **Web 2.0** platform act alternating and parallel as information suppliers and consumers. Both activities have to be considered separately, because supplying and requesting information differ in regards to motivation and acceptance. This leads to a tripolar structure. The platform operator provides a matching service to perform an exchange of information or a business transaction at lower transaction costs (Lee & Clark, 1996). The value of a **platform** not only depends on the operators' service capability and willingness to perform, but also on the contributions of the suppliers and consumers of information (derivative capability aspect). Platforms depend on queries. A higher number of queries provide a broader scope for matching activities (Kollmann, 2001). Consequently a **Web 2.0** platform is solely dependent on the participation willingness (acceptance) of its users. Therefore business development efforts concentrate on the so-called matching as a target parameter (Kollmann, 2000, 2005).

When starting a **platform**, operators have to get awareness for their services. They are challenged by the question, which points are of interest to turn internet surfers into members or subscribers for a community, or respectively customers for a marketplace. This goal can only be reached by offering a matching **platform** that delivers an acceptable service. Therefore the scientific construct of acceptance obtained growing relevance in the marketing of ICT products and services over time (Kollmann, 2001). The reason for this is that ICT technologies and applications (e.g. interactive TV, internet, cellular phones) need a specific pattern of utilization. The pure purchase is not an indicator for further activities of a user and therefore not a sufficient indicator for the economic success of a **platform** operator. Augmenting this idea, a full acceptance of a **Web 2.0 platform** is closely linked to three conditions.

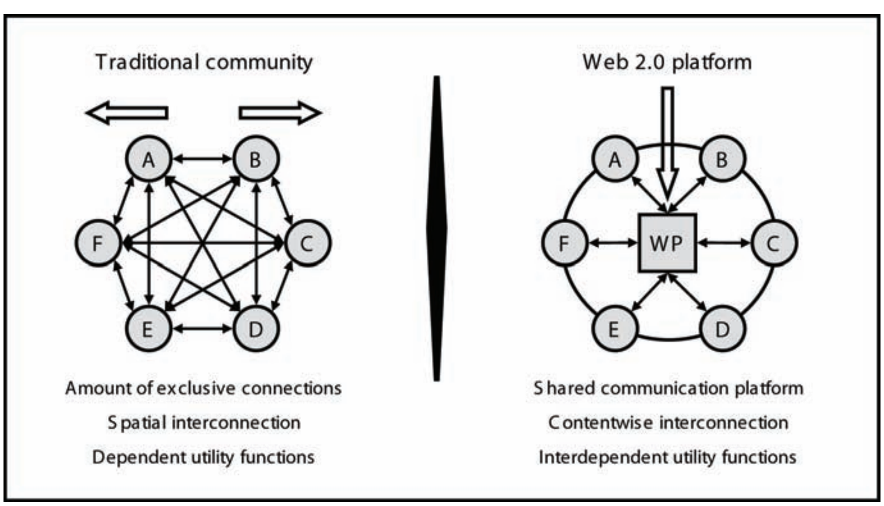
1. Connecting (Access to the platform): The customers have to get access to a platform via a security code (e.g. log-in) or provided access software. A first time registration process reflects the purchase.
2. Acting (Demand and contribution of information): The customers have to use the services of the electronic platform. Information has to be requested and provided. This opens up the potential for matching.
3. Interacting (Clearing and matching): The customers have to interact on the platform; otherwise a matching of requested and provided information cannot be executed.

Coordination of the participants is proceeded over the electronic **platform** (n information suppliers, m information consumers, and the platform operator without time and local limitations, see figure 1). Information and data between two or more counterparts is solely shared on the **platform**. The active placement and intervention into the matching process leads to a new responsibility for the platform operator, because the result of each matching affects all participants.

The attractiveness of traditional communities and marketplaces is primarily determined by the numbers of participants as a quantitative measure for their availability (see figure 1). The center of those system architectures is the exclusive connection between two counterparts (e.g. trade show or farmers market). The interaction between A and B usually has no direct qualitative effect for the utility of C. Technological external effects are conceivable under certain conditions, e.g. if all participants benefit from a network effect associated with the extension of a telephone network. However, this interpretation of a quantitative point of view is insufficient to explain attractiveness of progressive internet platforms.

In a **Web 2.0** system the interconnection of participants does not consist of exclusive one-on-one data links. An **E-Community** or **E-Marketplace** as a commonly shared platform represents the center of the system architecture (see figure 1). Information of a database is available for every user on the network. Options to alter, comment, or expand the provided content are inherent to the

Figure 1. Illustration of traditional communities and Web 2.0 platforms



system. A transparent provision of information leads to direct effects on the qualitative utility function of C (economies of scope), if A and B exchange information. An agreeing or derogative comment of B to a contribution from A, may lead to a valuation of C regarding the statement. Further, as Pavlou and Gefen (2005) state, a psychological contract violation with an individual seller is proposed to prompt a generalized perception of contract violation with the entire community of sellers in a marketplace. Internet auctions for a specific item are open to several participants. The bid of A has a direct impact on the utility function of all other bidders. The following paragraph will deal with the resulting implications for the diffusion of Web 2.0 platforms.

THE DIFFUSION OF WEB 2.0 PLATFORMS

Research on **diffusion** provides answers to the question how an innovation will spread on a market (Rogers, 2003, Pavlou & Fygenson, 2006). Services of a **Web 2.0** platform, which are offered as a commercial product, could be part of a study on diffusion, too. Research in this field is based on the presumption of a recurring use (acceptance) of a product or service, not on a one-time purchase (adoption). In regards to the diffusion of **Web 2.0** platforms the following three questions are of interest.

1. Which factors have an impact on the diffusion of a Web 2.0 platform on a market?
2. How fast does a Web 2.0 platform spread on a market?
3. What are the growth characteristics of a network?

The successful **diffusion** of a **Web 2.0 platform** is completed, if all interactions of a defined market are handled by this platform. For the evaluation of **diffusion** the aforementioned quantitative alignment of the network effect (higher number of participants = higher probability to find appropriate counterparts for interaction) appears with an economies of scope effect (nature, size and trend of an executed transaction, including its impact on the overall system). The following paragraphs will analyze the main problem areas of diffusion and oscillating degrees of utilization in the light of both effects.

Problem Areas of Diffusion

The **diffusion** of a **Web 2.0** platform is associated with quantitative, qualitative, ethical and legal challenges. Those issues will be discussed in the following.

Quantitative Problem Areas

Attractiveness of a web **platform** is significantly linked to the number of participants. A higher participation level raises the chance to reach other individuals. Every information supply (e.g. a provided video) as well as every information demand (e.g. on a personal level) need at least one counterpart to enable a platform provider to match requests. The service of the platform provider creates an indirect utility that is derived from the usage of an interactive relationship within the communication system, the so-called derivative capability aspect (Katz & Shapiro, 1985; Farrell & Saloner, 1985). The derivative utility following the usage of such a good increases with the number of participants, and the intensity of use by the other participants (Weiber, 1992). The result is a network effect. Common examples for goods with direct network effects are all types of ICT-systems. The utility of each participant is advanced with every new customer, who helps to grow the network. In connection with the bilateral customer orientation (information supply and demand) of the platform provider, specific characteristics within the **diffusion** of a **platform** can be derived for different development stages (Kollmann, 2001).

1. Chicken-and-Egg-Problem: One reason for matching problems on a **Web 2.0** platform is derived from the so-called Chicken-and-Egg-Problem (Durand, 1983; Earston, 1980). The following two examples aim to illustrate this circumstance. An insufficient number of suppliers or offers lead to an absence of customers on the platform. An insufficient number of customers or requests lead to a lack of suppliers. The dilemma situation, which counterpart (supplier or consumer) at first has to get involved with the platform, is deemed as an obstacle for the development of a business.
2. Collateral-Critical-Mass-Problem: The installed basis, i.e. the number of users already present in a platform, determines the utility of the platform for new users since a greater number of users also increases the number of potential interactions (Farrell & Saloner, 1986). The larger the installed basis, the larger is the derivative utility for the participants (Kollmann, 2001). **Web 2.0**-platform providers are confronted with a collateral **critical mass**, because of the bilateral orientation (Kollmann, 1998). Suppliers need a certain level of counterparts or requests, in order to commit to or use a marketplace. Simultaneously, a certain level of suppliers or offers has to be provided, in order to persuade a customer to facilitate a marketplace. This problem supersedes itself, if the customer base on both sides grows to a sufficient point, where the derivative utility exceeds a certain level.
3. Equilibrium problem: Bilateral matching results in a mutual state of dependence regarding the number of suppliers and consumers, and respectively their offers and requests. Consequently the platform provider has to take into consideration that offers and requests almost equate themselves. Bilateral marketing activities support this endeavor (Kollmann, 1998) and help maintaining a high matching level (one offer = one request).

Qualitative Problem Areas

Contrary to the established belief in an exclusive utilization act between supplier and consumer interaction, the critical phase of a matching includes an additional economies of scope effect associated with the quality of interaction. The decision to subscribe to and use a **platform** has to be expanded. Besides complying with quantitative issues, meeting the qualitative requirements of the suppliers and consumers with information is of equal importance. If they realize that the web platform complies with their demand and interaction needs, they are willing to utilize the platform's services. The following issues with regard to qualitative problems have to be solved (Kollmann, 2001).

1. Matching performance problem: An exclusive focus on the number of suppliers and consumers is insufficient to measure the quality of the interacting counterparts, as well as their level of satisfaction with regard to the exchange of information. The demanded level of interaction has to correspond with the expectations of the participants. The degree of satisfaction is closely linked to three core areas of need, which are information, relationships, and business (Hagel & Amstrong, 1997), as well as the related concept of the heterogeneity-dependent level of commitment. Participants look for like-minded individuals on a platform and relevant content to fulfill their information needs. New discussion threads have to be established to acquire additional members, which cover further fields of interest. Platform operators are exposed to a dilemma situation, because of the diametrical impact of the heterogeneity of discussion threads with regard to a growing member base and the persistent

commitment of current participants.

2. Reality check problem: The structural conditions of virtual platforms disallow to validate provided information with reality. Anonymous publishing options among some platforms aggravate this issue. Information and reality fall apart frequently. Some of those discrepancies occur inadvertently, e.g. if a change of address is not entered into a database or an information is provided on a non-current standard of knowledge. More frequently intentional misrepresenting takes place by sugar-coating one's profile on the web, or even worse with criminal intention. Because the roots of a reality gap are unknown to the participants, misrepresentations might reduce the commitment or ongoing patronage of a user.

Ethical and Legal Issues

The addressed willful misrepresentation is an example for the multitude of ethical and legal issues associated with user generated content, among other legal problems of internet **platform**s and their foundation. Current lawsuits on those topics will give answers to important questions and provide future guidance on duties of **Web 2.0** platform operators. Liabilities for provided content on a company's website and linked content from external sources, as well as infringements of users (e.g. announcement of a criminal offense) and related duties of care have to be clarified. The results of those decisions will inevitably have a major impact on the further diffusion and development of **Web 2.0** platforms. In the following section two problems will be discussed.

1. Freedom of expression problem: Despite the fact that every human being possesses the right to express an opinion, legal and ethical standards have to be obeyed. Sometimes those standards are violated on anonymous web-based communication platforms. Comments with an extremist, offending, or sexually harassing content cannot be tolerated by any platform operator. Other categories, like advertising and promotion activities, can be classified as unwanted too. Guidance for communication on the internet is given by the so-called *netiquette*, derived from internet and etiquette. The recommended behavior of the netiquette is not legally binding, but helps to maintain and develop a positive net culture. The voluntary agreed upon rules are frequently incorporated in codes of conduct of platform operators. A breach of the rules leads to a closing of discussion threads, cancelation of comments, or dismissal of accounts, because a negative communication culture bears the lasting potential to lower the acceptance of a platform.
2. Problems associated with the adoption of external content:

Particularly on video platforms users provide, intentionally or unintentionally, copyrighted material from other websites or real sources. By now, copyright holders mandate agencies (e.g. *copyrightcontrol*^{TM}) to retrieve their protected material. The platform operator is responsible for inflicting penalties of participants and to remove copyrighted materials. Preventing an upload of protected material is virtually impossible, because the violation of a copyright just becomes apparent after a user has posted illegal content. Even reactive behavior leaves a legal stain on the platform operator's vest, as despite the fact of a fast content removal a breach of law already happened. Since there is no appropriate method available on the market to avoid the upload of copyrighted material, all prominent platform operators strive towards general licensing agreements with bailees. Those arrangements would allow them to leave copyrighted material on their websites and protect them from costly lawsuits and negative impacts on their market penetration.

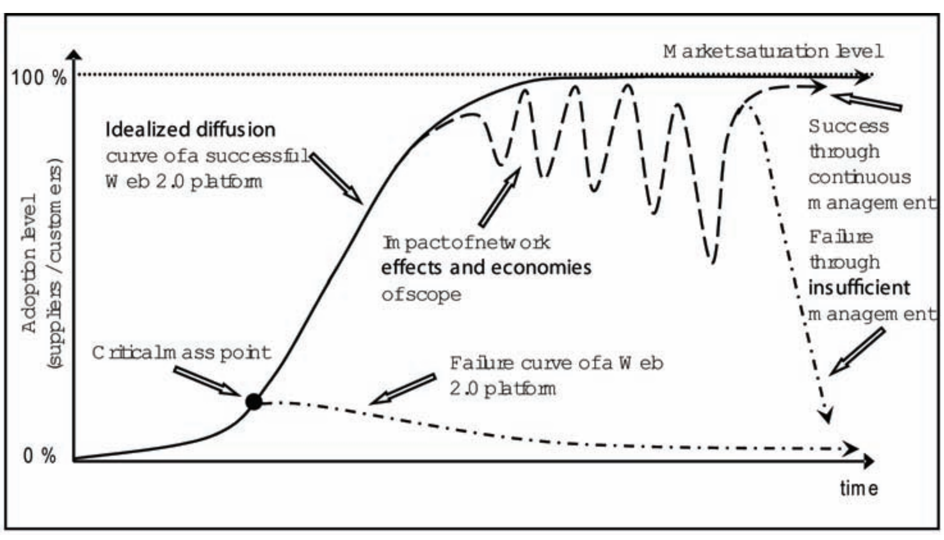
Oscillating Effects of Web 2.0 Platforms

The classical theory of **diffusion** was developed for so-called singular goods. Their diffusion proceeds with the act of buying. In a **critical mass** system the scope has to be extended by the variables of *connecting* and *acting* (see chapter *Web 2.0 Platforms in the Net Economy*) as constitutive determinates for diffusion (Weiber, 1992). With traditional consumer and producer goods the act of buying creates a positive and irreversible impact for diffusion. However, ICT service contracts bear the risk of being cancelled (e.g. mobile phone contract, website account), which limits the chance to realize demand synergies. As an extreme example reversible utility could cause a declining diffusion (see figure 2; Weiber, 1992). The characteristics of a **diffusion** curve in a **critical mass** system generally do not reflect a monotonically increasing function; in fact a considerable drop is also possible.

Diffusion Characteristics

The traditional model needs an expansion within a **Web 2.0** setting, because the connecting act is an insufficient parameter to evaluate **diffusion**. It is just a necessary requirement for adoption. The market success of a **Web 2.0 platform** depends directly on the participants' constant utilization and interaction as a reliable measure for adoption, and therefore acceptance (Kollmann, 2001). An adequate utilization and interaction discipline supports a premium quality of information and knowledge transfer among the participants of a platform with positive effects for the whole market system. Also the recurring utilization and interaction is a prerequisite to realize constant cash flows for the platform operators. Accordingly the concept of **diffusion** has to be extended beyond the purchase dependent quantitative measure of participants to the utilization and interaction dependent quantitative interaction measure. The reversibility of utilization and interaction has to be considered in this context. Due to the planning interval the sequence of the three adoption and acceptance acts is interpreted as a discontinued multiple event. This process is characterized by permanent oscillations

Figure 2. Diffusion of Web 2.0 platforms



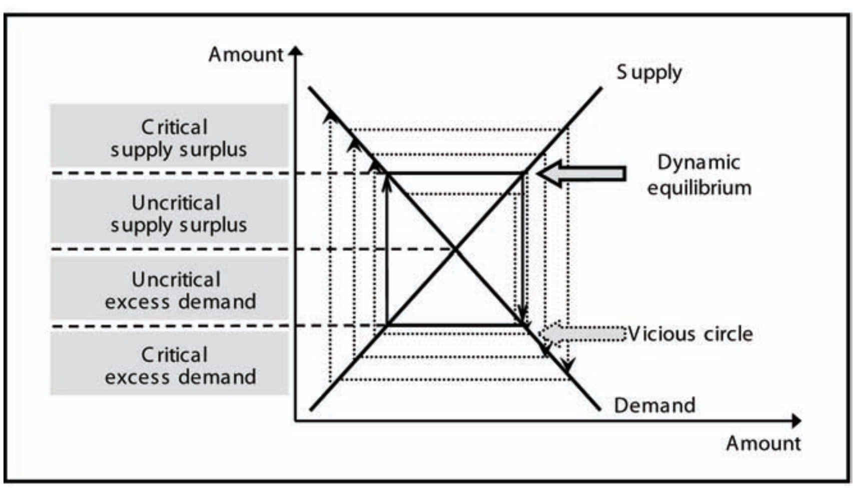
making **diffusion** a permanent companion. The reach of market saturation is not only linked with negative adoption and acceptance ratios, but also with alternating positive and negative ratios. The direct consequence is an oscillating development at market saturation level.

This effect is caused by the circumstance of negative utilization and interaction levels, which lead to a renouncing or deregistration by the participants. The original decision of adoption is withdrawn. Potential reasons to resign are caused by effects from quantitative, qualitative, ethical and legal issues. Suppliers and consumers of information feel uncomfortable about these aspects. The interconnection of participants has a negative impact on their individual utility function and the whole market system. An oscillating **diffusion** is the result (see Figure 2). In this context special attention has to be paid to the proportion of information supply and demand. As postulated, both factors should create an equilibrium to meet all matching requests and create a high level of satisfaction among the community members. The ever-changing level of participants leads to an alternating level of supply and demand. **Web 2.0 platform**s with a transaction oriented business model (e.g. ***eBay***^{TM}) use the price of goods as an instrument to regulate the proportions of supply and demand. Even though the control mechanism does not converge, due to continuously changing prices and numbers as well as suppliers and consumers, an indifferent dynamic equilibrium is the possible outcome (see figure 3).

Communication oriented platforms are faced with different challenges. A price based self-regulating mechanism does not exist in their business environment. Monitoring each market situation is important to perform intervening actions. From a platform operator's point of view the dynamic participation of suppliers and consumers is not necessarily associated with challenges. The dynamics reveal a harmful potential, if a critical supply surplus or excess demand is detected. Both scenarios cause the same effect (see figure 3).

The reduction of supply side participants will most likely lead to a decreasing information supply. Hence there is not enough potential to match all information requests. This causes a permanent loss of attractiveness on the demand side, as the offered information does not meet expectations. A lack of quantity and quality causes consumers to leave the **platform**. Likewise the lower number of requests makes it even more unattractive for suppliers to provide information. In this case the

Figure 3. Adoption process of information supply and demand



development of a platform does not induce an oscillation, but moreover a creeping and declining growth. Neither suppliers nor consumers of information are stimulated to return to the platform and utilize the services again (see figure 3).

In conclusion, the control mechanism of supply and demand generates a self-aggravating effect with a positive (virtuous circle) and negative (vicious circle) development potential (Kollmann, 1999). This control mechanism makes the management of a **Web 2.0 platform** complex, because the operator as an independent facilitator faces a bipolar user group simultaneously. Matching efforts should consider individual as well as general interaction requests to fulfil the expectation of opposed groups of interest.

The positive scenario (virtuous circle) in accordance with the **critical mass** effect leads to a continuous growth of power, achievement potential, and attractiveness of the platform. A significant gain of information suppliers typically shows an increase of requests with positive effects on the choice of the selected set of matching opportunities. In turn, the positive impact raises consumer satisfaction and the number of information requests. The flourishing demand for information lifts up the platform attractiveness for the suppliers and so forth (positive loop).

As stated before in this paragraph, changed market conditions may possibly restart a negative control mechanism. Within this vicious circle a significant loss of information suppliers leads to a clear reduction of requested information. Negative impacts on the number of choices for a matching lead to a high number of unmatched interaction demands. This has a negative impact on consumer satisfaction and consequently on the amount of information request. A declining demand reduces the attractiveness of the platform for suppliers, which leads to an ongoing downturn of supply and so forth (negative loop). The **Web 2.0** platform could suffer from those effects by a continuous loss of power and achievement potential. At the bottom line the existence of the platform might be at stake.

The oscillating characteristics of the **diffusion** curve lead to serious implications regarding the management of a **Web 2.0 platform** and the competition between web-based communication platforms in general. Those aspects along with the illustration of the **critical mass** effect as a success guarantee will be explained in the following paragraph.

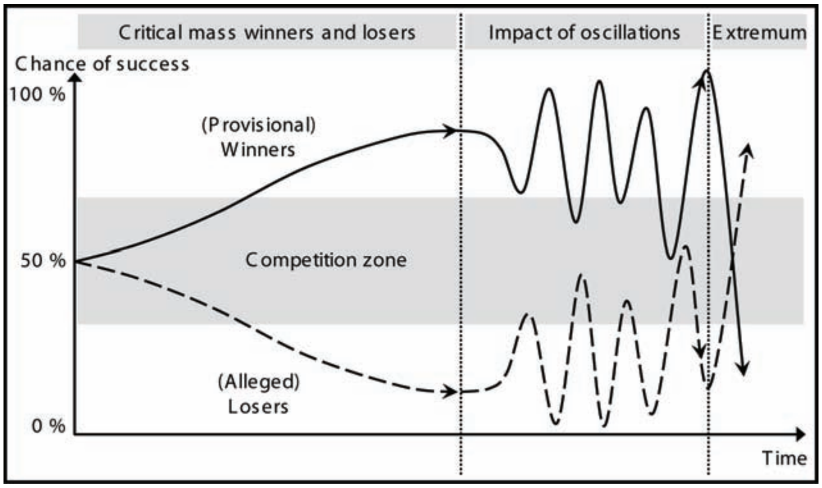
Competition on Diffusion

Competition in the **Net Economy** is characterized by an oscillating utilization of **platform**s. Therefore reaching a **critical mass** does not automatically assure a promising and stable development (see figure 4). Even on saturated or apparently settled markets threats for **critical mass** winners occur on a frequent basis. Alleged losers or innovative start-up companies occasionally create surprisingly good chances to grow against reputable competition.

As demonstrated, established **Web 2.0** platforms are endangered to lose participants. In a worst case scenario they start a vicious circle with the potential to bring their company down. The goal of successful **platform**s is therefore to maintain equilibrium between the bipolar groups as well as safeguarding compliance with qualitative, legal, and ethical standards. Lasting survival is closely connected with a high level of commitment among the participants and protection against competition. The continued management of a web **platform** becomes the critical factor of success. Provisional **critical mass** winners have to be on permanent alert, instead of relaxing in their accomplished position. Ongoing market evaluations and proactive influence on current developments on the respective network through bilateral marketing are inevitable.

Weak phases of critical mass winners provide opportunities for start-ups and established competitors to attack the supremacy of market

Figure 4. Competition in oscillating areas of conflict[1]



leaders. The existence of financial strength and survivability supports the gain of market shares (see figure 4). It is unrealistic to turn around a market completely or drive a leader in a certain field off the market, but addressing special target groups with innovative niche products receives growing popularity. Current examples are university and high school student communities, which recently started their services. Starting a positive control mechanism (positive loop) is the beginning to overcome the **critical mass** sustainably. Especially young start-ups are confronted with the challenge to reach **critical mass**. Their brand name is usually unknown to the broad public and the network attractiveness of their platform is limited. But the value of a network product is not solely based on the number of participants. Future development expectations also play an influential role (Hagel & Armstrong, 1997). Well timed and promising announcements to the market in advance (vapor marketing) and the management of expectations combined with additional online and offline marketing activities bear the potential to occupy a niche by the massive acquisition of new customers.

CONCLUSION

The **critical mass** plays a vital role for the implementation of internet business models. As described, the **critical mass** concept is of crucial importance in the age of **Web 2.0**. Current developments show further challenges besides this success factor. Those challenges have to be taken into account with the management of a **Web 2.0 platform**, because they could have a severe impact on company development. Particularly the permanent supervision of a platform regarding the compliance with qualitative, as well as ethical and legal standards is of great importance. Adjustments to external market conditions, proactive management of the platform, and a bilateral marketing approach are key for a lasting success within the **Net Economy**. Finally competitors and founders of (new) ventures should keep in mind that a market is never settled, because of the ever changing and oscillating market conditions. There is always a chance to capture a market or at least to grow against competition.

KEY TERMS AND DEFINITIONS

Critical Mass: Of users is an important success measure for Web 2.0 platforms, because the subjectively perceived attractiveness of a system (e.g. community) is highly correlated with the already registered number of users. A certain number of users within a network are necessary to create value among the participants at a sophisticated level. Reaching this level is essential for a network, because the enrolled participants will be reinforced to use the system on an ongoing basis, and it will become easier to convince new users to join in. The minimum number of participants to maintain a sufficient utility on a long-term basis is referred to as the critical mass.

E-Community: Stands for a virtual community. E-Communities are one sort of communication platform on the internet, and support or initiate business processes. They are used to build constant, self dynamic communication and interaction processes.

E-Marketplaces: Are virtual-based organizations to exchange services. An E-Marketplace has an institutional framework for transaction processes. They can be interpreted as virtual space where supply and demand is coordinated.

Net Economy: Refers to the commercial/business dimension of electronic data networks and is therefore a digital network economy. Different electronic platforms perform the execution of information, communication and transaction processes. The starting point for its expansion is the development of the information society. The basis of the Net Economy is formed by four technological innovations: telecommunication, information technology, media technology and entertainment (the so-called TIME markets). These innovations have, and continue to, significantly impact the possible ways in which information, communication and transactions are managed. The increased support of business processes using electronic systems takes centre stage here. There are a number of terms for this that can be identified (e.g. e-business, e-commerce, information economics, network economics), which can, to some degree, be used synonymously.

Netiquette: Is derived from the terms internet and etiquette. Despite the fact that every human being possesses the right to express an opinion on the internet, legal and ethical standards have to be obeyed. Sometimes those standards are violated, especially on anonymous web-based communication platforms. Comments with an extremist, offending, or sexually harassing content should not be tolerated by any individual or platform operator. Guidance for communication on the internet is given by the so-called netiquette. The recommended behavior of the netiquette is not legally binding, but helps to maintain and develop a positive net culture. The voluntary agreed upon rules are frequently incorporated in codes of conduct of platform operators.

Vapor Marketing: Is characterized by promising announcements to the market on products or services in advance and the management of expectations combined with additional online and offline marketing activities.

Web 2.0: Is the next evolutionary step of the internet. In the past the internet used to be recognized as a technology to publish and distribute data, information and media content. This view was based on split-up roles: Private and commercial publishers of web contents with an active role on the one hand, and passive consumers on the other hand. This golden rule changed in 2005, when Web 2.0 concepts as a new category of websites were established. The traditional differentiation between active content providers and passive consumers diluted. On Web 2.0 platforms users are able to generate and affect contents. User generated content became the slogan of Web 2.0. The active role of users built the basis for innovative business ideas, which were unthinkable before. Many Web 2.0 business models like online communities or video platforms are centered around community structures.

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of Web technologies, which include issues related to usage, as well as failures and successes in Web implementation. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters address privacy concerns in Web logging, Web information extraction, and Web rules. Overall, contributions within this section ask unique, often theoretical questions related to the study of Web technologies and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1
Applying an Organizational Uncertainty Principle:
Semantic Web–Based Metrics

ABSTRACT

The theory of bistable perceptions in the interaction indicates the existence of an uncertainty principle with effects amplified at the organizational level. Traditional theory of the interaction, organizational theory, and the justification for an organizational uncertainty principle are reviewed. The organizational uncertainty principle predicts counterintuitive effects that can be exploited with the Semantic Web to formulate a set of metrics for organizational performance. As a preliminary test of the principle, metrics derived from it are applied to two case studies, both works in progress, with the first as an ongoing large system-wide application of web-based metrics for organizational performance and the second as a case study of a small college where web-based metrics are being considered and constructed. In preparation for the possibility of machine-based real-time metrics afforded by the Semantic Web, the results demonstrate a successful theory and application in the field of an uncertainty principle for organizations.

INTRODUCTION

Overview. No theory of organizations is widely accepted today (Pfeffer & Fing, 2005). In this chapter, we provide a brief discussion of the problems with traditional organizational theory and, focusing on fundamentals, a classical (quantum) alternative model that accounts for predictions from traditional theory and at the same time its supposedly spurious but ultimately disconfirming findings. With its focus on the individual, traditional theory, also known as methodological individualism, encompasses social learning theory (SLT) and game theory. SLT includes classical or Pavlovian conditioning, operant or Skinnerian reinforcement, and modeling (for a revised version and summary, see Bandura, 1989). In contrast to SLT, game theory focuses on the interaction between two or more individuals (Von Neuman & Morgenstern, 1953), but like SLT, it is static; an attempt to make game theory dynamic employs repeated presentations of static game matrices. But the need for the classical (quantum) alternative is inherently based on the fundamental questions raised by the traditional focus on the individual.

In addition to theory, we review field data and the application of the organizational uncertainty principle in the form of performance metrics to two case studies, one of an ongoing, long-term nature and the other incipient. Both case studies are web-based. We include a review of the future semantic web and its implications for the two case studies. Finally, we discuss future prospects with the semantic web for theory, tests and computational models of the organizational uncertainty principle, and a path forward for the two case studies.

From the perspective of the Semantic web, our objectives are to review traditional social learning and game theory for organizations and the alternative organizational uncertainty principle. Our objective for the organizational uncertainty principle is to justify its formulation based on evidence and to review two case studies that use metrics to exploit the organizational uncertainty principle. Our final objective is to provide a path forward with automatic machine-based data generating real-time online metrics for future research with the semantic web.

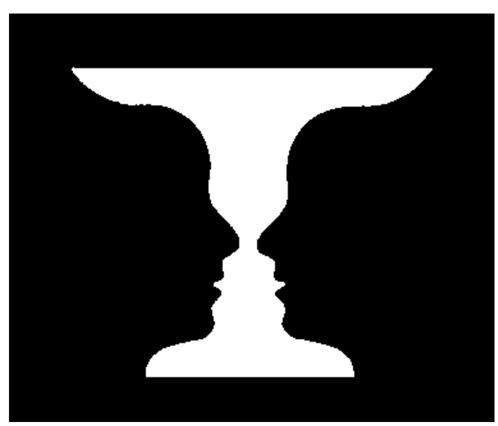
BACKGROUND

Definitions

In the Background, we define bistability, the organizational uncertainty principle, SLT, game theory, organizational theory, and Semantic web. In addition, after each term is defined, we provide a brief literature review for each term. At the end of the references, we summarize these key terms.

Bistability. Bistability is best explained with an example of an illusion (see Figure 1). It occurs when one data set can produce two mutually exclusive interpretations. While the entire data set is processed cognitively by an individual, both interpretations of a bistable illusion cannot be held in awareness simultaneously (Cacioppo et al., 1996). According to Bohr (1955), multiple interpretations support the existence of different cultures. Further, given the importance of feed-

Figure 1. An example of bistability



In this very simple two-faces vase illusion, an observer is incapable of observing both aspects of this single picture at the same time.

back to social dynamics (Lawless et al., 2007), the possibility of rapid shifts ($j\omega$, where j is the imaginary number $\sqrt{-1}$ and ω is the discrete frequency in radians per second) between each bistable interpretation increases uncertainty in the non-observed interpretation which not only can create social problems between different groups, but also support the existence of an uncertainty principle, characterized as tradeoffs between incommensurable views (e.g., the rapid shifts in the interpretations presented to a neutral jury during the cross-fires of courtroom debates). We propose that measurements of bistable phenomena collapse interdependence, decreasing uncertainty in observed aspects of a bistable phenomenon while increasing uncertainty in non-observed aspects; e.g., questionnaires of interdependent cognitive-behavior states.

Organizational uncertainty principle. The organizational uncertainty principle acts as a tradeoff in attention directed at reducing the uncertainty in one factor, such as a worldview or business model, with the result that the uncertainty in a second, interdependent factor is inversely increased, such as the execution of a business model. It is based on Bohr's (1955) famous notion that the quantum uncertainty principle applied to social situations is captured by the bistability of action and observation. That is, the more focused a collective of individuals are on acting out a series of steps, the less observant they become of their actions. Applied to societies, clusters of action-observation uncertainty couples form a causal path for different cultures based on multiple interpretations of the same business model or worldview (e.g., religion, liberalism, conservatism). The organizational uncertainty principle we have proposed links uncertainty between planning and execution as well as between resource availability and duration for plan execution (Lawless et al., 2006).

Social learning theory. SLT is a term coined by Bandura (1977) to include the three different schools of thoughts that accounted for learning by organisms, but particularly apt for humans. These three schools were classical conditioning (associations), operant conditioning (rewards and punishments), and modeling, Bandura's own school of thought. According to Bandura, modeling subsumed the other schools of learning. SLT works well in changing behavior at the individual level, irrespective of an individual's cognitive contributions or willingness to change. However, it offers little in the way of insight into organizational dynamics or organizational change, such as mergers and acquisitions (M&A), restructuring, or solving ill-posed cultural problems. More relevant to our thesis, SLT has been adapted to cognitive behaviors, which are dependent on surveys of interdependent physical behaviors. The critical assumption usually made for SLT is that self-reports of the cognitive perceptions of behavior match the behaviors that actually occur, an assumption not supported empirically.

Game theory. Game theory was invented in the 1940's by Von Neuman & Morgenstern (1953). It is a one-shot game, or a series of repeated games, played by two or more agents. In its most basic form, the game configuration presents two static, arbitrary choices for payoffs to each player. Payoffs are interdependent. For example, in the well-known and well-studied Prisoner's Dilemma Game, two players (prisoners) who cannot communicate to each other must decide whether to cooperate with each other, thereby gaining the most points for their dyad, or to compete against each other, producing the least total points for their dyad (Nash equilibrium). However, the best individual payoff occurs if one player competes under the condition that the other player cooperates. Although no communication occurs between the two "prisoners" undergoing simulated interrogation "by the police" in two isolated rooms, the feedback afforded by repeated games from observing prior partner choices affects future choices, leading to Axelrod's (1984) "evolution" of cooperation.

One of the problems with game theory is that it is normative (Körding, 2007). The results from playing these games follow the prevailing social norms independently of fundamental human behavior. That is, the value of the choices available to be made by the participants are not based on empirical support on improving social welfare, but on society's worldview of the ideal social behavior that promotes social welfare; viz., cooperation is superior to competition (this arbitrary choice by scientists is analogous to choosing market winners by authoritarian or command decision-making governments). Second, game theory inverts the assumption made by SLT about behavior. Game theory assumes that a static configuration imposed on cognition generates the desired (normative) behavior exactly. As a consequence, although providing very clear predictions, the results from games do not predict human behavior (Sanfey, 2007).

In sum, when considering the two prevailing models in the social sciences, game theory and social learning theory, these two models of methodological individualism do not focus on improving social welfare, generating creativity, or solving social problems; however, they expect to derive these benefits secondarily. Further, both theories assume the existence of a 1:1 mapping between interdependent states of cognition and behavior, leaving no room for the collapse of interdependence; e.g., by measurements or decision-making. This situation places social scientists in a box—they recognize that restrictions for self-reports are necessary in at least the case where extreme claims made about behavior cannot equal actual behavior (for hypochondria and alcoholic denial, one over states self-reported behavior and the other under states self-reported behavior).

Organizations. Organizations are social groups that perform a function which often cannot be done by an individual alone. Organizations do this by assigning interdependent roles to a set of independent individuals, which requires information coordination and blocking to form them into a working collective, but which consequently amplifies the capabilities of an individual (Ambrose, 2001). An organization arises to serve a function when its operational costs are less than the benefits it accrues and provides to its members (Coase, 1937). It is likely constructed around a geographical centroid (x) about which its business attributes are centered, planned and modeled (i.e., BM_x; derived from Sukthankar, 2008). But multiple theories of organizations exist (Weick & Quinn, 1999). Pfeffer and Fong (2005) concluded that one of the problems is the lack of a foundational theory for organizations; consequently, they proposed the need to incorporate illusions into basic organizational theory. Although "illusions" could be metaphorical, imaginary factors are instrumental in engineering to model oscillations ($j\omega$). We propose that active illusions bruited about during an open discussion interact with real world feedback to generate discussion oscillations ($j\omega$) until interdependence collapses.

Semantic Web. The Semantic web is an ongoing project to extend the World Wide Web (WWW) to permit humans and machines to collaborate efficiently. As envisioned by Berners-Lee (2007), inventor of WWW (and web languages URI, HTTP, and HTML), the future Web should evolve into a universal exchange for data, information and knowledge. Without a universal standard for machine access, HTML data is difficult to use on a large scale. The Semantic web solves this problem with an efficient global mesh for information access by both humans and machines.

The Semantic web includes a Health Care and Life Sciences Interest Group (HCLSIG, 2008) to establish interoperable data standards for "connected knowledge" to improve collaboration across the health care and life sciences, in our case, military medical research training services. The goal for HCLSIG is to reduce medical errors, increase physician efficiency and advance patient care and satisfaction. It includes document annotation and rule processing (with XML formats, OWL ontologies and SWRL rule processors).

A future option for the Semantic web, but one we pursue now in Case Study 1, may be electronic dashboards to link scientific publications and electronic medical records to associate disease, drug compounds, biology and pathway knowledge between R&D groups. As a final concern for HCL-SIG, there is today no widely recognized machine accessible semantic differentiation between a manuscript and publication; illustration and experimental image data; or between an experiment, data, interpretations, and the hypothesis that an experiment was designed to validate. Initially, our first web-based study in Case Study 1 addresses only parts of these problems with an adaptive electronic Institutional Review Board (eIRB) for research protocols rather than medical records; but associated with the eIRB, we are considering business intelligence for individual organization and system-wide performance metrics, and linking scientific publications from multiple military R&D groups to improve patient care.

Brief Literature Review

In addition to the literature reviewed in the background, an additional but brief review is provided here to place our work in a historical context. On its face, Durkheim's (1893) "social facts" stand against Weber's (1958) methodological individualism, today ingrained in game theory, where the choices available to those playing games are influenced by the social and religious norms existing within a culture (Körding, 2007). As an example, the choice to cooperate with a partner in the Prisoner's Dilemma Game is configured with a higher value than the choice to defect from a partner, even though from an information theory perspective, society often gains significantly more social benefits from competition than cooperation (Lawless & Grayson, 2004). While social norms should not be disparaged but studied, neither should scientists favor the norm of cooperation by configuring it with a higher social welfare value, similar to an industrial policy that chooses the winners for its society. But there are limitations to Durkehim's view, too. If reality is bi-stable, social facts are open to multiple interpretations.

Parsons and Luhman contributed to cybernetics and control theory as an information approach to controlling and modeling society. Parsons (1966) developed a systems approach as a grand theory of society. He used systems as a tool to analyze the function of society, concluding the systems that adapt to their environment had evolved into more efficient systems; however, in that the environment is ever changing, adaptation is not an optimal control strategy (Conant & Ashby, 1970). Parsons influenced Luhmann's (1984) theory of autopoietic, or self-organizing, systems. Luhman believed that autopoietic systems filtered information from the environment, independently of other systems, making them autonomous, but also apart from society. Elias (1969) contributed to cybernetics with his ideas on figurational, networked or interconnected structures as the source of power over other systems. Crozier and Friedberg (1981) used game structures to explicitly analyze power and strategy between organizations and their members as interdependent actors. But the limitations remain for game theory from the influence of social norms and the lack of a theory of uncertainty.

Finally, and contrary to Weber's view of different beliefs producing structural differences in a society, Montesquieu (1949) suggested that checks and balances contribute to society by limiting power. Madison applied Montesquieu's idea by building a constitutional government based on checks and balances (Hamilton, Madison, & Jay, 1787-1788), concluding that social structure controls and stabilizes government independently of the social norms in existence. Further, not only do checks and balances recognize the limits of situational awareness, motivated by the search for meaning at the individual level (Carley, 2002); but also, consensus rules and compromise dilute the added information provided to society by checks and balances, their strength. However, compromise leads to an "action consensus" based on a concrete plan of action, compared to the unified worldview of consensus seeking, which reduces the likelihood of action (Lawless et al., 2008b). This is not to conclude that Weber's ideas missed the mark. Just the opposite. Weber understood that the tradeoffs between the incommensurable beliefs of Confucianism and Puritanism produced profound differences in the control of and social welfare benefits for two social systems, which agrees with the uncertainty relations presented below.

MAIN FOCUS OF THE CHAPTER

In general, most of social science is predicated on the assumption that observations of behavior, especially the self-observations made in response to questionnaires, provide perfect or near perfect information about a target behavior, thereby leaving no room for an uncertainty principle. However, striking problems exist with asking agents about the causes of their behavior (self-reports, surveys, structured interviews, case studies). Baumeister et al. (2005) found that a 30-year meta-analysis of survey data on self-esteem correlated poorly with academic and work performance, casting doubt on one of the most studied phenomena in psychology and also on the ability of self-reports to capture targeted phenomena. Similarly, in an attempt to prove the value of air combat maneuvering for Air Force educators, Lawless and his colleagues (2000) found no association between air combat outcomes (wins-losses) and examination scores on air-combat knowledge. And at the end of his distinguished career in testing game matrices, Kelley (1992) found no association between the preferences as measured by surveys before games were played and the choices actually made during games. Along the same line, Axsom and Lawless (1992) found that scientists easily misinterpreted the causes of behavior measured in effort justification experiments designed to reduce public speaking anxiety even when the scientists observed the changes directly.

In their review of decision theory, Shafir and LeBoef (2002) concluded that justifications of actions already taken were not consistent with the actions taken, including for expert judges. In addition, they found that the widely held belief by theoreticians that expectations of well-being lead to well-being was systematically violated, even for experts. But even though the evidence in support of widespread claims based on self-reports does not exist, many social models continue to endorse the belief that cooperation enhances the value of social welfare more than competition. In agreement with Pfeffer and Fong, the lack of fundamentals has produced a subjective social science. In response, we take a more theoretical approach based on the impact that cooperation and dissonance have on the diminution or generation of information (Lawless & Grayson, 2004).

To summarize, metrics must not interfere with the process of measurement; doing so collapses interdependence and invokes the organizational uncertainty principle (e.g, surveys of self-esteem at the individual level by Baumeister et al., 2004; decision-making at the organizational level; Lawless & Grayson, 2004). Perceptions are integral to behavior, as the Coca-Cola Company discovered when it decided to close out its traditional Coca-Cola brand due to its inability to best Pepsi-Cola in internal taste tests (en.wikipedia.org/wiki/New_Coke). But following considerable public criticism, the firm brought back its traditional cola and re-branded it "Classic Coke". As Baumeister has re-discovered, the measurement of perceptions in interdependent states with behavior collapses the interdependence, producing static information.

We plan to study organizations with computational models. However, Bankes (2002) and Conzelmann and his colleagues (2004) have both concluded that current computational models of organizations are not predictive, principally with Agent-Based Models (ABMs). We plan two correctives: first, to test models using social configurations addressed by our organizational uncertainty model to reproduce the results of collapsed interdependent states that we have predicted and found in the field and laboratory; and second, to build bistable organizations constituted with bistable artificial agents.

Organizational Theory and Uncertainty Principle

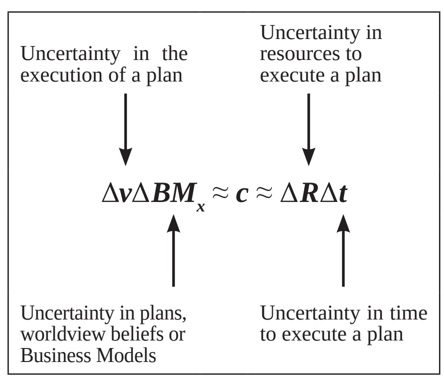
In contrast to traditional social science, we have attempted to combine individuals with organizations and systems, statics with dynamics, and empirical approaches with theory. We incorporate dynamics in our model with the effects of feedback on oscillations within an organization, but as a metric for its performance. We incorporate organizations in our model by introducing control as organizations seek to improve in performing or revising their mission (Mattick & Gagen, 2005; also, May, 1973). Finally, in our approach, an empirical approach alone precludes formal approaches and optimal solutions; our immediate goal, then, is to build and be guided by theory and empirical findings.

To implement control theory (Csete & Doyle, 2002), we need to quantify an organizational or system's level model. In line with earlier arguments, an organization controls at least four aspects of the decision-making process. First, by helping to set or choose its reference or threshold set-points (e.g., culture, decision processes, expectations, planning; and in Case Study 1, mission and vision). Second, by damping unexpected disturbances. Third, by filtering and transforming incoming information about system internal states, inputs, and responses to form patterns and decisions. Finally, by taking actions then collecting feedback to revise decisions. However, Conant and Ashby (1970) concluded that feedback to minimize errors is not an optimal solution for control, that the optimum solution avoided errors (e.g, with a plan that produces the most efficient operation possible).

As metrics for our control theory, we have proposed inverting the organizational uncertainty principle in Figure 2 to link uncertainty between planning and execution as well as between resource availability and the duration of plan execution.

In Figure 2, uncertainty in the social interaction is represented by an interdependence between business models, strategy, plans, or knowledge uncertainty (ΔBM_x, where the knowledge or business model is a function of the social location where it was learned; from Latané, 1981 and Sukthankar, 2008) and uncertainty in the rate of change in knowledge or its execution as $\Delta v = \Delta\ (\Delta BM/\Delta t)$. This relationship agrees with Levine and Moreland (2004) that as consensus for a concrete plan increases (ΔBM_x reduces), the ability to execute the plan increases (Δv increases). By extension,

Figure 2. Measurement problem



The measurement problem occurs as the result of the organizational uncertainty principle. The measurement problem arises from the interdependence between the two factors on each side of the equation. It states that both factors on either side of the equation cannot simultaneously be known exactly. For example, a decrease in the uncertainty in the strategy for an organization results in an increase in uncertainty for the execution of that strategy. In practice, decreasing strategic uncertainty increases action; increasing strategic uncertainty slows action (Busemeyer, 2008). At the same time, the uncertainty principle informs us that only one of the factors on either side of the equation can be known with certainty (Lawless et al., 2007).

interdependence also exists in the uncertainty in the resources expended to gain knowledge, ΔR, and by uncertainty in the time it takes to enact knowledge, Δt. That these two sets of bistable factors are interdependent means that a simultaneous exact knowledge of the two factors in either set is precluded, due to a collapse of interdependence. However, a partial or proportional collapse is not ruled out (i.e., tradeoffs).

We have used the model in Figure 2 to study human organizations making decisions under uncertainty by addressing complex situations like the environmental cleanup of its nuclear facilities undertaken by the Department of Energy, or mergers and acquisitions. The primary characteristic of this interdependence is reflected in tradeoffs between coordinating social objects communicating to solve problems while in states of uncertainty (Lawless & Grayson, 2004). In Case Study 1, we apply Organizational Uncertainty theory to a system of seven MDRCs (Medical Department Research Training Center). Our goal is to help those MDRCs become more productive in meeting their assigned mission. This means that the MDRC system would shift from a fragmented to a more ordered group of organizations, thereby increasing productivity. In the future, to exploit the power of the semantic web, we propose to use a rate equation to measure in real-time with machines the system performance, thus offering management insight as to the factors to change in a tradeoff that enhances organizational performance.

In addition, we have proposed that alignment of humans and thinking machines (agents) in an organization ranges from disordered in the lowest energy or individual state to one focused on the mission (Lawless et al., 2007). But, by focusing on the mission exclusively as in the latter case, organizations become vulnerable to change. Therefore, it is important to use feedback not only to fine tune an organization's effectiveness over the short term, but to restructure by revising its mission over the long term (Smith & Tushman, 2005). We propose that the tension can be best constructed, maintained and controlled over time by using semantic web-based metrics.

Evidence: Field

Department of Energy Citizen Advisory Boards

In our search for a classical organizational uncertainty principle, we have found in the field and confirmed in the laboratory a planning cognitive-execution tradeoff between consensus-seeking and majority rule decision-making as citizen groups made decisions over complex issues like nuclear waste management (Lawless et al., 2005). Two forms of consensus were found to exist: Worldview consensus and action consensus. The former is more likely to be derived from cooperative processes and the latter from competitive processes (Wood et al., 2008). In the first field study, we looked at the decisions of all nine of the Department of Energy's Citizen Advisory Boards as they responded to DOE's formal request to support DOE's plans to speed the shipments of transuranic wastes to its repository in New Mexico (i.e., the WIPP facility; see www.wipp.energy.gov) as part of its mission to accelerate the cleanup of DOE facilities across the U.S. These nine DOE Boards were geographically separated and located at the DOE sites where the transuranic wastes were being removed and shipped to WIPP. DOE's plans were entailed in 13 concrete recommendations and explained to the various Boards by DOE engineers (e.g., recommendation #8: "DOE in consultation with stakeholders and regulators initiate action to assure that WIPP has the capacity to accommodate all of the above listed TRU waste"). As predicted, four-fifths of DOE's majority-rule boards endorsed these recommendations, while three-fourths of its consensus-ruled boards rejected them. In addition, the time spent in deciding for majority-ruled boards was about one-fourth of the amount of time taken by the consensus-ruled boards.

In a follow-on field study of consensus decisions by the Hanford Board in Washington State and majority rule decisions at the Savannah River Site Board in South Carolina, Boards located at the two DOE sites with the largest cleanup budgets, we found that consensus rule decisions produced a cognitive congestion that resulted in behavioral "gridlock" when the single worldview of the Board conflicted with DOE's vision, increasing social volatility (Lawless & Whitton, 2007). We have found that cognitive congestion is more likely under cooperative decision making because of the inability to accept challenges to illusions (Lawless et al., 2008b). In contrast, we have found that the cognitive disambiguation from competition improves social welfare with practical decisions that feedback amplifies or accelerates.

Relative to the SRS-CAB, Bradbury and her colleagues (2003) analyzed interviews and other self-reported measures to conclude that Hanford CAB members felt very positive about their consensus-seeking process, that they very much wanted a cleaned-up environment, and they felt that DOE at its Hanford site was very responsive to their demands. However, the results from field metrics at DOE Hanford and DOE Savannah River Site (SRS) across three measures of cleanup (high-level radioactive wastes, transuranic wastes, and the environmental remediation of contaminated sites) indicated the opposite (e.g., Lawless et al., 2005). Compared to the SRS CAB and the SRS site, this difference between perceptions at the Hanford CAB and the results in the field represented an increase in risk perceptions (i.e, an unchecked increase in the number of illusions) among the Hanford CAB members that had kept them from making concrete recommendations to accelerate the environmental cleanup at Hanford.

Evidence: Laboratory

Preliminary data from a laboratory experiment nearing completion with college students making recommendations to improve their college experiences appears to have fully replicated the DOE CAB study. In this study, we asked college students in 3-person groups (N = 53 groups) at a Historically Black College and a nearby University to proposed open-ended recommendations to improve operations affecting them at their schools (e.g., with cafeteria food, library, student government, etc.). Students were randomly assigned to three-person groups who made recommendations either under consensus (CR) or majority rules (MR). Time for both types of groups was held constant. Tentatively, we predicted and found that while CR produces significantly more discussions (oscillations or $j\omega$), indicating less time available to craft recommendations, MR produces significantly more total recommendations (our analyses are ongoing).

Evidence: Case Study 1: Military Medical Department Research Training Centers (MDRCs)

Guided by our theoretical and field results in applying the organizational uncertainty principle, we have been assisting a system of seven military MDRCs (Wood et al., 2008) to become more productive; e.g., produce more research with greater scientific impact; improve patient care; and reduce the costs of care. Specifically, when we began this case study, we found little knowledge existed at the organizational level that directly linked each research product (publications, presentations, workshops) with MDRCs assigned mission. Instead, MDRC collected basic citations for each publication; not all publications were captured in its data-base; nor were all conferences attended captured in their data base.

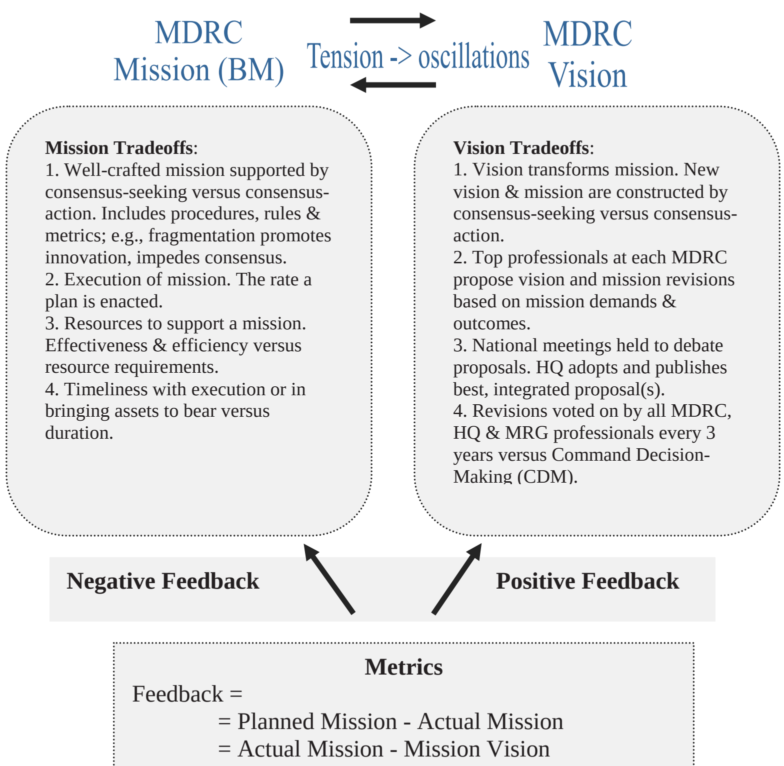
We began with a preliminary set of metrics that indicated the efficiency in meeting MDRCs mission per research protocol across the factors of scholarly activity, personnel availability, space, and funding. But at the same time, these Centers wanted to be able to transform their mission as necessary. These two goals are contradictory. But Smith and Tushman (2005) concluded that satisfying contradictory goals like these could make an organization more productive now, and more transformative in the future (see Figure 3).

Based on feedback from metrics of organizational performance linked to eIRB's, administrators have the ability to execute their mission effectively and efficiently; e.g., with Lean Six Sigma processes. But efficiency alone reduces adaptability to uncertain future missions (Smith & Tushman, 2005). Thus, concomitantly, a group internal to each MDRC and a national group of elite professionals from all MDRC units could gather annually to transform its mission, goals, and rules guided by the same feedback and metrics. As these two systems compete in a bistable relationship to control the Mission, the two systems operate in tension (interdependence), producing a natural evolution of the system.

Evidence: Case Study 1: Application of the Theoretical Model

The military (Wood, 2007) has funded a secure web-based system for one MDRC for the submission of IRB research protocols by its investigators (viz., human and animal research Institutional Review Boards). The other MDRCs are included in the product evaluation selection process in the hope that the benefits of the funded eIRB will

Figure 3. Future proposal for a semantic-web based system of seven MDRCs



The initial guidance based on theory were: Mission success makes a lean organization more efficient but also more vulnerable to change; change in a business model or its execution in reaction to environmental change was not optimum (Conant & Ashby, 1970); and a sweet spot exists where mission performance is optimum, errors are at a minimum, and at the same time the mission and the organizations it guides are modernized.

secure funding for the other sites. The first eIRB includes routing of submissions to IRB members; receipt of comments from IRB reviewers; transmission of modification requests to investigators; development of IRB meeting minutes; tracking of protocol status; automatic notification of investigators of continuing review deadlines; and tracking metrics. The technology provides a platform for collaboration across the organization between Principal Investigators and team members when drafting protocol proposals. It provides feedback among IRB reviewers, the PI and study team, and Administrators. It tracks Adverse Events (medical and drugs); provides guided electronic input and assistance and error checking and reporting to PI's and Administrators; but more importantly, it is a platform for integrated management and reporting.

The vision for this eIRB project is to achieve an end state to:

allow all research proposals, supporting documents, and scholarly products to be submitted and managed by a secured web based electronic system that allows for the real time calculation of research metrics of workload, productivity and quality. Additionally, this kind of system will allow for better management of the necessary documentation for human research protection and ensure a better environment of operational security oversight for potentially actionable medical information. This will be developed with joint execution in mind and have input from our DoD counterparts. A system that effectively captures all aspects of the research process, from protocol submission and processing to publication of scholarly products or novel therapeutics will generate the highest quality data for productivity analysis and metric development. We believe this can best be achieved by development of an electronic protocol submission and management system with the capacity to generate real time metrics of productivity and quality. (Wood, 2007, pp. 4-5)

In installing the eIRB, MDRC will be better positioned to leverage business intelligence (BI) tools that automatically pull together data for metrics with machines from this new electronic system and from other disparate database systems already in place (e.g., electronic medical records). However, only until MDRC has database systems across all aspects of biomedical research and medical care delivery and the BI tools to link these often incongruent systems together will it be able to generate real time data for semantic-web machines to study, define and improve their processes. Once in place, MDRC can make decisions in real-time rather than with data many months old thereby closing the gap between the mission and the vision and pushing the organization faster towards innovation. The natural tension and gap between the mission and vision, as it closes, will decrease the cycle time between these two perspectives propelling MDRC along the pathway of necessary transformation. We believe the ability to quickly and effectively manage knowledge is the key to organizational change.

Knowledge management is one of the fastest growing sectors in the business community. In parallel with the rapid growth of knowledge generated by automation systems, organizations having the capability and diversity of BI tools to analyze their performance against their own chosen metrics should help to accelerate system-wide transformation. These tools can afford a seamless reach across different platforms to easily allow for the automatic generation of dashboards that can visually depict metrics of organizational importance in a manner not previously available. As the present web evolves into the Semantic web, so will the capability of knowledge management with BI tools.

Current Status. A case in point to demonstrate the power of web-based technology and knowledge management has been the virtual collaboration systems used by the MDRC working group planning for an eIRB. Leaders geographically separated were able to meet approximately thirty times over almost two years and work together to solve common problems in a manner that would have been cost-prohibitive in the past. MDRC leaders from Hawaii, Washington State, Texas, Washington DC, and Georgia worked as a networked virtual organization for approximately 60 hours using web-based collaboration technology with visual and audio communication that lead ultimately to the successful funding of the eIRB system (for a review of Networked and Virtual Organizations, see Lawless et al., 2008a). Members simply logged onto the web from the convenience of their own office to participate in problem solving and closing the gap of tension between their mission and vision. Using this virtual collaboration in conjunction with a mind-mapping program (similar to a semantic network) for more effective brainstorming allowed the saving of thousands of dollars in travel and personnel time.

Assessment of Case Study One. We began Case Study 1 by contrasting the organizational performance of MDRC against the specifics listed in its assigned mission: improving patient care in the field; reducing the costs of care; and increasing the impact of research products. We found no clear link between research products and the mission; no measure of publication impacts; and no direct way to measure organizational productivity against its peers (reduced or negligible states of interdependence). In general, the organizations in the MDRC network appeared to be fragmented, with each pursuing its own path to mission success. No overarching measure of system performance existed for the MDRCs that the separate organizations could follow to guide their collective behavior. As a consequence, long-term work practices and cultural differences predominated. Subsequently, the move to adopt a web-based eIRB has set the stage to turn around the lack of organizational and system-wide knowledge. MDRC is prepared for real-time organizational and system-wide based metrics, improvements and future transformations (based on maintaining interdependent states). We believe that the semantic web can enhance these metrics by operating in real-time with data collected by machines to distinguish between classes of data sources (using OWL's vocabulary to label separately a site's physician students, physician scientists and medical scientists across the different sites, etc.). At the same time, we will be diligent in preventing web machines from either the inadvertent disclosure of patient records or the premature release, identity and location of researcher data.

Evidence: Case Study 2: Application of Theoretical Model to a College

After developing and applying metrics for a government organization whose primary mission is training military physicians in medical research practices, it was helpful to apply similar web-based metrics to an organization with a very different purpose. The subject of Case Study 2 is an organization whose primary function is higher education. Although all institutions of higher education are tasked with the production of new knowledge within fields where it offers degrees, this organization's primary purpose is to train the next generation of citizens through the use of a liberal arts curriculum. In its Vision statement, technology is highlighted and indicates that the institution "provides information technologies that link its students' total academic and social experiences to the global world." (Bradley, 2008)

Today's institutions of higher education are faced with an interesting dilemma with faculty members who have come of age during a period of tremendous technological upheaval. During the last twenty years, institutions of higher education have started making significant investments in administrative information systems. Higher education institutions are being asked by policy makers, accrediting bodies, the business community and the public for evidence that college graduates have a demonstrated knowledge base predicated on their degree. With the mounting cost of higher education, consumers are asking for accountability from colleges and universities (Bradley, 2008). Institutions of higher education as well as most organizations must focus on systems that must be in place to ensure that the decisions made in the future take advantage of the best data possible.

Institutions are engaged in a delicate dance of remaining true to their purpose in society while responding to calls for accountability for their actions. Laws such as the Family Education Rights and Privacy Act (FERPA) caused some campus officials to develop extremely strict policies regarding information about student records. These policies were strictly enforced even when it was known that the aggregation and analysis of data from student records would provide the institution with invaluable information for making informed decisions about ways to improve academic programs, increase retention, and address issues being raised by outside entities. Institutional research projects were strangled by the fear of litigation regarding the privacy of student information (Green, 2007).

According to Green (2007) "institutions of higher education have seen an emergence of a wide, rich, and mission-critical array of student and institutional services that are directly linked to core campus information services (or Enterprise Resource Planning (ERP) functions). Yet these new functions and services—alumni services, course/learning management systems, digital content, e-portfolios, e-services (online registration, fee payment), and portals—are all firmly dependent not only on the Web but also on real-time interaction with the core elements of the "old" management information system (MIS), particularly students records and institutional finances." Many of these functions at institutions, particularly small institutions are informal and units within the organization form their own fiefdoms many times as a way of managing the complexity of a system that is governed by external policies and procedures as well as the end users of the services. In an earlier age when students walked from one office to another to engage personnel in the business of enrolling in courses, acquiring financial aid, paying their bills, and obtaining housing, these systems worked. However, in an age where information drives decisions for the organization as well as the consumer, the earlier model is no longer feasible.

The organization employs approximately 200 individuals with the majority of individuals serving as instructional personnel providing instruction for a student body of less than 1,000 individuals studying at the undergraduate level. Besides instructional staff (faculty), there are administrative staff members, staff who provide support services to students, a unit that manages the fiscal enterprise of the organization, and a unit responsible for external partnerships and fund raising. All units of the institution rely on the efficient function of the other areas but are limited in the operational knowledge generated by these other units from the lack of technological (web-based) interconnectivity.

Current Status

Computing and technology support in an academic environment provide the technology infrastructure for academic and administrative activities that have become essential for the operational effectiveness of institutions of higher education. There is a need to analyze the current technology infrastructure due to the present isolation between subsystems and organizational operations. Multiple systems exist but each organizational unit works with its own "preferred" one, producing fragmentation. The different systems are not integrated causing record sharing and management problems. Currently, information technology (IT) support is being done by two staff members, one deals with hardware issues and the other with support software plus the network as part of the college's infrastructure. There is no system request form or work-list. Priority is given to network issues and calls from very important persons (VIPs) within the organization, likely impeding performance.

With a new administration, this organization has realized the need to evaluate the current IT infrastructure and the need for changes to fulfill its vision and mission. After the preliminary investigation, the first need identified was to overhaul and redesign the website. The previous version did not represent the academic organization due to its commercial feel. Then an IT inventory survey was conducted to find out what systems are available, which system is being utilized by which unit (or not at all), the merit of these choices, and the costs associated with each system. To find an enterprise-wide solution, the institution is considering having an IT-consultant company to evaluate the current infrastructure (conceptual model), and suggest the best solution. The institution also needs a chief information officer (CIO) (or MIS director) who is capable of implementing the plan.

All institutional areas that are impacted by or use technology should be evaluated. Either after purchasing an enterprise information system (EIS) or after choosing from currently available systems for a single "main" system that supports most unit functions plus a Transaction Process System (TPS) for business/financial unit online transactions, performance measurement should be enacted. Focus, however, would not be placed on the network *per se*, but on the organization's performance as measured with its EIS. Critical Success Factors for an EIS in a higher education institute like this one which should be measured are:

- Instructional support, as measured by the number of courses offered or supported via the Internet or other electronic methods, number of instructional classrooms supported, number of student computer labs, student accounts, technology in residence halls and shared spaces (i.e. campus center) or other means
- Research support, as measured by access to research databases, high speed network connectivity, other data collection and analysis mechanisms, and specialized research functions
- Cost of services, either measured in the aggregate, or on a per-student full-time equivalent (FTE) or per-faculty FTE basis, including comparisons with peer institutions
- Number of graduates compared with admission
- Student learning outcomes: assessments support

Assessment of Case Study Two

While it is too early in the process to assess this college, and while a measurable semantic-web based baseline is being built, certain areas to measure performance are already obvious. For example, after implementation of the EIS, do faculty publication numbers and the impact of research (quantity and quality) improve? Does the new IT web system improve or assist the College in its assessment processes? After the EIS system is operational, we plan to review its performance as well as the College's.

FUTURE TRENDS

The most important future trend is the use of agent-based models (ABM's) to model social and organizational effects to measure their effectiveness with the semantic web. Agent based systems have been endowed with auction based mechanisms for distributing their resources (Gibson and Troxell, 2007). In this scenario, the various entities would "bid" for the information they require, ensuring that the entity that valued the information the most would receive it in the timeliest manner for their decision making. Double auctions have been used for similar analyses with genetic algorithms (Choi, Ahn and Han, 2008).

Working with mathematics, ABM's, and artificial intelligence, the organizational uncertainty principle can be generalized to interdependent probability distribution functions with the standard deviation of Fourier transform pairs (i.e., the standard deviations from a Gaussian distribution and its Fourier transform form a "Fourier pair"; in Cohen, 1995; Rieffel, 2007). Next, we construct circuits to provide a basic model of social decision making (Yu & Efstathiou, 2002). Circuits can be modeled using virtual natural selection processes (e.g., machine learning, natural computation). Rate equations would then provide a detailed prediction of outcomes that we plan to estimate with Monte Carlo simulations. Completing the process, sensitivity analyses with the rate equation parameters provides a direct link back to the organizational uncertainty principle.

Circuits

Based on entropy measures, Yu and Efstathiou (2002) found that series network circuits underperformed parallel circuits. We expect to find that group decision-making, especially around a table, is similar to a series circuit, with subgroups or subcommittees acting like parallel circuits. However, we also expect that consensus rules (CR) will be serial and sequential, producing the time lags observed in the field and laboratory, but that majority rules (MR) with discussion drivers will act like a parallelization of neutrals, producing the time speedup also observed.

Natural Computation

Natural computation models will permit us to test field data and model the organizations that produce this data, especially the MDRC system in Case Study 1 and later the college in Case Study 2. We propose to test the data and organizational models with artificial agents evolved using biologically inspired natural selection (De Jong, 2008) and social methods of decision-making (e.g. "voting" mechanisms, ensembles). Based on our field research, we predict longer decision times and more oscillations under consensus rule (CR) than majority rule (MR). That is, we expect CR to model serial sequential individual decision processes. Surowiecki (2004) presented evidence and case studies of why agent ensembles often outperform individual experts. Earlier, Opitz and Maclin (1999) empirically showed that ensembles often outperform individuals, with theoretical support provided by Brown (2005) and Tang (2006).

Monte Carlo Simulations

Monte Carlo simulation is a technique that allows the simultaneous iteration of many uncertain variables to understand the impact of input uncertainties on one or more outcome variables. Developed during the 1940s as part of the Manhattan Project, and named after the famous casino in Monaco, Monte Carlo techniques are used today in fields ranging from manufacturing to finance, engineering and life sciences.

The basic concept in Monte Carlo simulation is that each uncertain variable, which we call a random variable, is simulated by a probability distribution. For each trial of a simulation, each random variable is sampled from its corresponding probability distribution and the sampled value is used to compute the output variable(s) for the model. Many such trials are conducted and a value is collected for each outcome variable for each simulation trial. At the conclusion of all trials a distribution of outcomes can be constructed to better understand the distribution of uncertainties for an outcome given the uncertainties in the input variables.

Rate Equation

Lawless and his colleagues (2007) devised a mathematical model of social interaction rates (this approach will allow future tests of this model constructed with machine learning using recombination operators; De Jong, 2008). We propose to adapt this model to guide our future research on organizations, e.g., training MDRC physicians with the experimental method or educating students unprepared for college courses with enhancement classes. In the latter case, the model becomes,

$$\Gamma = N_1 N_2 v_{12} \sigma_{12} \, exp \, (-\Delta A/<A>), \tag{1}$$

where Γ is the college graduation rate; N_1 the population in the group of those who have learned; N_2 those in the population who have not yet learned; v_{12} represents the velocity of knowledge passed between them, with the minimum effect occurring under censorship; σ_{12} represents how well the two groups match their beliefs, with the maximum effect occurring under social agreement (resonance); and $exp\ (-\Delta A/<A>)$ represents the probability of graduation or knowledge exchanges, where ΔA represents the energy or effort required for the knowledge to be acquired, and $<A>$ represents the average amount of effort being expended by the targeted HBCU, its professors and support staff, and its fellow students. Before we address the implications of equation (1), let's rearrange it. If χ represents the knowledge required before a student can be declared to become a graduate, then $\Gamma = \partial\chi/\partial t \approx \Delta\chi/\Delta t$, and

$$\Delta\chi = \Delta t \, N_1 N_2 v_{12} \sigma_{12} \, exp \, (-\Delta A/<A>). \tag{2}$$

From equation (2), given an average time to matriculate from the target HBCU, various opportunities exist as tradeoffs for it as an organization to improve the probability that one of its students will graduate ($\Delta\chi$) from this college. Increasing the numbers of those who actively support the student increases the occurrence of teacher-support group (N_1) to student (N_2) speech acts. Increasing the velocity (v_{12}) of knowledge passed between the two groups improves the acquisition of knowledge. Increasing the match (σ_{12}) between faculty-support groups and student groups can dramatically increase the knowledge gained (e.g., study groups; student focus groups; faculty-student focus groups; *enhancement* groups). But also the probability of graduation can be increased by reducing barriers for students ($-\Delta A$; e.g., either lowering requirements, choosing better qualified entrants, or *enhancing* the skills of the weaker entrants). Finally, by increasing the overall average effort or excitement by the HBCU directed toward learning and graduation ($<A>$), a college can strongly improve the odds that its students will graduate. Inversely, changing these factors can also decrease or adversely increase the time required for graduation.

Using the equations that we have laid out, with machines automatically collecting the data over the semantic web, we believe that real-time metrics will become possible. This information will not only be able to inform colleges or MDRCs whether they are on-target to achieve their mission as they themselves have defined it, but whether they are making progress evolving into the vision that they themselves have also proposed. With machine readable data feeding real-time metrics, organizations like MDRC will also be able to tune their performance. For the first time, we will know the actual cost of controlling their organizations to realize their benefits.

CONCLUSION

A preliminary web-based metric modeled after the plans for the new semantic web Health Care and Life Sciences Interest Group (HCL SIG) using electronic spreadsheets indicates that researcher protocol effectiveness can be established and measured as part of an organization's mission. In the metric, for theoretical reasons we have chosen the interdependent factors of planning-execution and resources-timing. As a result, the organizational uncertainty principle has proven to be a fertile source for theory and a tool to guide a system of military units in the field as they move into a new web-based collaboration system, and for a college as it begins to establish a web-based EIS system with real-time metrics. Future trends and our next steps along the path forward with natural computation, Monte Carlo simulation and Agent-Based Models (ABM's) were also reviewed. Finally, we will assure that semantic web machines do not inadvertently disclose patient records nor prematurely release data from researchers.

KEY TERMS AND DEFINITIONS

Bistability: Bistability occurs when one data set produces two mutually exclusive interpretations that cannot be held in awareness simultaneously (Cacioppo et al., 1996). Bohr (1955) concluded that multiple interpretations support the existence of different cultures. Further, given the importance of feedback to social dynamics (Lawless et al., 2007), rapid shifts between bistable perceptions increase uncertainty in the non-observed perception which not only underwrites social problems between different groups, but also supports the existence of an uncertainty principle.

Game Theory: Game theory was invented in the 1940's by Von Neuman & Morgenstern (1953). It is a one-shot game, or repeated games, played by 2 or more agents. In its most basic form, the game configuration presents two choices for payoffs to each player. Payoffs are interdependent. The values in the configuration of choices offered to participants are arbitrary and normative.

Health Care and Life Sciences Interest Group: The Semantic Web includes a Health Care and Life Sciences Interest Group (HCLSIG, 2008) to establish interoperable data standards for "connected knowledge" to improve collaboration across the health care and life sciences. The goal for HCLSIG is to reduce medical errors, increase physician efficiency and advance patient care and satisfaction. It includes document annotation and rule processing (with XML formats, OWL ontologies and SWRL rule processors).

Organizations: Organizations are social collectives performing a function that often cannot be done by an individual alone. Organizations do this by assigning interdependent roles to individuals, which requires coordinating the output of individuals, but also amplifies the capabilities of the individual working alone (Ambrose, 2001).

Organizational Uncertainty Principle: The organizational uncertainty principle acts as a tradeoff in attention directed at reducing the uncertainty in one factor, such as a worldview, with the result that the uncertainty in a second interdependent factor is increased inversely. It is based on Bohr's (1955) famous notion that the uncertainty principle at the atomic level applied to social situations is captured by human action and observation. That is, the more focused individuals are on acting out a series of steps, the less observant they become of their action. Applied to societies, action-observation uncertainty couples that open the path to multiple interpretations of the same social behavior lie at the root of different cultures.

Semantic Web: The Semantic Web is an on-going project to extend the World Wide Web (WWW) to permit humans and machines to collaborate efficiently. As envisioned by Berners-Lee (2007), inventor of WWW (and web languages URI, HTTP, and HTML), the future Web should evolve into a universal exchange for data, information and knowledge. Without a universal standard for machine access, HTML data is difficult to use on a large scale. The Semantic Web solves this problem with an efficient global mesh for information access by humans and machines.

Social Learning Theory: SLT is a term coined by Bandura (1977) that includes the three different schools of ideas that accounted for learning by organisms, but with a primary focus on humans. These three schools were classical conditioning (Pavlovian associations), operant conditioning (Skinnerian rewards and punishments), and modeling, Bandura's own school of thought.

Chapter 7.2
Bridging the Gap between Mobile Application Contexts and Web Resources

ABSTRACT

Context-awareness is highly desired, particularly in highly dynamic mobile environments. Semantic Web Services (SWS) address context-adaptation by enabling the automatic discovery of distributed Web services based on comprehensive semantic capability descriptions. Even though the appropriateness of resources in mobile settings is strongly dependent on the current situation, SWS technology does not explicitly encourage the representation of situational contexts. Therefore, whereas SWS technology supports the allocation of resources, it does not entail the discovery of appropriate SWS representations for a given situational context. Moreover, describing the complex notion of a specific situation by utilizing symbolic SWS representation facilities is costly, prone to ambiguity issues and may never reach semantic completeness. In fact, since not any real-world situation completely equals another, a potentially infinite set of situation parameters has to be matched to a finite set of semantically defined SWS resource descriptions to enable context-adaptability. To overcome these issues, the authors propose Mobile Situation Spaces (MSS) which enable the description of situation characteristics as members in geometrical vector spaces following the idea of Conceptual Spaces (CS). Semantic similarity between situational contexts is calculated in terms of their Euclidean distance within a MSS. Extending merely symbolic SWS descriptions with context information on a conceptual level through MSS enables similarity-based matchmaking between real-world situation characteristics and predefined resource representations as part of SWS descriptions. To prove the feasibility, the authors provide a proof-of-concept prototype which applies MSS to support context-adaptation across distinct mobile situations.

DOI: 10.4018/978-1-60566-290-9.ch009

INTRODUCTION

Current and next generation wireless communication technologies will encourage a widespread use of available resources – data and services - via a broad range of mobile devices resulting in the demand for a rather context-adaptive resource retrieval. Context-adaptation is a highly important feature across a wide variety of application domains and subject to intensive research throughout the last decade (Dietze, Gugliotta & Domingue, 2007; Schmidt & Winterhalter, 2004; Gellersen, Schmidt & Beigl, 2002). Whereas the context is defined as the entire set of surrounding situation characteristics, each individual situation represents a specific state of the world, and more precisely, a particular state of the actual context (Weißenberg, Gartmann & Voisard, 2006). Particularly, a situation description defines the context of a specific situation, and it is described by a combination of situation parameters, each representing a particular situation characteristic. Following this definition, context-adaptation can be defined as the ability of Information Systems (IS) to adapt to distinct possible situations.

To achieve this, we base on a promising technology for distributed and highly dynamic service oriented applications: Semantic Web Services (SWS). SWS technology (Fensel et al., 2006) addresses context-adaptation by means of automatic discovery of distributed Web services as well as underlying data for a given task based on comprehensive semantic descriptions. First results of SWS research are available in terms of reference ontologies – e.g. OWL-S (Joint US/EU ad hoc Agent Markup Language Committee, 2004) and WSMO (WSMO Working Group, 2004) – as well as comprehensive frameworks (e.g. DIP project[1] results). However, whereas SWS technology supports the allocation of appropriate services for a given goal based on semantic representations, it does not entail the discovery of appropriate SWS goal representations for a given situation. Particularly in mobile settings, the current situation of a user heavily determines the intentional scope behind a user goal and consequently, the appropriateness of particular resources. For instance, when attempting to retrieve localized geographical information, the achievement of a respective goal has to consider the location and device of the user.

Despite the strong impact of a (mobile) context on the semantic meaning and intention behind a user goal, current SWS technology does not explicitly encourage the representation of domain situations. Furthermore, the symbolic approach - describing symbols by using other symbols without a grounding in the real world - of established SWS and Semantic Web (SW) representation standards in general, such as RDF (World Wide Web Consortium, W3C, 2004a), OWL (World Wide Web Consortium, W3C, 2004b), OWL-S (Joint US/EU ad hoc Agent Markup Language Committee, 2004), or WSMO (WSMO Working Group, 2004), leads to ambiguity issues and does not entail semantic meaningfulness, since meaning requires both the definition of a terminology in terms of a logical structure (using symbols) and grounding of symbols to a conceptual level (Cregan, 2007; Nosofsky, 1992).Moreover, while not any situation or situation parameter completely equals another, the description of the complex notion of a specific situation in all its facets is a costly task and may never reach semantic completeness. Apart from that, to enable context-adaptability, a potential infinite set of (real-world) situation characteristics has to be matched to a finite set of semantically defined parameter representations. Therefore, we claim, that fuzzy classification and matchmaking techniques are required to extend and exploit the current functionalities provided by SWS and match the specific requirements of context-aware mobile applications.

Conceptual Spaces (CS), introduced by Gärdenfors (Gärdenfors, 2000; Gärdenfors, 2004) follow a theory of describing entities at the conceptual level in terms of their natural characteristics similar to natural human cognition in order to avoid the symbol grounding issue. CS enable representation of objects as vector spaces within a geometrical space which is defined through a set of quality dimensions. For instance, a particular color may be defined as point described by vectors measuring the quality dimensions hue, saturation, and brightness. Describing instances as vector spaces where each vector follows a specific metric enables the automatic calculation of their semantic similarity, in terms of their Euclidean distance, in contrast to the costly representation of such knowledge through symbolic SW representations. Even though several criticisms have to be taken into account when utilizing CS (Section 0) they are considered to be a viable option for knowledge representation.

In this chapter, we propose Mobile Situation Spaces (MSS) as a specific derivation of Conceptual Situation Spaces (CSS). MSS utilize CS to represent situations and are mapped to standardized SWS representations to enable first, the situation-aware discovery of appropriate SWS descriptions and finally, the automatic discovery and invocation of appropriate Web services to achieve a given task within a particular situation. Extending merely symbolic SWS descriptions with context information on a conceptual level through MSS enables a fuzzy, similarity-based matchmaking methodology between real-world situation characteristics and predefined SWS representations within mobile environments. Since semantic similarity between situation parameters within a MSS is indicated by the Euclidean distance between them, real-world situation parameters are classified in terms of their distance to predefined prototypical parameters, which are implicit elements of a SWS description. Whereas current SWS technology addresses the issue of allocating services for a given task, our approach supports the discovery of SWS task representations within a given mobile situation. Consequently, the expressiveness of current SWS standards is extended and fuzzy matchmaking mechanisms are supported.

To prove the feasibility of our approach, a proof-of-concept prototype is provided which uses MSS to support context-adaptation by taking into account context parameters such as the current location and desired knowledge subject.

The paper is organized as follows. The following Section 2 provides background information on SWS, whereas Section 3 introduces our approach of Conceptual Situation Spaces which are aligned to current SWS representations. Section 4 illustrates the application of CSS to mobile settings by introducing MSS. Utilizing MSS, we introduce a context-adaptive prototype in Section 5. Finally, we conclude our work in Section 6 and provide an outlook to future research.

SEMANTIC WEB SERVICES AND WSMO

SWS technology aims at the automatic discovery, orchestration and invocation of distributed services for a given user goal on the basis of comprehensive semantic descriptions. SWS are supported through representation standards such as *WSMO* and *OWL-S*. We refer to the *Web Service Modelling Ontology (WSMO)*, a well established SWS reference ontology and framework. The conceptual model of WSMO defines the following four main entities:

- *Domain Ontologies* provide the foundation for describing domains semantically. They are used by the three other WSMO elements. WSMO domain ontologies not only support Web service related knowledge representation but semantic knowledge representation in general.
- *Goals* define the tasks that a service requester expects a Web service to fulfill. In this sense they express the requester's intent.
- *Web service* descriptions represent the functional behavior of an existing deployed Web service. The description also

outlines how Web services communicate (*choreography*) and how they are composed (*orchestration*).
- *Mediators* handle data and process interoperability issues that arise when handling heterogeneous systems.

WSMO is currently supported through several software tools and runtime environments, such as the *Internet Reasoning Service IRS-III* (Cabral et al., 2006) and WSMX (WSMX Working Group, 2007). IRS-III is a *Semantic Execution Environment (SEE)* that also provides a development and broker environment for SWS following WSMO. IRS-III mediates between a service requester and one or more service providers. Based on a client request capturing a desired outcome, the goal, IRS-III proceeds through the following steps utilizing the set of SWS capability descriptions:

1. Discovery of potentially relevant Web services.
2. Selection of set of Web services which best fit the incoming request.
3. Invocation of selected Web services whilst adhering to any data, control flow and Web service invocation constraints defined in the SWS capabilities.
4. Mediation of mismatches at the data or process level.

In particular, IRS-III incorporates and extends WSMO as core epistemological framework of the IRS-III service ontology which provides semantic links between the knowledge level components describing the capabilities of a service and the restrictions applied to its use.

However, even though SWS technologies enable the dynamic allocation of Web services for a given goal, it does not consider the adaptation to different user contexts. In order to fully enable context-aware discovery of resources as required by mobile settings (Section 1), the following shortcomings have to be considered:

I1. *Lack of explicit notion of context*: current SWS technology does not entirely specify how to represent domain contexts. For example, WSMO addresses the idea of context: Goal and web service represent the user and provider local views, respectively; the domain ontologies define the terminologies used in each view; and the mediators are the semantic bridges among such distinct views. However, WSMO does not specify what a context description should define and how the context elements should be used.

I2. *Symbolic Semantic Web representations lack grounding to conceptual level*: the symbolic approach, i.e. describing symbols by using other symbols, without a grounding in the real world, of established SWS, and Semantic Web representation standards in general, leads to ambiguity issues and does not entail semantic meaningfulness, since meaning requires both the definition of a terminology in terms of a logical structure (using symbols) and grounding of symbols to a conceptual level (Cregan, 2007; Nosofsky, 1992).

I3. *Lack of fuzzy matchmaking methodologies*: Describing the complex notion of a specific situation in all its facets is a costly task and may never reach semantic completeness. Whereas not any situation and situation parameter completely equals another, the number of (predefined) semantic representations of situations and situation parameters is finite. Therefore, a possibly infinite set of given (real-world) situation characteristics has to be matched to a finite set of predefined parameter instance representations which are described within an IS. Consequently, fuzzy classification and matchmaking techniques are required to classify a real-world situation based on a limited set of predefined parameter descriptions.

CONCEPTUAL SITUATION SPACES

To address the issues I1 - I3 introduced in Section 0, we propose *Mobile Situation Spaces (MSS)* as a setting-specific realisation of our metamodel for *Conceptual Situation Spaces (CSS)* (Dietze, Gugliotta & Domingue, 2008).

CSS Formalisation

CSS enable the description of a particular situation as a member of a dedicated CS. As defined in (Weißenberg et al., 2006) a situation is defined as:

$$S^n = \left\{ \left(t_1, t_2, cp_1, cp_2, .., cp_n \right) \middle| cp_i \in CP \right\}$$

Where t_1 is the starting time of a situation, t_2 represents the end time of a situation and cp_i being situation parameters which are invariant throughout the time interval defined through t_1 and t_2. Referring to (Gärdenfors, 2004; Raubal, 2004), we define a CSS (*css:Conceptual Situation Space* in Figure 1) as a vector space:

$$C^n = \left\{ \left(c_1, c_2, ..., c_n \right) \middle| c_i \in C \right\}$$

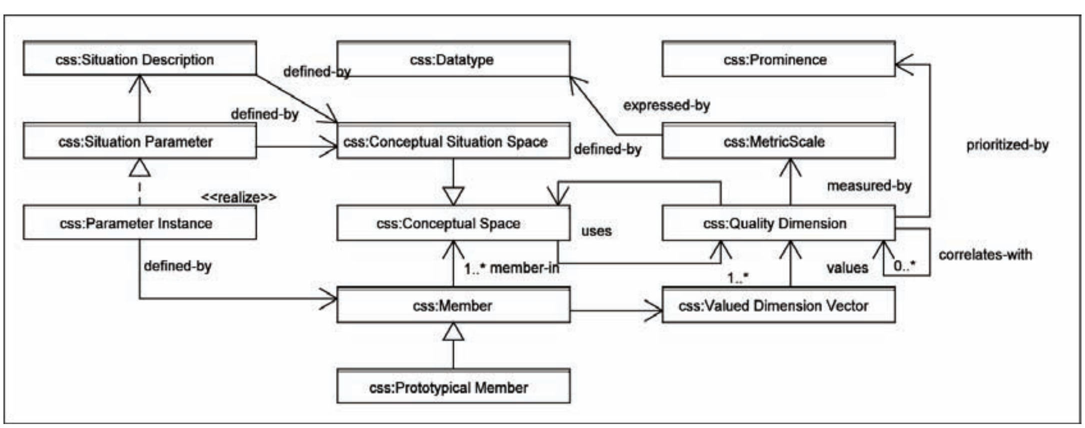
with c_i being the quality dimensions *(css:Quality Dimension)* of *C*. In that, a CSS *C* represents a particular situation *S* whereas its situation parameters cp_i are represented through certain quality dimensions c_i. Please note, that we do not distinguish between dimensions and domains - beings sets of integral dimensions (Gärdenfors, 2004) - but enable dimensions to be detailed further in terms of subspaces. Hence, a dimension within one space may be defined through another conceptual space by using further dimensions (Raubal, 2004). In such a case, the particular quality dimension c_j is described by a set of further quality dimensions with

$$c_j = D^n = \left\{ \left(d_1, d_2, ..., d_n \right) \middle| d_k \in D \right\}.$$

In this way, a CSS may be composed of several subspaces and consequently, the description granularity of a specific situation can be refined gradually. To reflect the impact of a specific quality dimension on the entire CSS, we consider a prominence value *p (css:Prominence)* for each dimension. Therefore, a CSS is defined by

$$C^n = \left\{ \left(p_1 c_1, p_2 c_2, ..., p_n c_n \right) \middle| c_i \in C, p_i \in P \right\}$$

Figure 1. The CSS metamodel.



where *P* is the set of real numbers. However, the usage context, purpose and domain of a particular CSS strongly influence the ranking of its quality dimensions. This clearly supports our position of describing distinct CSS explicitly for specific domains only.

Particular members (*css:Member*) in the CSS are described through a set of valued dimension vectors (*css:Valued Dimension Vectors*). Symbolic representations of domain situations and parameters, such as *css:Situation Description* and *css:Situation Parameter*, refer to particular CSS *(css:Conceptual Situation Space)* whereas parameter instances are represented as members *(css:Member)*.

Moreover, referring to Gärdenfors (2004) we consider prototypical members (*css:Prototypical Member*) within a particular space. Prototypical members enable the classification of any arbitrary member *m* within the a specific CSS, by simply calculating the Euclidean distances between *m* and all prototypical members in the same space to identify the closest neighbours of *m*. For instance, given a CS to describe apples based on their shape, taste and colour, a green apple with a strong and fruity taste may be close to a prototypical member representing the typical characteristics of the Granny Smith species. Figure 1 depicts the CSS metamodel.

The metamodel introduced above has been formalized into a *Conceptual Situation Space Ontology (CSSO)*, utilizing OCML (Motta, 1998). In particular, each of the depicted entities is represented as a concept within CSSO whereas associations are reflected as their properties in most cases. The correlation relationship indicates whether two dimensions are correlated or not. For instance, when describing an apple the quality dimension describing its sugar content may be correlated with the taste dimension. Information about correlation is expressed within the CSSO through axioms related to a specific quality dimension instance. CSSO is aligned to a well-known foundational ontology: the Descriptive Ontology for Linguistic and Cognitive Engineering (DOLCE) (Gangemi, Guarino, Masolo, Oltramari, Schneider, 2002) and, in particular, its module Descriptions and Situations (D&S) (Gangemi, Mika, 2003). The aspect of gradually refining a CSS through subspaces corresponds to the approach of DOLCE D&S to gradually refine a particular description by using parameters where each parameter can be described by an additional description.

With respect to (Raubal, 2004), we define the semantic similarity between two members of a space as a function of the Euclidean distance between the points representing each of the members. However, we would like to point out, that distinct distance metrics, such as the Taxicab or Manhattan distance (Krause, 1987), could be considered, even though the nature of the space and its possible metrics suggests the Euclidean distance as a useful metric to calculate similarities. Applying a formalization of CS proposed in Raubal (2004) to our definition of a CSS, we formalize the Euclidean distance between two members in a CSS as follows. Given a CSS definition *C* and two members represented by two vector sets *V* and *U*, defined by vectors v_0, v_1, …,v_n and u_1, u_2,…,u_n within *C*, the distance between *V* and *U* can be calculated as:

$$\left|d(u,v)\right|^2 = \sum_{i=1}^{n} (z(u_i) - z(v_i))^2$$

where $z(u_i)$ is the so-called Z-transformation or standardization (Devore, Peck, 2001) from u_i. Z-transformation facilitates the standardization of distinct measurement scales which are utilized by different quality dimensions in order to enable the calculation of distances in a multi-dimensional and multi-metric space. The z-score of a particular observation u_i in a dataset is calculated as follows:

$$z(u_i) = \frac{u_i - \bar{u}}{s_u}$$

where $\bar{u}$ is the mean of a dataset *U* and s_u is the standard deviation from *U*. Considering prominence values p_i for each quality dimension *i*, the Euclidean distance *d(u,v)* indicating the semantic similarity between two members described by vector sets *V* and *U* can be calculated as follows:

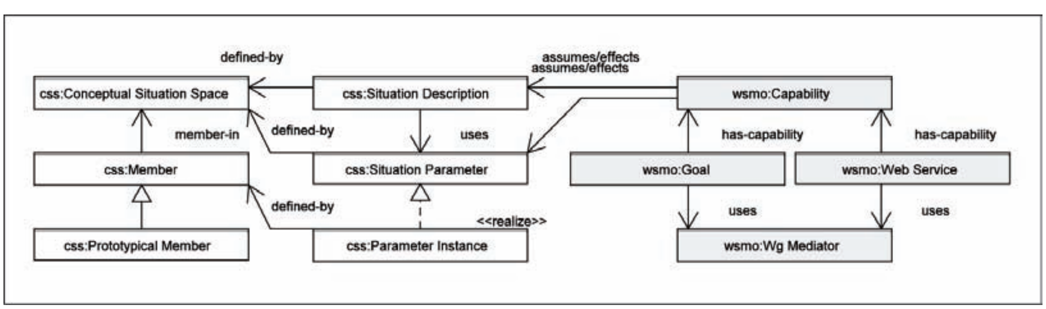
$$d(u,v) = \sqrt{\sum_{i=1}^{n} p_i((\frac{u_i - \bar{u}}{s_u}) - (\frac{v_i - \bar{v}}{s_v}))^2}$$

Utilizing CSS for SWS Selection

Whereas the discovery of distributed Web services for a given user goal is addressed by current SWS technology, such as WSMO, and corresponding reasoners, the context-aware selection of a specific SWS goal representation for a given situation is a challenging task to be tackled when developing SWS-driven applications. By providing an alignment of CSS and SWS, we address this issue by enabling the classification of an individual situation along predefined situation descriptions - used within SWS descriptions - based on semantic similarity calculation. Therefore, CSS are aligned to WSMO to support the automatic discovery of the most appropriate goal representation for a specific situation. Since both metamodels, WSMO as well as CSS, are represented based on the OCML representation language (Motta, 1998), the alignment was accomplished by defining relations between concepts of both ontologies as depicted in Figure 2.

Grey colored concepts in Figure 2 represent concepts of WSMO. A goal description (*wsmo:Goal*) utilizes particular situation parameters (*css:Situation Parameters*) to semantically describe its capabilities, i.e. its assumptions, effects, preconditions and postconditions in terms of semantic situation descriptions *(css:Situation Description)*. A WSMO runtime reasoning engine utilizes capability descriptions to identify SWS (*wsmo:Web Service*) which suit a given Goal. In contrast, the preliminary selection of the most appropriate goal description for a given situation is addressed by classification of situation parameters through CSS. For instance, given a set of real-world situation parameters, described as members in a CSS, their semantic similarity with predefined prototypical parameters *(css:Prototypical Member)* is calculated. Given such a classification of a particular real-world situation, a goal representation which assumes matching prototypical parameter instances is selected and achieved through the reasoning engine.

Figure 2. Alignment of CSS and WSMO.



Deriving CSS for Certain Application Contexts

As stated in Gärdenfors (2000), the definition and prioritization of quality dimensions within a CS is highly dependent on the purpose and context of the space. For instance, when describing an apple, dimensions may be differently weighted, dependent on whether the apple is subject to visual cognition exclusively or to full sensory perception, what would be the case if the apple is supposed to be eaten. Whereas in the first case, dimensions such as color and shape are highly ranked, taste and texture may additionally be important in the latter case.

Consequently, the derivation of an appropriate space for a certain purpose is considered an important task which usually should be carried out by a qualified individual such as an application designer. We particularly foresee a procedure consisting of the following steps:

S1. Identification of situation parameters eligible for representation as quality dimension c_i.
S2. Assignment of prominence values p_i to each quality dimension c_i
S3. Assignment of metrics to each quality dimension c_i.

With respect to *S1*, one has to take into account which aspects of a situation are relevant from an application perspective, i.e. which characteristics have an impact on the applied context adaptation strategy or rules. In the case of our intended usage of CSS for SWS selection, only parameters are important, which are considered within SWS capability representations (Section 0).

Since several dimensions might have a different impact factor on the entire space, *S2* is aimed at assigning a prominence value p_i to each dimension c_i. Prominence values should usually be chosen from a predefined value range, such as 0...1. However, since the assignment of prominences to quality dimensions is of major importance for the semantic meaning of calculated distances within a space, this step is not straightforward and most probably requires ex post re-adjustment.

During the final step *S3*, a quantitative metric has to be assigned to each previously defined dimension. Whereas certain dimensions naturally are described using qualitative measurements, such as a size or a weight, other dimensions are usually described using rather qualitative values. The latter applies for instance to the notion of a color. In case no quantitative metric can be assigned to a certain quality dimension c_i, a subspace has to be defined which refines the particular dimension through further dimensions. For instance, in the case of the color dimension, a subspace could be defined using the quantitative dimensions hue, saturation and brightness. Hence, the proposed procedure has to be repeated iteratively until a sufficient description depth has been achieved leading to the definition of a CSS *C* of the form (Section 0):

$$C^n = \left\{ \left(p_1 c_1, p_2 c_2, \ldots, p_n c_n \right) \middle| c_i \in C, p_i \in P \right\}$$

A MOBILE SITUATION SPACE

Following the steps introduced in Section 0, we derive a CSS aimed at representing situations in mobile settings. A mobile situation is defined by parameters such as the technical environment used by a user, his/her current objectives and particularly the current location. Since each of these parameters apparently is a complex theoretical construct, most of the situation parameters cannot be represented as a single quality dimension within the CSS, but have to be represented as dedicated subspaces which are defined by their very own dimensions (Section 0). Moreover, applying CSS to represent a particular concept is only reasonable in cases where similarity calculation is possible and semantically meaningful, i.e. a particular measurement can be applied to each quality dimension. For instance, the native language of a user is a crucial important situation parameter, but in this case, only a direct match is reasonable in order to provide appropriate information resources in the correct language to the user.

Therefore, this section focuses exemplarily on the representation of two parameters through a CSS subspace, which are of particular interest: the *location* and the *subject* a user is interested in. Due to the complex and diverse nature of a particular subject or spatial location, traditional symbolic representation approaches of the Semantic Web are supposed to fail since it is nearly impossible to define either a subject or a location in a non-ambiguous and comprehensive way by just following a symbolic approach.

Moreover, a one-to-one matchmaking between different locations and subjects is hard to achieve, since fairly not any instance of these parameters completely equals another one. Therefore, fuzzy similarity detections, as enabled through MSS, have to be utilized.

To represent spatial locations, we define a CSS subspace L with 2 quality dimensions l_i representing the latitude and longitude of a particular location

$$L^2 = \left\{ \left(l_1, l_2 \right) \middle| l_i \in L \right\}$$

In order to represent a particular subject, we currently consider 4 dimensions (history, geography, culture, languages) which are used to describe the semantic meaning of a particular subject within subspace S:

$$S^4 = \left\{ \left(s_1, s_2, s_3, s_4 \right) \middle| s_i \in L \right\}$$

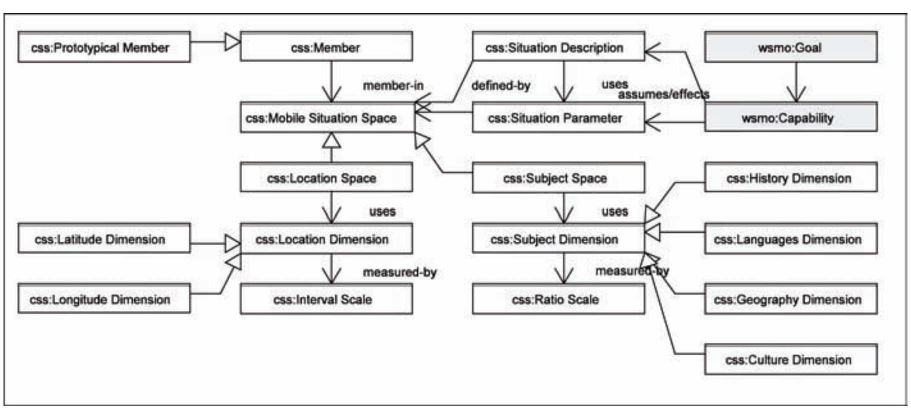
Figure 3 depicts the key concepts of the ontology describing L and S as subspaces (*css:Location Space, css:Subject Space*) within the mobile space *(css:Mobile Situation Space)*.

Moreover, Figure 3 depicts the relation of the subspace L (*css:Location Space*) and subspace S (*css:Subject Space*) with WSMO-based SWS descriptions, represented via grey-colored concepts (Section 0).

Instances of a situation parameter representing a subject are defined by particular members within the space S (*css:Subject Space*), which itself uses 4 quality dimension c_i, whereas instances of a parameter representing a spatial location are defined by members within the space L (*css:Location Space*), which itself uses 4 quality dimension $l_{i.}$ The metric scale, datatype and value range for each dimension s_i and l_i are presented in Table 1:

As depicted in Table 1, each quality dimension l_i is ranked on an interval scale with value ranges being float numbers between -90 and +90 in case of the latitude and between -180 and +180

Figure 3. Key concepts representing mobile situation subspaces.



in case of the longitude. Furthermore, each quality dimension c_i is ranked on a ratio scale with value ranges being float numbers between 0 and 100. The authors would like to highlight, that no prominence values have been assigned since each dimension has an equal impact to define a particular member. It is obvious, that the assignment of prominence values is a highly subjective process, strongly dependent on the purpose, context and individual preferences. Therefore, future work is aimed at enabling users to assign rankings of quality dimensions themselves in order to represent their individual priorities regarding the service retrieval process.

To classify an individual mobile situation, we define prototypical members (*css:Prototypical Member*) in the Mobile Situation Space. For instance, to describe particular cities as members within *L*, we utilized geodata, retrieved from GoogleMaps[2], to describe a prototypical member for each location which is targeted by a particular SWS. A few examples of prototypical location members used in the current prototype application are represented in Table 2:

An example of how such parameters are represented in a formal knowledge modeling language is given in Section 0. Moreover, we predefined several prototypical subjects in *S*, each representing the maximum value of a particular quality dimension s_i what resulted in the following 4 prototypical subjects.

Apart from the depicted subjects, each subject which is described as part of a symbolic SWS capability representation had been referred to an individual member in *S*.

Table 1. Metric scale, range, and data type of quality dimensions l_i and s_i.

	Quality Dimension	Metric Scale	Data-type	Range
l_1	Latitude	Interval	Float	-90..+90
l_2	Longitude	Interval	Float	-180..+180
s_1	History	Ratio	Float	0..100
s_2	Culture	Ratio	Float	0..100
s_3	Geography	Ratio	Float	0..100
s_4	Language	Ratio	Float	0..100

SIMILARITY-BASED SWS SELECTION AND ACHIEVEMENT IN A MOBILE SETTING

To prove the feasibility of our approach, we provide a proof-of-concept prototype application, which utilizes MSS (Section 4) - based on the CSS metamodel introduced in Sections 0 - and supports context-adaptation in a mobile environment based on SWS and CSS.

Runtime Support for CSS and SWS

The following Figure 4 depicts the general architecture adopted to support reasoning on MSS and SWS in distinct domain settings through a Semantic Execution Environment (SEE), which in our case is IRS-III (Section 0).

Multiple mobile devices - such as PDAs, mobiles or any other portable device hosting a Web browser - can serve as user interface of the

SEE, enabling the user (and the device itself) to provide information about his/her goal and the current real-world situation.

The SEE makes use of semantic representations of the CSS formalisation (CSS ontology, CSSO), specifically derived for mobile settings, and of SWS annotations based on WSMO in order to discover and allocate the most appropriate resource for a given user goal within a current situation. Ontologies had been represented using the OCML knowledge modeling language (Motta, 1998).

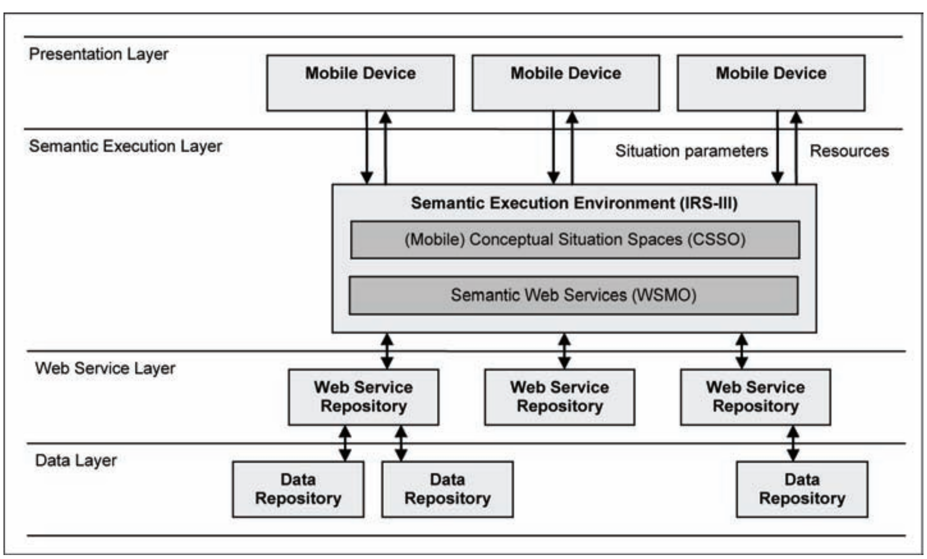
WSMO capabilities are represented by defining the assumptions and effects of available SWS and goals in terms of certain situation description or situation parameter instances (Section 0). Such situation descriptions are refined as particular prototypical members of an associated CSS, such as prototypical members of the MSS S and L introduced in Section 4.

As mentioned in Section 3, CSSO allows us to describe a specific mobile situation description instance in terms of a collection of situation parameter instances. Mobile situation description instances are automatically and gradually defined at runtime by the SEE as the result of the user interaction with the mobile device. On the basis of the detected context parameters, the SEE performs the following steps:

1. Computation of similarities between the detected real-world context parameters—obtained from the user and its device—and symbolic representation of prototypical situation parameters;
2. Progressive update of the current mobile situation description with the closest prototypical situations parameters;
3. Determination of (WSMO) goal matching the refined situation description;
4. Achievement of selected goals by means of discovery and orchestration of available web services.

Consequently, we enable the classification of real-world context parameters along available predefined parameters in order to enable a similarity-based selection and orchestration WSMO goals.

Figure 4. Architecture to support runtime reasoning on CSS and SWS.



Context Classification and Adaptation

As outlined in the previous section, the SEE automatically detects the semantic similarity of specific situation parameters with a set of predefined prototypical parameters to enable the allocation of context-appropriate resources. In this section, we further detail these aspects, since they are central in the contribution of this chapter. In particular, we specify the concepts of classification and adaptation.

Referring to CSS subspaces L and S described in Section 0, given a particular member U in L or S, its semantic similarity with each of the prototypical members is indicated by their Euclidean distance. Since we utilize spaces described by dimensions which each use the same metric scale and no prominence value, the distance between two members U and V can be calculated disregarding a Z-transformation (Section 0) for each vector:

$$d(u,v) = \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}$$

Please note, that it would be possible to calculate distances either between entire situations (members within *css:Mobile Situation Space*) or between particular parameter (members in subspaces such as L and S). Since individual semantic similarities between instances of parameters such as the current location or the desired subject are usually important knowledge when deciding about the appropriateness of resources for a given context, the current application calculates distances between each parameter, i.e. between members within each individual subspace.

The calculation of Euclidean distances using the formula shown above is performed by a standard Web service, which is annotated as SWS and invoked through IRS-III at runtime. Given a particular CSS description, a member (representing a specific parameter instance) as well as a set of prototypical member descriptions (representing prototypical parameter instances), similarities are calculated by the Web service at runtime in order to classify a given situation parameter.

For instance, a user is currently located in Eastbourne (UK) and is interested in historical information about the surrounding area. Consequently, the particular situation description (*css:MobileSituation Desccription*) includes a location parameter which is defined by a member E in the specific location space (*css:Location Space*) with the following vectors describing latitude and longitude of Eastbourne:

$$E = \left\{ \left(e_1 = 50.766868, e_2 = 0.284804 \right) \middle| e_i \in L \right\}$$

To represent the current aim of the user, a user selects one of the subject prototypes (Section 0), in this case *S1* (Table 3), which is added to the situation description.

Figure 5 depicts a screenshot of a mobile device showing the application web-interface while supporting a user to semi-automatically locate him-/herself utilizing geodata dynamically retrieved from GoogleMaps. By providing incomplete knowledge about the current location, for instance the current city, full geospatial datasets, including the latitude and longitude of a location, are retrieved dynamically to enable similarity-based location matchmaking.

Figure 5. Mobile device showing semi-automatic location detection.

Based on the current situation description, SWS are selected which are able to address the situation. Whereas parameters which are not defined by members in a specific CSS require a direct match with a corresponding SWS description, a similarity-based match is computed for parameters which are described in a CSS, e.g. the location or the subject. Hence, distance calculation was utilized to identify similarities between current context parameters – such as *E* and *S1* – and prototypical parameters which had been defined as part of SWS capability descriptions in order to represent the parameters targeted by available SWS. In order to illustrate the representation of prototypical CSS members, the following OCML code defines a location parameter instance representing the geospatial location Brighton, as well as the respective prototypical member (*L3*) in the MSS *L*.

Calculating distances between *E* and targeted locations – represented as prototypical MSS members - led to the identification of the following distances to the three closest matches: (Table 4)

Since not any SWS targets historical interests (*S1*) exclusively – as desired by the user - no direct match between the situation and subjects targeted by available SWS was achieved. However, similarity calculation identified related subject areas, which partially target historical information. Table 5 indicates their vectors and distances to the required subject *S1*.

The subjects *S5*, *S6* and *S7* as well as the locations *L1*, *L2*, and *L3* shown in Table 4 and Table 5 had been described as prototypical members in the MSS (Section 0) during the development of SWS representations targeting certain subjects and locations. By following our alignment from Section 0, this task could be performed by either the Web service provider or any SWS expert who is providing and publishing a semantic representation of available Web services.

As indicated by the Euclidean distances depicted in Tables 4 and 5, the closest matching SWS provides historical and cultural (*S7*) resources for the Brighton (*L3*) area, as these show the lowest distances. Provided these similarities, a user is able to select predefined parameters that best suit his/her specific preferences within the current situation. In that, the use of similarity-based classification enables the gradual refinement of

a situation description and fuzzy matchmaking between real-world situations, and prototypical parameters predefined within a SWS description. For example, the following OCML code defines the partial capability description of a Web service that provides historic and cultural information for the area of Brighton:

In fact, the assumption expression presented above describes that situation description representing the current situation (*has-situation*) consider the location *Brighton* and the subject *S7*.

As a result, in our approach, the actual mobile situation description (i.e. the actual context) is the result of an iterative process that involves several distance calculations to map symbolic representations and real world characteristics. Notice that this process actively involves the end users in providing observables and validating the distance calculations. According to the obtained situation parameters and the selected user goal, the SEE discovers and orchestrates annotated Web services, which show the capabilities to suit the given situation representation. Whereas discovery and orchestration are addressed by existing SWS technology, the context-aware selection of a specific SWS goal representation is addressed through CSS by enabling similarity-based classifications of individual situations as described in the previous sections.

RELATED WORK

Since our work relates to several different but related research areas, we report here related work on (i) Semantic Web Services, (ii) Context-adaptive systems, and (iii) Context-adaptation in mobile environments. Moreover, by comparing our approach with related work in (iii) we describe our contribution to the current state of the art in context-adaptive mobile and ubiquitous computing.

SWS: OWL-S (OWL-S Coalition. 2004) is a comparatively narrow framework and ontology for adding semantics to Web service descriptions. In order to identify problematic aspects of OWL-S and suggest possible enhancements, a contextualized core ontology of services has been described in Mika et al. (2004). Such an ontology is based on DOLCE (Gangemi et al., 2002) and its specific module D&S (Gangemi, Mika, 2003). Even though we followed a similar approach, we adopt WSMO (WSMO Working Group, 2004) instead of OWL-

```

S as reference ontology for SWS. Moreover, the aim of our resulting ontology is not proposing changes to WSMO, but creating domain-specific models which incorporate WSMO-based SWS representations.

Context-adaptive systems: in Bouquet et al. (2003) the authors define contexts as the local models that encode a party's view of a domain. They distinguish contexts from ontologies, since the latter are shared models of some domain that encode a view which is common to a set of different parties. Contexts are best used in those applications where the core problem is the use and management of local and autonomous representations with a need for a lack of centralized control. For example, the notion of contexts is used in some applications of distributed knowledge management Bonifacio et al. (2003), pervasive computing environments (Chen, Finin & Joshi, 2003) and peer-to-peer applications (Serafini et al., 2003). According to the definition introduced in Bouquet et al. (2003), we propose a novel use of contexts. The local models encode party's view of SWS-based process descriptions.

Context-adaptation in mobile environments: Weissenberg et al. (2006) adopt an approach to context-adaptation in mobile settings which shows some similarities to ours: given a set of context parameters – based on sensor data – first a context is identified and then a matching situation. However, they rely on manually predefined axioms which enable such a reasoning compared to the automatic detection as proposed in this paper. Korpipaa et al. (2003) propose a related framework but firstly, require client-side applications to be installed and, secondly, relies on Bayesian reasoning for matching between measured lower-level contexts and higher-level context abstractions represented within an ontology. Hence, as a major lack, it is required to provide information about contexts and their relations within a Bayesian Network in order to perform the proposed reasoning. Gu, Wang, Pung & Zang (2004) propose a context-aware middleware which also distinguishes between lower-level and higher-level contexts. However, there is no mechanism to automatically identify relationships between certain contexts or context parameters. The same criticism applies to the approaches to a semantic representation of user contexts described in Toivinen, Kolari & Laako (2003) and Sathish, Pavel & Trossen (2006).

Finally, it can be highlighted, that current approaches to context-adaptation in mobile settings usually rely on the manual representation of mappings between a given set of real-world context data and predefined context representations. Since this approach is costly and time-consuming, our approach could contribute there significantly by providing a similarity-based and rather fuzzy method for automatically identifying appropriate symbolic context representations given a set of detected context parameters.

CONCLUSION

In this paper, we proposed an approach to support fuzzy, similarity-based matchmaking between real-world situation parameters in mobile settings and predefined semantic situation descriptions by incorporating semantic context information on a conceptual level into symbolic SWS descriptions based on Conceptual Situation Spaces. Given a particular mobile situation, defined by parameters such as the location and device of the user, the most appropriate resources, whether data or services, are discovered based on the semantic similarity, calculated in terms of the Euclidean distance, between the real-world situation and predefined resource descriptions as part of SWS representations. Even though we refer to the SWS framework WSMO in this paper, we would like to highlight, that our approach could be applied to other SWS reference ontologies such as OWL-S (OWL-S Coalition. 2004). Consequently, by aligning CSS to established SWS technologies, the expressiveness of symbolic SWS standards is extended with context information on a conceptual level described in terms of natural quality dimensions to enable fuzzy context-aware delivery of information resources at runtime. Whereas current SWS frameworks address the allocation of distributed services for a given (semantically) well-described task, Mobile Situation Spaces particularly address the similarity-based discovery of the most appropriate SWS task representation for a given situation. To prove the feasibility of our approach, a proof-of-concept prototype application was presented, which applies the MSS to enable context-adaptive resource discovery in a mobile setting.

However, although our approach applies CS to solve SWS-related issues such as the symbol grounding problem, several criticisms still have to be taken into account. Whereas defining situational contexts, respectively members within a given MSS, appears to be a straightforward process of assigning specific values to each quality dimension, the definition of the MSS itself is not trivial at all and strongly dependent on individual perspectives and subjective appraisals. Whereas the semantics of an object are grounded to metrics in geometrical vector spaces within a MSS, the quality dimensions itself are subject to ones perspective and interpretation what may lead to ambiguity issues. With regard to this, MSS do not appear to solve the symbol grounding issue but to shift it from the process of describing instances to the definition of a MSS. Moreover, distinct semantic interpretations and conceptual groundings of each dimension may be applied by different individuals. Apart from that, whereas the size and resolution of a MSS is indefinite, defining a reasonable space for a specific domain and purpose may become a challenging task. Nevertheless, distance calculation as major contribution of the MSS approach, not only makes sense for quantifiable parameters but also relies on the fact, that parameters are described in the same geometrical space.

Consequently, CS-based approaches, such as MSS, may be perceived as step forward but do not fully solve the issues related to symbolic Semantic Web (Services)-based knowledge representations. Hence, future work has to deal with the aforementioned issues. For instance, we foresee to enable adjustment of prominence values to quality dimensions of a specific space to be accomplished by a user him/herself, in order to most appropriately suit his/her specific priorities and preferences regarding the resource allocation process, since the prioritization of dimensions is a highly individual and subjective process. Nevertheless, further research will be concerned with the application of our approach to further domain-specific situation settings.

Chapter 7.3
Uncertainty Representation and Reasoning in the Semantic Web

ABSTRACT

This chapter is about uncertainty representation and reasoning for the Semantic Web (SW). We address the importance, key issues, state-of-the-art approaches, and current efforts of both the academic and business communities in their search for a practical, standard way of representing and reasoning with incomplete information in the Semantic Web. The focus is on why uncertainty representation and reasoning are necessary, its importance to the SW vision, and the major issues and obstacles to addressing uncertainty in a principled and standardized way. Although some would argue that uncertainty belongs in the "rule layer" of the SW, we concentrate especially on uncertain extensions of ontology languages for the Semantic Web.

DOI: 10.4018/978-1-60566-112-4.ch013

WHY CARE ABOUT UNCERTAINTY?

After some years of SW research, the subject remains rife with controversy, and there is still some disagreement on how uncertainty should be handled in SW applications. Thus, it is no surprise that little was said on the subject in previous chapters of this book. A major reason for the present state of affairs is that the most popular technologies employed in SW applications are rooted in traditional knowledge representation formalisms that have historically ignored uncertainty. The most compelling examples are Frame Systems (Minsky, 1975), and Description Logics, which evolved from the so-called "Structured Inheritance Networks" (Brachman, 1977), and form the logical basis for the ontology language OWL.

The spotlight is not on the *status quo*, but on what the future holds. To answer this question, we begin with a comprehensive analysis of the major challenges to be faced by the SW community, including what kinds of interactions, scenarios, demands, and obstacles must be addressed to make the SW promises a reality. Next, we assess whether protocols that rely only on complete, deterministic information will suffice to address these challenges. Although much progress has been made by tackling problems in which uncertainty is inessential or can be circumvented, addressing the full range of challenges inherent in the Semantic Web vision will require optimal use of *all* available information. In this Chapter, we argue that a principled framework for representing and reasoning with incomplete information is necessary to realizing the SW vision. Because uncertainty is a ubiquitous aspect of most real-world problems, any representation scheme intended to model real-world entities, properties and processes must be able to cope with uncertain phenomena. Current SW technologies' inability to represent and reason about uncertainty in a sound and principled manner raises an unnecessary barrier to the development of new, powerful features for general knowledge application, a limitation that threatens to derail the original vision for the Semantic Web as a whole. In other words, we argue that realizing the SW as envisioned by Tim Berners-Lee (Berners-Lee & Fischetti, 2000) requires a principled framework for representing and reasoning with uncertainty.

The Semantic Web envisions effortless cooperation between humans and computers, seamless interoperability and information exchange among web applications, and rapid and accurate identification and invocation of appropriate Web services. While considerable progress has been achieved toward realization of the Semantic Web vision, it is increasingly apparent that a sound and principled technology for handling uncertainty is an important requirement for continued progress. Uncertainty is an unavoidable factor in knowledge interchange and application interoperability. Different applications have different ontologies, different semantics, and different knowledge and data stores. Legacy applications are usually only partially documented and may rely on tacit usage conventions that even proficient users do not fully understand or appreciate. Furthermore, data that is exchanged in the context of the semantic web is often incomplete, inconsistent, and inaccurate. This suggests that recent work in the application of probability, fuzzy logic, and decision theory to complex, open-world problems could be of vital importance to the success of the Semantic Web. Incorporating these new technologies into languages, protocols, and specifications for the Semantic Web is fundamental to realizing the Semantic Web vision.

Typical Problems Needing Uncertainty Representation and Reasoning. The following web-relevant reasoning challenges illustrate the kinds of problems for which reasoning under uncertainty is important.

- Information extracted from large information networks such as the World Wide Web is typically incomplete. The ability to exploit partial information is useful for identifying sources of service or information. For example, the fact that an online service deals with greeting cards may be evidence that it also sells stationery. It is clear that search tools capable of utilizing probabilistic knowledge could increase search effectiveness.
- Much information on the World Wide Web is likely to be uncertain. Common examples include weather forecasts and gambling odds. A canonical method for representing and integrating such information and the uncertainty associated with it is necessary for communicating such information in a seamless fashion.
- Web information is also often incorrect or only partially correct, raising issues related to trust or credibility. Uncertainty representation and reasoning helps to resolve

tensions amongst information sources for purposes of approximating appropriately.

- The Semantic Web will require numerous distinct but conceptually overlapping ontologies to co-exist and interoperate. Ontology mapping will benefit from the ability to represent and reason with information about partial overlap, such as likelihoods of membership in Class A of Ontology 1 given membership in Class B of Ontology 2.

Section 5 below discusses some use cases, based on the work of the W3C Uncertainty Reasoning for the World Wide Web Incubator Group (URW3-XG). These use cases exhibit the above characteristics, and are representative of the kinds of challenges that the SW must address. Despite the potential that a principled framework for representing uncertainty would have in contributing to the development of robust SW solutions, for historical reasons, research on the Semantic Web started with little support for representing and reasoning in the presence of uncertain, incomplete knowledge. As interest in and application of SW technology grows, there is increasing recognition of the need for uncertain reasoning technology, and increasing discussion of the most appropriate ways to address this need.

Should Ontologies Represent Uncertainty? A major impediment to widespread adoption of technologies for representing and reasoning with incomplete information is the dominance of the classical logic paradigm in the field of ontological engineering. There is a plethora of definitions of the term ontology in the field of information systems. Among these, a common underlying assumption is that classical logic would provide the formal foundation for knowledge representation and reasoning. Until recently, theory and methods for representing and reasoning with uncertain and incomplete knowledge have been neglected almost entirely. However, as research on knowledge engineering and applications of ontologies matures, the ubiquity and importance of uncertainty across a wide array of application areas has generated consumer demand for ontology formalisms that can capture uncertainty. Although recognition of the need for uncertainty reasoning is growing, there is disagreement about its appropriate place in the Semantic Web architecture. We have argued elsewhere (e.g., Costa, 2005; Costa and Laskey, 2006), that there is a need to represent declarative knowledge about likelihood in domain ontologies. In environments in which noisy and incomplete information is the rule, likelihood information is a key aspect of domain knowledge. Furthermore, much of the key semantic content needed to enable interoperability involves information about plausibility. For this reason, we have argued, knowledge about likelihoods should be included in formal domain ontologies.

This viewpoint is not universal. A counterargument to our position is that probability is inherently epistemic, whereas formal ontology should represent phenomena as they exist in the world. Carried to its extreme, however, this philosophical stance would preclude the use of virtually every ontology that has yet been developed. To explore this idea further, we note that if computational ontologies had existed in the 17th century, Becher and his followers might well have developed an ontology of phlogiston. We may chuckle now at their naïveté, but who among our 17th century predecessors had the foresight to judge which of the many scientific theories then in circulation would stand the test of time? Researchers in medicine, biology, defense, astronomy, and other communities have developed a plethora of domain ontologies. It is virtually certain that at least some aspects of some of these ontologies will, as human knowledge progresses, turn out in retrospect to be as well founded as the theory of phlogiston. Shall we outlaw use of all these ontologies until the day we can prove they contain only that which is ontological, and nothing that is mere epistemology? Moreover, many aspects of our common, shared knowledge of these domains are inherently probabilistic. Well-established statistical regularities are a key element of expert reasoning. A principled means of representing these probabilistic aspects of domain knowledge is needed to facilitate interoperability and knowledge sharing.

Similar questions arise with the representation of vagueness. Fuzzy logic has been applied extensively to problems of reasoning with imprecisely defined terms. For example, fuzzy reasoning might be applied to retrieve and sort responses to a query for "inexpensive" patio furniture. A fuzzy reasoner would assign each furniture set a degree of membership in the fuzzy set "inexpensive," and would sort the retrieved sets by their membership in the fuzzy set. There is an analogous question of whether it is legitimate to extend ontology formalisms to allow representation of fuzzy membership values, or whether fuzziness is inherently epistemological and does not belong in an ontology.

There is a valid, important, and as yet unresolved philosophical clash between those who believe that we live in a deterministic world in which uncertainty is entirely epistemic, and those who believe the world includes phenomena that are ontologically stochastic and/or imprecise and should be represented as such. From an engineering standpoint, we cannot wait for the debate to be resolved before we move forward with building and using ontologies.

Although our ultimate scientific objective is to seek the truth about reality as it is, this ultimate objective is unattainable in the lifetime of any human. Therefore, no "perfect ontology of all things" is reachable, regardless of one's philosophical view on uncertainty. Nevertheless, from a pragmatic perspective, it is necessary and desirable to do the best we can with the knowledge we have, even if this causes the ontology to be under-specified due to incomplete information. Formal ontology provides a useful means of communicating domain knowledge in a precise and shareable manner, and of extending and revising our descriptions as human knowledge accrues. Accepting only complete knowledge would leave us with too little information to solve most of the interesting problems that ontologies are capable of addressing.

Not surprisingly, as ontology engineering research has achieved a greater level of maturity, the need for uncertainty representation and reasoning for the Semantic Web has become more and more clear. Correspondingly, interest is increasing in extending traditional ontology formalisms to include standard mechanisms for representing and reasoning with uncertainty. Whether the ultimate consensus is that ontology formalisms should be capable of representing information about uncertainty, or that ontologies should represent the space of possibilities and that information about uncertainty should be conveyed in a different semantic layer, principled means of representing and reasoning with uncertainty are increasingly seen as necessary.

***Uncertainty in Rule Languages*.** A related stream of research has focused on augmenting SW rule languages to handle uncertainty (Damásio *et al.*, 2006; Lukasiewicz, 2005, 2006; Lukasiewicz & Straccia, 2007). Although there is as yet no standard rule language for the Semantic Web, the W3C's Rule Interchange Format (RIF) Working Group has recently released working draft documents specifying use cases, requirements, and a core design for a format that allows rules to be translated between rules languages[a]. The use cases and requirements document does not mention uncertainty, but the core design mentions the need to translate between rule languages that handle uncertainty, and makes brief mention of syntactic and semantic implications of the need to treat uncertainty. This brief treatment is far from sufficient to address the full range of issues that need to be addressed to achieve semantic interoperability between systems that express and reason with uncertainty. For space reasons, we do not address rule language research in detail in this chapter. We note, however, that augmenting ontologies to express uncertainty generates a requirement to augment rule languages to take advantage of the information expressed in uncertainty-enhanced ontologies.

Towards a Pragmatic View. Apart from the historical and philosophical issues, as research on SW leaves the conceptual level and reaches a level of maturity in which the actual challenges are better understood, realization has grown that many SW applications require a principled means for representing uncertainty and performing plausible reasoning with incomplete data. As the interest in uncertainty representation techniques grows, the focus of SW shifts from philosophical issues toward "down to earth" engineering issues. Important challenges are to identify the kinds of information management problems that would benefit most from mechanisms for reasoning with uncertainty, to assess the scalability of uncertainty representation approaches, to evaluate the suitability of different forms of representation and reasoning to solve specific use cases, and others.

This pragmatic, focused view has pushed researchers from many different domains of knowledge into an appreciation of the need for a forum to discuss the ways in which uncertainty reasoning can contribute to addressing their respective challenges, and to evaluate the strengths and weaknesses of different approaches to representing and reasoning under uncertainty. Although uncertainty-related papers were sometimes presented in other venues, the first forum explicitly geared towards answering the above issues was the workshop on Uncertainty Representation for the Semantic Web (URSW workshop), held in conjunction with the Fourth International Semantic Web Conference (ISWC 2005). The intention of the URSW workshop was to provide an open forum to all forms of uncertainty representation and reasoning, without being prejudicial in favor of any particular approach. At the second workshop (URSW 2006), a consensus was reached that the most important tasks were (1) to develop a set of use cases for uncertainty in the SW; and (2) to assess how each approach (or combination of approaches) would address appropriate challenges set out in the use cases. In the end, a much improved understanding of those issues would led to identification of best practices involving uncertainty reasoning in the SW.

The strong interest in the URSW and similar venues prompted the W3C to create, in March 2007, the Uncertainty Reasoning for the World Wide Web Incubator Group (URW3 XG), with the objective of better defining the challenge of working with incomplete knowledge. The URW3 adopted the same "approach-independent" stance as the URSW, with an initial focus on the problem itself rather than a particular approach to solving it. At the time of this writing, the URW3 is actively pursuing its development of use cases, and planning for a third URSW is underway. The next two sections present a brief view of the major approaches for uncertainty in the SW being discussed in fora such as the URW3 and URSW.

PROBABILISTIC APPROACHES TO UNCERTAINTY IN THE SEMANTIC WEB

Bayesian probability provides a mathematically sound representation language and formal calculus for rational degrees of belief, which gives different agents the freedom to have different beliefs about a given hypothesis. This provides a compelling framework for representing uncertain, incomplete knowledge that can come from diverse agents. Not surprisingly, there are many distinct approaches using Bayesian probability for the Semantic Web.

Bayesian knowledge representation and reasoning systems have their formal basis in the axioms of probability theory (e.g., Ramsey, 1931; Kolmogorov, 1960/1933). Probability theory allows propositions to be assigned truth-values in the range from zero, meaning certain falsehood, to one, meaning certain truth. Values intermediate

$$P(B|A) = \frac{P(A|B)P(B)}{P(B)}$$

between zero and one reflect degrees of likelihood of a proposition that may be either true or false. *Bayes Rule*, a theorem that can be derived from the axioms of probability theory, provides a method of updating the probability of a proposition when information is acquired about a related proposition. The standard format of Bayes rule is:

On the right side of the formula, $P(A)$ is called the prior probability of A, and represents our belief in event A before obtaining information on event B. Likewise, $P(B)$ is called the prior probability of B. There is also $P(A|B)$, which is the likelihood of event A given that event B has happened. On the left side of the formula there is $P(B|A)$, which is the posterior probability of B, and represents our new belief in event B after applying Bayes rule with the information collected from event A. Bayes rule provides the formal basis for the active and rapidly evolving field of Bayesian probability and statistics. In the Bayesian view, inference is a problem of belief dynamics. Bayes rule provides a principled methodology for belief change in the light of new information.

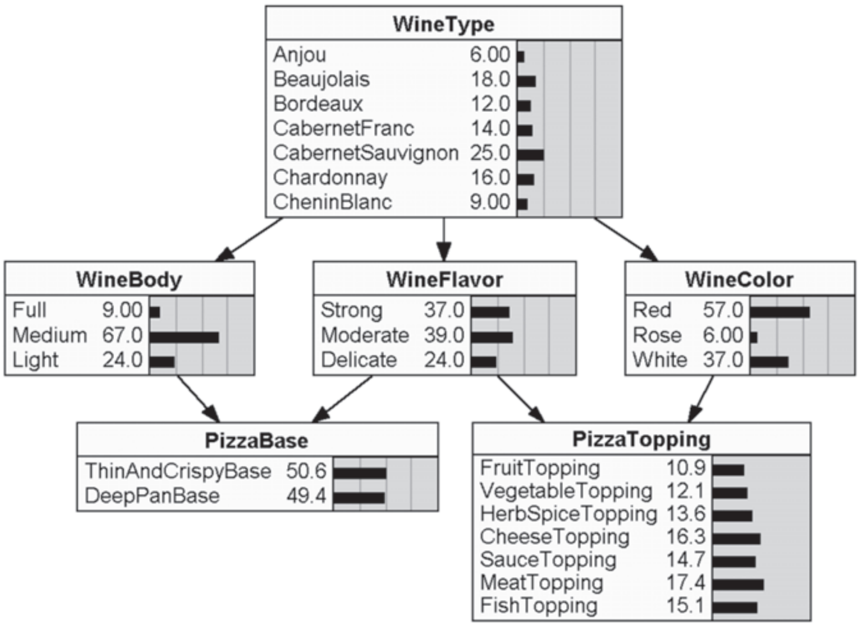
Bayesian Networks (BNs). BNs provide a means of parsimoniously expressing joint probability distributions over many interrelated hypotheses. A Bayesian network consists of a directed acyclic graph (DAG) and a set of local distributions. Each node in the graph represents a random variable. A random variable denotes an attribute, feature, or set of hypotheses about which we may be uncertain. Each random variable has a set of mutually exclusive and collectively exhaustive possible values. That is, exactly one of the possible values is or will be the actual value, and we are uncertain about which one it is. The graph represents direct qualitative dependence relationships; the local distributions represent quantitative information about the strength of those dependencies. The graph and the local distributions together represent a joint probability distribution over the random variables denoted by the nodes of the graph.

Bayesian networks have been successfully applied to create consistent probabilistic representations of uncertain knowledge in diverse fields. Heckerman *et al.* (1995) provide a detailed list of recent applications of Bayesian Networks. The prospective reader will also find comprehensive coverage of Bayesian Networks in a large and growing literature on this subject, such as Pearl (1988), Neapolitan (1990, 2003), and others. Figure 1 shows an example of a BN representing part of a highly simplified ontology for wines and pizzas.

In this toy example[b], we assume that domain knowledge about gastronomy was gathered from sources such as statistical data collected among restaurants and expertise from sommeliers and pizzaiolos. Moreover, the resulting ontology also considered incomplete knowledge to establish a probability distribution among features of the pizzas ordered by customers (i.e. type of base and topping) and characteristics of the wines ordered to accompany the pizzas.

Consider a customer who enters a restaurant and requests a pizza with cheese topping and a thin and crispy base. Using the probability distribution stored in the BN of Figure 1, the waiter can apply Bayes rule to infer the best type of wine to offer the customer given his pizza preferences the body of statistical and expert information previously linking features of pizza to wines. Such computation would be difficult when there are very many features. Bayesian networks provide a parsimonious way to express the joint distribution and a computationally efficient way to implement Bayes rule. This inferential process is shown in Figure 2, where evidence (i.e., the customer's order) was entered in the BN and its result points to Beaujolais as the most likely wine the customer would order, followed by Cabernet Sauvignon, and so on.

Figure 1. A BN for pizzas and wines

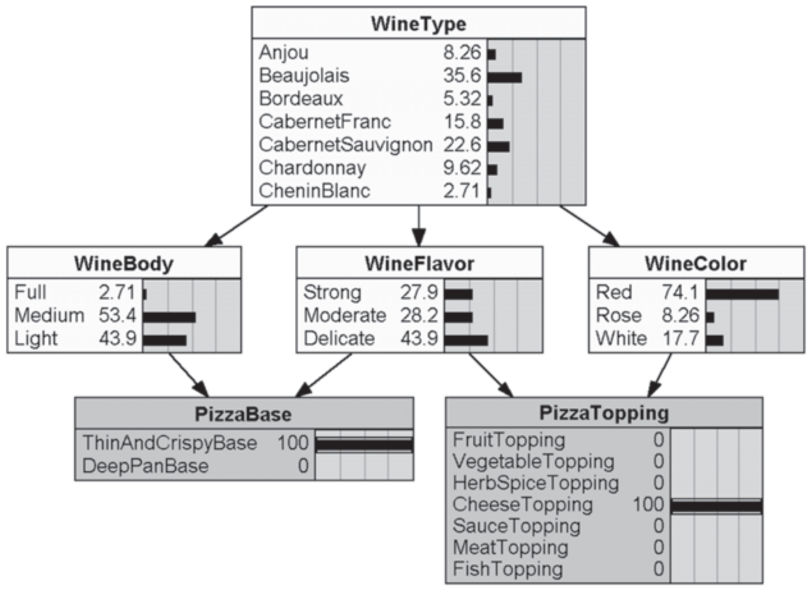


Although this is just a toy example, it is useful to show how incomplete information about a domain can be used to improve decisions. In an ontology without uncertainty, there would not be enough information for a logical reasoner to infer a good choice of wine to offer the customer, and the decision would have to be made without optimal use of all the information available.

As Bayesian networks have grown in popularity, their shortcomings in expressiveness for many real-world applications have become increasingly apparent. More specifically, Bayesian Networks assume a simple attribute-value representation – that is, each problem instance involves reasoning about the same fixed number of attributes, with only the evidence values changing from problem instance to problem instance. In the pizza and wine example, the PizzaTopping random variable conveys general information about the class of pizza toppings (i.e., types of toppings for a given pizza and how it is related to preferences over wine flavor and color), but the BN in Figures 1 and 2 is valid for pizzas with only one topping. To deal with more elaborate pizzas, it is necessary to build specific BNs for each configuration, each one with a distinct probability distribution. Figure 3 depicts a BN for a 3- topping pizza with a specific customer preference displayed. Also, the information conveyed by the BNs (i.e., for 1-topping, 2-toppings, etc.) relates to the class of pizza toppings, and not to specific instances of those classes. Therefore, the BN in Figure 3 cannot be used for a situation in which the costumer asks for two 3-topping pizzas. This type of representation is inadequate for many problems of practical importance. Similarly, these BNs cannot be used to reason about a situation in which a customer orders several bottles of wine that may be of different varieties. Many domains require reasoning about varying numbers of related entities of different types, where the numbers, types, and relationships among entities usually cannot be specified in advance and may have uncertainty in their own definitions.

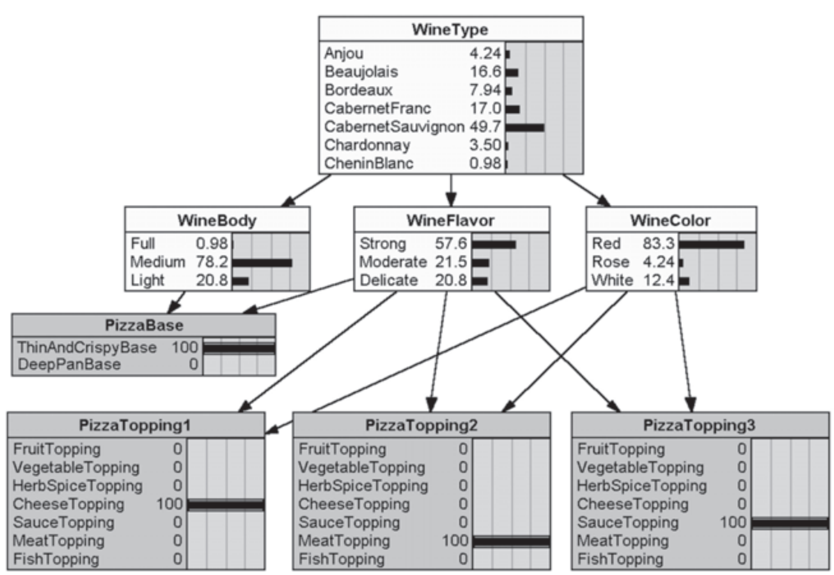
In spite of their limitations, BNs have been used in specific applications for the SW where

Figure 2. BN after entering evidence



the limitations on expressivity can be overcome by clever knowledge engineering workarounds. One example is BayesOWL (Ding and Peng, 2004; Ding, 2005), which augments OWL semantics to allow probabilistic information to be represented via additional markups. The result is a probabilistic annotated ontology that could then be translated to a Bayesian network. Such a translation is based on a set of translation rules that rely on the probabilistic information attached to individual concepts and properties within the annotated ontology. After successfully achieving

Figure 3. A BN for the 3-topping pizza configuration with evidence



the translation, the resulting Bayesian network will be associated with a joint probability distribution over the application domain. Although a full translation of an ontology to a standard BN is impossible given the limitations of the latter in terms of expressivity, the scheme can be successfully used to tackle specific problems involving uncertainty.

Also focusing on Bayesian extensions geared towards the Semantic Web is the work of Gu *et al*. (2004), which takes an approach similar to that of BayesOWL. A related effort is the set of RDF extensions being developed by Yoshio Fukushige (2004). Generally speaking, SW approaches that rely on BNs will have to compensate for their lack of expressiveness by specializing in a specific type of problem, such as the BN-focused approaches for solving the ontology mapping problem (e.g., Mitra *et al.*, 2004; and Pan *et al.*, 2005; Peng *et al.*, 2007).

Probabilistic Extensions to Description Logics. Most of the probabilistic extensions aimed at the ontology engineering domain are based on description logics (DLs), which Baader and Nutt (2003, page 47) define as a family of knowledge representation formalisms that represent the knowledge of an application domain (the "world") by first defining the relevant concepts and roles of the domain (its terminology), which represent classes of objects/individuals and binary relations between such classes, respectively, and then using these concepts and roles to specify properties of objects/individuals occurring in the domain (the world description).

Description logics divide a knowledge base into two components: a terminological box, or T-Box, and the assertional box, or A-Box. The first introduces the terminology (i.e., the vocabulary) of an application domain, while the latter contains assertions about instances of the concepts defined in the T-Box. Description logics are a subset of first-order logic (FOL) that provide a very good combination of decidability and expressiveness. In fact, an important desired property of description logics is the decidability of their reasoning tasks. Description logics are also the basis of the web ontology language OWL, whose sublanguages OWL Lite and OWL DL correspond to the expressive description logics *SHIF*(**D**) and *SHOIN*(**D**), respectively.

There are several probabilistic extensions of description logics in the literature, which can be classified according to the generalized description logics, the supported forms of probabilistic knowledge, and the underlying probabilistic reasoning formalism.

Heinsohn (1994) presents a probabilistic extension of the description logic *ALC* (a member of the *AL*-languages (Schmidt-Schauß & Smolka, 1991) obtained by including the full existential quantification and the union constructors to the basic *AL* (attributive language)), which allows representation of terminological probabilistic knowledge about concepts and roles, and which is essentially based on probabilistic reasoning in probabilistic logics. Heinsohn, however, does not allow for assertional knowledge about concept and role instances. Jaeger (1994) proposes another probabilistic extension of the description logic *ALC*, which allows for terminological and assertional probabilistic knowledge about concepts and roles and about concept instances, respectively, but does not support assertional probabilistic knowledge about role instances (but he mentions a possible extension in this direction). The uncertain reasoning formalism in (Jaeger, 1994) is essentially based on probabilistic reasoning in probabilistic logics, as the one in (Heinsohn, 1994), but coupled with cross-entropy minimization to combine terminological probabilistic knowledge with assertional probabilistic knowledge. Jaeger's recent work (2006) focuses on interpreting probabilistic concept subsumption and probabilistic role quantification through statistical sampling distributions, and develops a probabilistic version of the guarded fragment of first-order logic.

The work by Koller *et al.* (1997) gives a probabilistic generalization of the CLASSIC description logic, called P-CLASSIC. In short, each probabilistic component is associated with a set P of p-classes, and each p-class C in set P is represented using a Bayesian network. Like Heinsohn's work (1994), the work by Koller *et al.* (1997) allows for terminological probabilistic knowledge about concepts and roles, but does not support assertional probabilistic knowledge about instances of concepts and roles. However, differently from (Heinsohn, 1994), it is based on inference in Bayesian networks as underlying probabilistic reasoning formalism. Closely related work by Yelland (2000) combines a restricted description logic close to *FL* with Bayesian networks. It also allows for terminological probabilistic knowledge about concepts and roles, but does not support assertional knowledge about instances of concepts and roles.

Another DL with a probabilistic extension is *SHOQ*(**D**) (Horrocks & Sattler, 2001). *SHOQ*(**D**) is the basis of DAML+OIL (Horrocks, 2002), the language that came from merging two ontology languages being developed in the US (DAML) and Europe (OIL) and has been superseded by OWL. Its probabilistic extension is called P-*SHOQ*(**D**) (Giugno & Lukasiewicz, 2002) (see also (Lukasiewicz, 2008)) and allows for expressing both terminological probabilistic knowledge about concepts and roles, as well as assertional probabilistic knowledge about instances of concepts and roles. P-*SHOQ*(**D**) is based on probabilistic lexicographic entailment from probabilistic default reasoning (Lukasiewicz, 2002) as underlying probabilistic reasoning formalism, which treats terminological and assertional probabilistic knowledge in a semantically very appealing way as probabilistic knowledge about random and concrete instances, respectively.

Description logics are highly effective and efficient for the classification and subsump-tion problems that they were designed to address. However, their ability to represent and reason about other commonly occurring kinds of knowledge is limited. One restrictive aspect of DL languages is their limited ability to represent constraints on the instances that can participate in a relationship. As an example, a probabilistic Description Logics version of the toy example in Figures 1 to 3 would allow us to instantiate (say) three pizzas. However, suppose we want to express that for a given pizza to be compatible with another pizza in a specific type of situation (e.g., a given mixture of toppings for distinct pizzas), it is mandatory that the two individuals of class pizza involved in the situation are not the same. In DLs, making sure that the two instances of class pizza are different in a specific situation is only possible if we actually instantiate/specify the tangible individuals involved in that situation. Indeed, stating that two "fillers" (i.e., the actual individuals of class Pizza that will "fill the spaces" of concept pizza in our statement) are not equal without specifying their respective values would require constructs such as *negation* and *equality role-value-maps*, which cannot be expressed in description logics. While equality and role-value-maps provide additional useful means to specify structural properties of concepts, their inclusion makes the logic undecidable (Calvanese & De Giacomo, page 223).

First-Order Probabilistic Approaches. In recent years, a number of languages have appeared that extend the expressiveness of probabilistic graphical models in various ways. This trend reflects the need for probabilistic tools with more representational power to meet the demands of real world problems, and goes to the encounter of the needs for Semantic Web representational schemes compatible with incomplete, uncertain knowledge. A clear candidate logic to fulfill this requirement for extended expressivity is first-order logic (FOL), which according to Sowa (2000, page 41) "has enough expressive power to define all of mathematics, every digital computer that has ever been built, and the semantics of every version of logic, including itself."

FOL was invented independently by Frege and Pierce in the late nineteenth century (Frege, 1879/1967; Pierce, 1898) and is by far the most commonly used, studied, and implemented logical system. A theory in first-order logic assigns definite truth-values only to sentences that have the same truth-value (either true or false) in all interpretations of the theory. The most that can be said about any other sentence is that its truth-value is indeterminate. A logical system is *complete* if all valid sentences can be proven and *negation complete* if for every sentence, either the sentence or its negation can be proven. Kurt Gödel proved both that first-order logic is complete, and that no consistent logical system strong enough to axiomatize arithmetic can be negation complete (cf. Stoll, 1963; Enderton, 2001). However, systems based on classical first-order logic lack a theoretically principled, widely accepted, logically coherent methodology for reasoning under uncertainty. Below are some of the approaches addressing this issue.

Object-Oriented Bayesian Networks (Koller & Pfeffer, 1997; Bangsø & Wuillemin, 2000; Langseth & Nielsen, 2003) represent entities as instances of object classes with class-specific attributes and probability distributions. Probabilistic Relational Models (PRM) (Pfeffer *et al.*, 1999; Getoor *et al.*, 2000; Getoor *et al.*, 2001; Pfeffer, 2001) integrate the relational data model (Codd, 1970) and Bayesian networks. PRMs extend standard Bayesian Networks to handle multiple entity types and relationships among them, providing a consistent representation for probabilities over a relational database. PRMs cannot express arbitrary quantified first-order sentences and do not support recursion. Although PRMs augmented with DBNs can support limited forms of recursion, they still do not support general recursive definitions. Jaeger (1997) extends relational probabilistic models to allow recursion, but it is limited to finitely many random variables. Plates (Buntine, 1994; Gilks *et al.*, 1994; Spiegelhalter *et al.*, 1996) represent parameterized statistical models as complex Bayesian networks with repeated components.

DAPER (Heckerman *et al.*, 2004) combines the entity-relational model with DAG models to express probabilistic knowledge about structured entities and their relationships. Any model constructed in Plates or PRM can be represented by DAPER. Thus, DAPER is a unifying language for expressing relational probabilistic knowledge. DAPER expresses probabilistic models over finite databases, and cannot represent arbitrary first-order sentences involving quantifiers. Therefore, like other languages discussed above, DAPER does not achieve full first-order representational power.

MEBN (Laskey and Mahoney, 1997; Laskey and Costa, 2005; Laskey, 2007) represents the world as consisting of entities that have attributes and are related to other entities. Knowledge about the attributes of entities and their relationships to each other is represented as a collection of MEBN fragments (MFrags) organized into MEBN Theories (MTheories). An MFrag represents a conditional probability distribution for instances of its resident random variables given their parents in the fragment graph and the context nodes. An MTheory is a set of MFrags that collectively satisfies consistency constraints ensuring the existence of a unique joint probability distribution over instances of the random variables represented in each of the MFrags within the set. MEBN semantics integrates the standard model-theoretic semantics of classical first-order logic with random variables as formalized in mathematical statistics.

Although the above approaches are promising where applicable, a workable solution for the Semantic Web requires a general-purpose formalism that gives ontology designers a range of options to balance tractability against expressiveness. Current research on SW formalisms using first-order probabilistic logics is still in its infancy, and generally lack a complete set of publicly available tools. Examples include PR-OWL (Costa, 2005), which is an upper ontology for building probabilistic ontologies based on MEBN logic[c], and KEEPER (Pool and Aiken, 2005), an OWL-based interface for the relational probabilistic toolset Quiddity*Suite, developed by IET, Inc.

Their constructs are similar in spirit and provide an expressive method for representing uncertainty in OWL ontologies. Costa (2005) gives a definition for Probabilistic Ontologies, develops rules for constructing PR-OWL ontologies in a manner that can be translated into Quiddity*Suite, and describes how to perform the translation.

As an illustration of the expressiveness of a first-order probabilistic logic, Figure 4 presents a graphical depiction of the MFrags for the wine and pizza toy example.[d] It conveys both the structural relationships (implied by the arcs) among the nodes and the numerical probabilities (embedded in the probability distributions and not depicted in the figure). The MFrags depicted in Figure 4 form a consistent set that allows to reason probabilistically about a domain and can be stored in an OWL file using the classes and properties defined in the PR-OWL upper ontology. The MFrags can be used to instantiate situation specific Bayesian networks to answer queries about the domain of application being modeled. In other words, a PR-OWL probabilistic ontology consists of both deterministic and probabilistic information about the domain of discussion (e.g., wines and pizzas), stored in an OWL file that can be used for answering specific queries for any configuration of the instances given the evidence at hand.

In particular, the toy ontology of Figure 4 can be applied to reason about situations involving any number of pizzas with any number of toppings on each, accompanied by any number of bottles of wine, and including any possible interactions among specific instances of those. Figure 5 illustrates this concept, depicting a situation in which evidence a customer has ordered one thin and crispy pizza with three toppings (cheese, meat, and sauce) and is planning to order one bottle of wine. The BN represents the response to a request to suggest a good wine to go with the pizzas.

In MEBN syntax[e], the knowledge base is augmented by an instance of pizza (!P0), three instances of topping types (!T0, !T1, !T2), and an instance of wine (!W0). To answer the query on the wine suggestion, a probabilistic reasoner will use the evidence available to build a Situation Specific Bayesian Network (SSBN). This example was constructed to yield the same BN as Figure 3. This illustrates the point that the MFrags in Figure 4 have captured all information that is needed to

Figure 4. MFrags representing the wine and pizza example

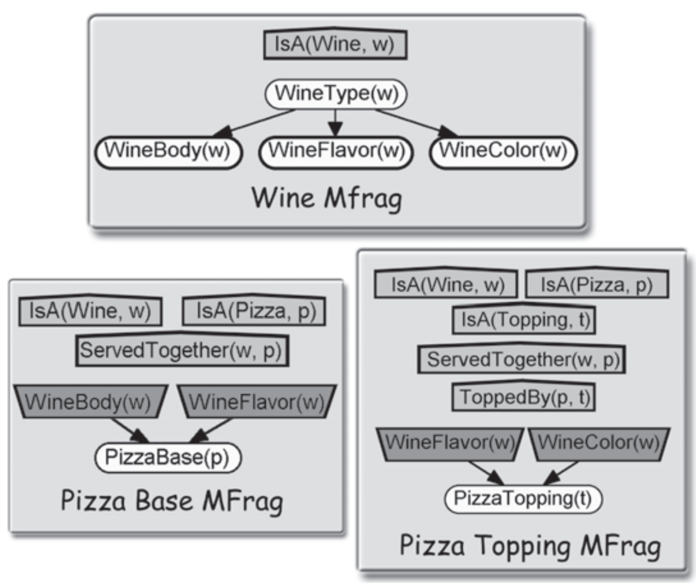


Figure 5. SSBN constructed from the MFrags of Figure 4

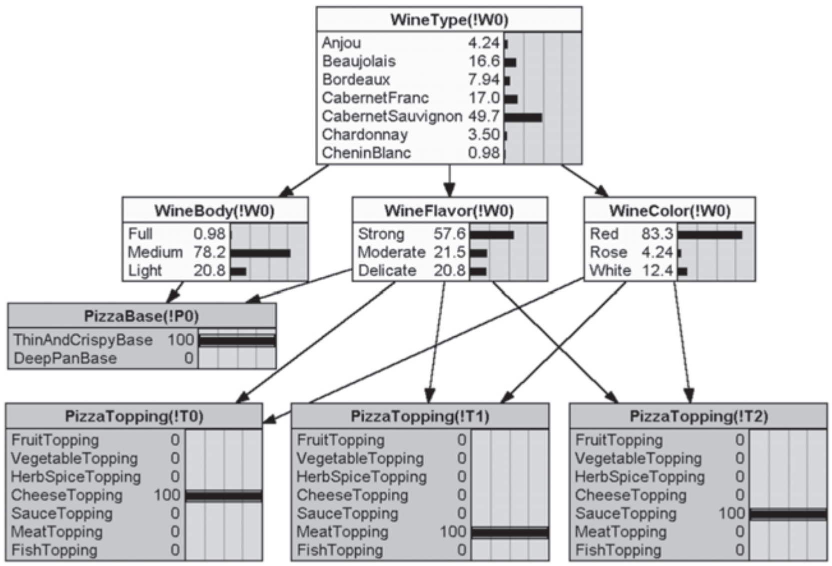


build SSBNs for any specific configuration of pizzas and wines for this toy example.

Clearly, this example is oversimplified, but it suffices to illustrate how PR-OWL can be used to build a probabilistic ontology combining legacy ontologies of pizzas and wines. This example illustrates the use of an expressive probabilistic language to capture knowledge that cannot be expressed with standard Bayesian networks. Probabilistic ontologies are an increasingly important topic in forums devoted to best practices in systems development. Given the nature of the domain knowledge embedded in their systems, system developers in general would profit most from the advantages of being able to convey such knowledge with a principled treatment for uncertainty.

FUZZY FORMALISMS APPLIED TO THE SEMANTIC WEB

In contrast to probabilistic formalisms, which allow for representing and processing degrees of uncertainty about ambiguous pieces of information, fuzzy formalisms allow for representing and processing degrees of truth about vague (or imprecise) pieces of information. The following examples illustrate the difference between degrees of uncertainty and degrees of truth.

Consider the statement "it will rain tomorrow". This statement is *uncertain*, that is, it is either true or false, depending on the weather conditions of tomorrow, but we generally do not have a complete knowledge about whether it will rain tomorrow or not. In probabilistic formalisms, we thus assume a set of possible worlds, each of which is associated with a probability. Intuitively, we are uncertain about which possible world is the right one. In each world, we only allow for binary truth-values, and thus in each world the statement "it will rain tomorrow" is either true or false. This way, we can quantify our ignorance about whether it will rain tomorrow or not. For example, we may say that the probability that it will rain tomorrow is 0.7, which means that the probabilities of all worlds in which it will rain tomorrow sum up to 0.7.

Consider next the statement "John is tall." This statement is *vague*, that is, it is more or less true, depending on the body height of John, but we are unable to say whether this statement is completely true or false due to the involvement of the vague concept "tall," which does not have a precise definition. In fuzzy formalisms, we assume fuzzy interpretations, which directly generalize binary interpretations by mapping elementary vague propositions into a truth value space between false and true. For example, we may say that John is tall with the degree of truth 0.7, which intuitively means that John is relatively tall but not completely tall.

It is also important to point out that vague statements are truth-functional, that is, the degree of truth of a vague complex statement (which is constructed from elementary vague statements via logical operators) can be calculated from the degrees of truth of its constituents, while uncertain complex statements are generally not a function of the degrees of uncertainty of their constituents (Dubois and Prade, 1994).

Vagueness abounds especially in multimedia information processing and retrieval. Another typical application domain for vagueness and thus fuzzy formalisms are natural language interfaces to the Web. Furthermore, fuzzy formalisms have also been successfully applied in ontology mapping, information retrieval, and e-commerce negotiation tasks.

Fuzzy Propositional Logics. Rather than being restricted to a binary truth value among false and true, *vague propositions* may also have a truth value strictly between false and true. One often assumes the unit interval [0, 1] as the set of all possible truth values, where 0 and 1 represent the ordinary binary truth values false and true, respectively. For example, the vague proposition "John is tall" may be more or less true, and it is thus associated with a truth value in [0, 1], depending on the body height of John.

To combine and modify the truth values in [0, 1], one assumes *combination functions*, namely, *conjunction*, *disjunction*, *implication*, and *negation functions*, denoted $\otimes$, $\oplus$, $\triangleright$, and $\ominus$, respectively, which are functions $\otimes, \oplus, \triangleright$: $[0, 1]\times[0, 1] \rightarrow [0, 1]$ and $\ominus$: $[0, 1] \rightarrow [0, 1]$ that generalize the ordinary logical operators $\wedge$, $\vee$, $\rightarrow$, and $\neg$, respectively, to the set of truth values [0, 1]. As usual, we assume that the combination functions have some natural algebraic properties, namely, the properties shown in Tables 1 and 2. Note that in Table 1, Tautology and Contradiction follow from Identity, Commutativity, and Monotonicity. Note also that conjunction and disjunction functions (with the properties shown in Table 1) are also called *triangular norms* and *triangular co-norms* (Hájek, 1998), respectively. The combination functions of some well-known fuzzy logics are shown in Table 3.

More formally, a *fuzzy (propositional) interpretation I* maps each elementary vague proposition *p* into the set of truth values [0,1], and is then extended inductively to all (complex) vague propositions (which are constructed from the elementary vague propositions by using the binary and unary logical operators $\wedge$, $\vee$, $\rightarrow$, and $\neg$) as follows (where $\otimes$, $\oplus$, $\triangleright$, and $\ominus$ are conjunction, disjunction, implication, and negation functions, respectively, as described above):

A fuzzy (propositional) knowledge base consists of a finite set of *fuzzy formulas,* which have one of the forms $\varphi \geq 1$, $\varphi \leq 1$, $\varphi > l$, or $\varphi < l$, where φ is a vague proposition, and l is a truth value from [0,1]. Such statements express that φ has a degree of truth of at least, at most, greater than, and lower than l, respectively. For example, $tall\_John \geq 0.6$ says that *tall_John* has a degree of truth of at least 0.6. Any such fuzzy knowledge base represents a set of fuzzy interpretations, which can be used to define the notions of *satisfiability, logical consequence,* and *tight logical consequence,* as usual. Here, it is important to point out the difference from Bayesian networks: rather than encoding one single probability distribution (over a set of binary interpretations), fuzzy knowledge bases encode a set of fuzzy interpretations.

Fuzzy Description Logics and Ontology Languages. In fuzzy description logics and ontology

Figure 6. Axioms for conjunction and disjunction functions

Axiom Name	Conjunction Function	Disjunction Function
Tautology / Contradiction	$a \otimes 0 = 0$	$a \oplus 1 = 1$
Identity	$a \otimes 1 = a$	$a \oplus 0 = a$
Commutativity	$a \otimes b = b \otimes a$	$a \oplus b = b \oplus a$
Associativity	$(a \otimes b) \otimes c = a \otimes (b \otimes c)$	$(a \oplus b) \oplus c = a \oplus (b \oplus c)$
Monotonicity	if $b \leq c$, then $a \otimes b \leq a \otimes c$	if $b \leq c$, then $a \oplus b \leq a \oplus c$

Figure 7. Axioms for implication and negation functions

Axiom Name	Implication Function	Negation Function
Tautology / Contradiction	$0 \rhd b = 1,\ a \rhd 1 = 1,\ 1 \rhd 0 = 0$	$\ominus 0 = 1,\ \ominus 1 = 0$
Antitonicity	if $a \leq b$, then $a \rhd c \geq b \rhd c$	if $a \leq b$, then $\ominus a \geq \ominus b$
Monotonicity	if $b \leq c$, then $a \rhd b \leq a \rhd c$	

languages, concept assertions, role assertions, concept inclusions, and role inclusions have a degree of truth rather than a binary truth value. Semantically, this extension is essentially obtained by (i) generalizing binary first-order interpretations to fuzzy first-order interpretations and (ii) interpreting all the logical operators by a corresponding combination function. Syntactically, as in the fuzzy propositional case, one then also allows for formulas that restrict the truth values of concept assertions, role assertions, concept inclusions, and role inclusions. Some important new ingredients of fuzzy description logics are often also fuzzy concrete domains, which include fuzzy predicates on concrete domains, and fuzzy modifiers (such as "very" or "slightly"), which are unary operators that change the membership functions of fuzzy concepts.

Figure 8. Combination functions of various fuzzy logics

	Łukasiewicz Logic	Gödel Logic	Product Logic	Zadeh Logic
$a \otimes b$	$\max(a+b-1, 0)$	$\min(a, b)$	$a \cdot b$	$\min(a, b)$
$a \oplus b$	$\min(a+b, 1)$	$\max(a, b)$	$a + b - a \cdot b$	$\max(a, b)$
$a \rhd b$	$\min(1-a+b, 1)$	$\begin{cases} 1 & \text{if } a \leq b \\ b & \text{otherwise} \end{cases}$	$\min(1, b/a)$	$\max(1-a, b)$
$\ominus a$	$1-a$	$\begin{cases} 1 & \text{if } a = 0 \\ 0 & \text{otherwise} \end{cases}$	$\begin{cases} 1 & \text{if } a = 0 \\ 0 & \text{otherwise} \end{cases}$	$1-a$

$$
\begin{aligned}
\mathcal{I}(\phi \wedge \psi) &= \mathcal{I}(\phi) \otimes \mathcal{I}(\psi) \\
\mathcal{I}(\phi \vee \psi) &= \mathcal{I}(\phi) \oplus \mathcal{I}(\psi) \\
\mathcal{I}(\phi \rightarrow \psi) &= \mathcal{I}(\phi) \rhd \mathcal{I}(\psi) \\
\mathcal{I}(\neg \phi) &= \ominus \mathcal{I}(\phi)
\end{aligned}
$$

As a fictional example, an online shop may use a fuzzy description logic knowledge base to classify and characterize its products. For example, suppose (1) textbooks are books, (2) PCs and laptops are mutually exclusive electronic products, (3) books and electronic products are mutually exclusive products, (4) PCs have a price, a memory size, and a processor speed, (5) *pc1* is a PC with the price 1300€, the memory size 3 GB, and the processor speed 4 GHz, (6) *pc2* is a PC with the price 500€, the memory size 1 GB, and the processor speed 2 GHz, (7) *pc3* is a PC with the price 900€, the memory size 2 GB, and the processor speed 3 GHz, (8) *ibm*, *acer*, and *hp* are the producers of *pc1*, *pc2*, and *pc3*, respectively. These relationships are expressed by the following description logic knowledge base:

(1) $Textbook \sqsubseteq Book$;
(2) $PC \sqcup Laptop \sqsubseteq Electronics$; $PC \sqsubseteq \neg Laptop$;
(3) $Book \sqcup Electronics \sqsubseteq Product$; $Book \sqsubseteq \neg Electronics$;
(4) $PC \sqsubseteq \exists hasPrice.Integer \sqcap \exists hasMemorySize.Integer \sqcap \exists hasProcessorSpeed.Integer$;
(5) $(PC \sqcap \exists hasPrice.1300 \sqcap \exists hasMemorySize.3 \sqcap \exists hasProcessorSpeed.4)(pc1)$;
(6) $(PC \sqcap \exists hasPrice.500 \sqcap \exists hasMemorySize.1 \sqcap \exists hasProcessorSpeed.2)(pc2)$;
(7) $(PC \sqcap \exists hasPrice.900 \sqcap \exists hasMemorySize.2 \sqcap \exists hasProcessorSpeed.3)(pc3)$;
(8) $produces(ibm, pc1)$; $produces(acer, pc2)$; $produces(hp, pc3)$.

The notions "expensive PCs", "PCs having a large memory", and "PCs having a fast processor" can then be defined as fuzzy concepts by adding the following three fuzzy concept definitions:

$ExpensivePC \equiv PC \sqcap \exists hasPrice.PCExpensive$,

$LargeMemoryPC \equiv PC \sqcap \exists hasMemorySize.MemoryLarge$,

$FastProcessorPC \equiv PC \sqcap \exists hasProcessorSpeed.ProcessorFast$.

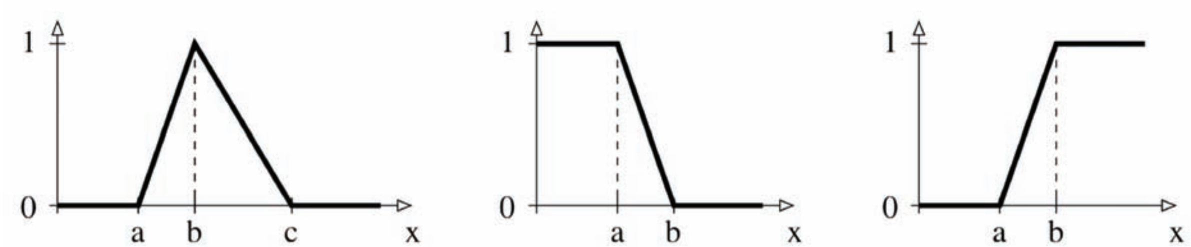
Here, *PCExpensive*, *MemoryLarge*, and *ProcessorFast* are fuzzy unary datatype predicates, which are defined by $PCExpensive(x) = rs(x; 600, 1200)$, $MemoryLarge(x) = rs(x; 1, 3)$, and $ProcessorFast(x) = rs(x; 2, 4)$, respectively, where $rs(x; a, b)$ is the so-called right-shoulder function (see Figure 9). Informally, as for the fuzzy concept "expensive PCs", every PC costing at least 1200€ (resp., at most 600€) is definitely expensive (resp., not expensive), while every PC costing between 600€ and 1200€ is expensive to some degree between 0 and 1.

Similarly, the notions "costs at most about 1000€" and "has a memory size of around 2 GB" in a buyer's request can be expressed through the following fuzzy concepts *C* and *D*, respectively:

$C \equiv \exists hasPrice.LeqAbout1000$ and $D \equiv \exists hasMemorySize.Around2$,

where $LeqAbout1000 = ls(500, 1500)$ and $Around2 = tri(1.5, 2, 2.5)$ (see Figure 9).

Figure 9. (a) triangular function tri(x; a, b, c), (b) left-shoulder function ls(x; a, b), and (c) right-shoulder function rs(x; a, b)



The literature contains many different approaches to fuzzy extensions of description logics and ontology languages. They can be roughly classified according to (a) the description logics or the ontology languages that they generalize, (b) the fuzzy constructs that they allow, (c) the fuzzy logics that they are based on, and (d) their reasoning algorithms.

One of the earliest works is due to Yen (1991), who proposes a fuzzy extension of a quite restricted sublanguage of *ALC*. Yen considers fuzzy terminological knowledge, along with fuzzy modifiers, but no fuzzy assertional knowledge, and he uses Zadeh Logic as underlying fuzzy logic. Yen's work also includes a reasoning algorithm, which allows for testing crisp subsumptions. Tresp and Molitor's work (1998) presents a more general fuzzy extension of *ALC*. Like Yen's work, it also includes fuzzy terminological knowledge, along with a special form of fuzzy modifiers, but no fuzzy assertional knowledge, and it is based on Zadeh Logic. The reasoning algorithm of Tresp and Molitor's work is a tableaux calculus for computing subsumption degrees.

Another important fuzzy extension of *ALC* is due to Straccia (1998, 2001), who allows for both fuzzy terminological and fuzzy assertional knowledge, but not for fuzzy modifiers, and again assumes Zadeh Logic as underlying fuzzy logic. Straccia's work also includes a tableaux calculus for deciding logical consequences and computing tight logical consequences. Hölldobler *et al.* (2002, 2005) extend Straccia's fuzzy *ALC* with fuzzy modifiers of the form $f_m(x) = x^\beta$, where $\beta > 0$, and present a sound and complete reasoning algorithm for the graded subsumption problem.

Straccia (2004) shows how reasoning in fuzzy *ALC* under Zadeh Logic can be reduced to reasoning in classical *ALC*. This idea has also been explored by Li *et al.* (2005a, 2005b).

Approaches towards more expressive fuzzy description logics include the works by Sanchez and Tettamanzi (2004, 2006), who consider the description logic *ALCQ*. They introduce the new notion of *fuzzy quantifiers*. As underlying fuzzy logic, they also assume Zadeh Logic. Their reasoning algorithm calculates the satisfiability interval for a fuzzy concept. Straccia (2005c) defines the semantics of a fuzzy extension of *SHOIN(**D**)*, which is the description logic that stands behind OWL DL. Stoilos *et al.* (2005a) use this semantics to define a fuzzy extension of the OWL language, and also propose a translation of fuzzy OWL to fuzzy *SHOIN*.

Other works include the one by Hájek (2005, 2006), who considers *ALC* under arbitrary t-norms and proposes especially a reasoning algorithm for testing crisp subsumptions. Bonatti and Tettamanzi (2006) provide some complexity results for reasoning in fuzzy description logics.

Recent works by Straccia (2005b, 2005a) present a calculus for *ALC(**D**)*, which works whenever the connectives, the fuzzy modifiers, and the concrete fuzzy predicates are representable as bounded mixed integer linear programs. For example, Łukasiewicz logic satisfies these conditions. The method has been extended to fuzzy *SHIF(**D**)*, which is the description logic standing behind OWL Lite, and a reasoner (called *fuzzyDL)* supporting Zadeh, Łukasiewicz, and classical semantics has been implemented and is available from Straccia's web page.

Towards reasoning in fuzzy *SHOIN(**D**)*,Stoilos *et al.* (2005, 2005b) show results providing a tableaux calculus for fuzzy *SHIN* without fuzzy general concept inclusions and under the Zadeh semantics. Stoilos et al. (2006) provide a generalization thereof that additionally allows for fuzzy general concept inclusions. In closely related work, Li *et al.* (2006) provide a tableaux calculus for fuzzy *SHI* with fuzzy general concept inclusions.

FUTURE RESEARCH DIRECTIONS

As the Semantic Web makes its transition from a vision to implementation, many of its stakeholders begin to feel the need to represent and reason under uncertainty. SW applications being developed for domains of knowledge in which uncertainty plays a significant role must include a means to store and retrieve incomplete knowledge. To cite just a few examples from the medical domain[f], statistical regularities linking a given protein to (say) Alzheimer's disease, the predisposition of patients with gene X towards developing cancer Y, or gene ontology evidence codes in support of a particular GO annotation of a gene can be all considered specific instances of more general cases in which a principled means for representing incomplete knowledge is needed. Similar situations can be observed in other domains of knowledge currently being studied in the context of the Semantic Web, which makes uncertainty representation and reasoning a rapidly growing field of SW research.

In early 2007, the W3C approved an incubator group to focus on uncertain knowledge. The URW3-XG[g] has the overall mission of better defining the challenge of reasoning with and representing uncertain information available through the WWW and related technologies. Accomplishing this mission involves identifying problems for which uncertainty is an essential aspect, to produce use cases, and to identify requirements for knowledge representation and reasoning when crisp truth-values are unknown or inappropriate. It is important to emphasize the fact that the group's scope does not include recommending a single methodology, but to investigate whether standard representations of uncertainty can be identified that will support requirements across a wide spectrum of reasoning approaches.

This stance is compatible with what we see as the future in this area. For most domains of knowledge, the task of representing the various distinct forms of uncertainty that might have a strong influence in the way knowledge is represented and applied is complex enough that the search for a "silver bullet" is inadvisable. That is, selecting a specific approach to be the definitive one for representing uncertainty would be a recipe for failure. In fact, a combination of approaches might be the best way to address the SW use cases involving uncertainty. For now, research on uncertain knowledge applied to the Semantic Web is gaining momentum but still lacks clear definitions, use cases, and applications. This state of affairs makes it difficult for developers to create useful solutions to most problems drawn from uncertainty-plagued domains, but the current rate of progress makes it clear to us that major change is near at hand.

APPENDIX: QUESTIONS FOR DISCUSSION

1. Cite a typical problem needing uncertainty representation and reasoning within the context of the Semantic Web.
2. Figure 2 displays the Bayesian Network from Figure 1 after evidence on pizza topping and base was included. Based on the results, which wine should a waiter suggest to the customer? Why?
3. What is "under the hood" of that reasoning process? How did the BN arrive at its conclusion?
4. What is the major limitation of BNs when applied to the SW?
5. What is the major advantage of using probabilistic extensions to DLs?
6. If Probabilistic FOL approaches cannot guarantee decidability in many cases, why should anyone care about using them?
7. What is the difference between uncertainty and vagueness?
8. Which are typical application areas for fuzzy formalisms?
9. What is the difference between probabilistic and fuzzy propositional interpretations? What is the difference between the semantics of Bayesian Networks and fuzzy propositional knowledge bases?

Answers:

1. See Introduction of this chapter.
2. According to the knowledge stored in that BN and the evidence entered, the waiter should suggest a red wine with medium to light body, delicate flavor. His first choice should be Beaujolais. Expert information from sommeliers and statistical regularities on previous orders were used to build this model, which allows it to make the best choice possible with the available information. For purposes of this example, "best" means the most likely wine a customer would order given the evidence.
3. The BN model uses Bayes rule to update the beliefs displayed in each of its nodes. After evidence was entered, an algorithm performed the belief updating in real time. See Charniak (1991) for a good introduction on BNs.
4. Apart from their flexibility and inferential power, BNs have only assertional expressivity and cannot represent situations where each problem instance involves reasoning about the same fixed number of attributes, with only the evidence values changing from problem instance to problem instance. This is insufficient for most SW problems. However, BNs can be applied in very specific cases, for which the representational power of BNs is sufficient.
5. Description logics are highly effective and efficient for the classification and subsumption problems they were designed to address. They provide decidability and their probabilistic extensions allow for representation of both numerical and structural aspects of a probabilistic model.
6. First Order Probabilistic Approaches have sufficient representational power for most real world problems. Additionally, they can provide ontology designers with a range of options to balance tractability against expressiveness.
7. Uncertainty expresses the lack of knowledge about binary statements, while vague-ness expresses the inherent imprecision of many-valued statements.

8. Some typical application areas for fuzzy formalisms are multimedia information processing and retrieval, natural language interfaces to the Web, ontology mapping, information retrieval, and e-commerce negotiation tasks.
9. A probabilistic propositional interpretation maps binary interpretations to a degree of likelihood in [0, 1], while a fuzzy propositional interpretation maps elementary vague propositions to a degree of truth in [0, 1]. A Bayesian Network encodes a probability distribution over a set of binary interpretations, while a fuzzy propositional knowledge bases encodes a set of fuzzy propositional interpretations.

Chapter 7.4
Semantic Web-Enabled Protocol Mediation for the Logistics Domain

Oscar Corcho
Universidad Politécnica de Madrid, Spain

Silvestre Losada
Intelligent Software Components, S.A., Spain

Richard Benjamins
Intelligent Software Components, S.A., Spain

ABSTRACT

Among the problems that arise when trying to make different applications interoperate with each other, protocol mediation is one of the most difficult ones and for which less relevant literature can be found. Protocol mediation is concerned with non-matching message interaction patterns in application interaction. In this chapter we describe the design and implementation of a protocol mediation component that has been applied in the interoperation between two heterogeneous logistic provider systems (using two different standards: RosettaNet and EDIFACT), for a specific freight forwarding task.

DOI: 10.4018/978-1-60566-066-0.ch004

CURRENT SITUATION

Logistics is defined as the art and science of managing and controlling the flow of goods, energy, information and other resources like products, services and people from the source of production to the marketplace. As pointed out by Evans-Greenwood and Stason (2006) the current trend in logistics is to divide support between planning applications, which compute production plans overnight, and execution applications, which manage the flow of events in an operational environment. This disconnection forces users to deal with business exceptions (lost shipments, for example), manually resolving the problems by directly updating the execution and planning applications. However, this human-dependency problem can be ameliorated by using Web technology to create a heterogeneous composite application involving all participants in the process, providing a complete Third-Party Logistics solution, and giving users a single unified view into the logistics pipeline. This consolidated logistics solution greatly simplifies the task of identifying and correcting business exceptions (e.g., missing shipments or stock shortages) as they occur. Therefore, logistics management is a typical business problem where the use of a service oriented architecture is clearly suited.

Furthermore, Evans-Greenwood and Stason (2006) also talk about the possibility of combining multiple Third-Party Logistics solutions into a single heterogeneous virtual logistics network. With such a virtual network, each shipment is assigned a route dynamically assembled from one or more individual logistics providers, using dynamically created virtual supply chains. Most of these business functions are still manual and offline, but most of them can be automated with the use of service oriented architectures, as will be presented in this chapter. Obviously, the main advantages of using such solutions are the decreases in cost and speed in transactions, which influence in a better quality of the service provided to customers.

The main barrier to set up a business relationship with a company in the logistics domain is that it usually requires an initial large investment of time and money. This is ameliorated by the emergence of some industry standards like EDIFACT (EDIFACT), AnsiX12 (AnsiX12) or RosettaNet (RosettaNet), which ease the integration tasks between information systems that comply with them. However, given that these standards have some flexibility in what respects the content and sequencing of the messages that can be exchanged, the integration of systems is still time and effort consuming. Besides, there is sometimes a need to integrate systems that use different standards, what makes the integration task even more time and effort consuming.

This is the focus of one of the four case studies developed in the context of the EU project SWWS[1] (Semantic-Web enabled Web Services), a demonstrator of business-to-business integration in the logistics domain using Semantic Web Service technology. All the features of this demonstrator are described in detail by Preist and colleagues (2005), including aspects related to the discovery and selection of relevant services, their execution and the mediation between services following different protocols.

In this chapter we will focus on the last aspect (mediation) and more specifically on protocol mediation, which is concerned with the problem of non-matching message interaction patterns. We will describe the design and implementation of the protocol mediation component applied in this case study to show how to make logistic provider systems using two different standards (RosettaNet and EDIFACT) interoperate for a specific freight forwarding task.

The chapter is structured as follows. The rest of this section introduces a motivating example, focusing on the needs for protocol mediation, and gives some background on how the problem of mediation can be characterised in general and on the approaches for mediation proposed in the context of Semantic Web Service research. Section 2 summarises the protocol mediation approach followed for this case study and the main elements to be considered inside the approach. It also describes the ontology used for the description of the abstract and concrete protocols used by the entities involved in the message exchange. Section 3 provides an overview of the API of the protocol mediation component and gives details about how to configure it for deployment. Finally, section 4 gives some conclusions.

An Example in the Logistics Domain

Let us imagine that we have a manufacturing company in Bristol, UK, which needs to distribute goods internationally. The company outsources transportation into other companies, which offer *Freight Forwarding Services*. These companies may be providing the transportation service by themselves or just act as intermediaries, but this is not important for the manufacturing company. However, the manufacturing company still needs to manage relationships with these service providers, as a *Logistics Coordinator*, being responsible for selecting the service providers, reaching agreements with them with respect to the nature of the service that they will provide, coordinating the activity of different service providers so as to ensure that they link seamlessly to provide an end-to-end service (e.g., if a ship company transports a goods to a port, then the ground transportation company should be waiting for those goods with a truck to transport them to an inland city), etc.

The manufacturing company uses EDIFACT for its exchange of messages with the service providers. However, not all of them use this standard, but in some cases RosettaNet. So the situation can be that two different companies that can offer the same service (e.g., road transportation inside Germany) are using two different standards and the logistics coordinator should be able to use any of them, independently of the protocol that they use in their information systems, taking only into account the business requirements that the parcel delivery may have (quality of service, speed, price, insurance, etc.). In this situation there is a need for a seamless integration of a mediation component that is able to capture the EDIFACT messages sent by the Logistics Coordinator into RosettaNet ones that are sent to the corresponding Freight Forwarding Service, and vice versa, without any change to the information systems of any of the parties involved.

Mediation in Service Oriented Architectures and in Semantic Web Services

In **service oriented architectures**, mediation services are middleware services that are in charge of resolving inconsistencies between the parties involved in a sequence of message exchanges. Mediation can be considered at different levels:

- **Data mediation:** Transformation of the syntactic format of the messages.
- **Ontology mediation:** Transformation of the terminology used inside the messages.
- **Protocol or choreography mediation:** Transformation of sequences of messages, to solve the problem of non-matching message interaction patterns.

All types of mediation are important to achieve a successful communication between the services involved in an application, and each of them poses different challenges. In this chapter we will focus on aspects related to the last type of mediation, which is the one aimed at ensuring that, from a high-level point of view, the services involved in a message exchange achieve their overall goals. In other words, it aims at mapping the patterns of conceptually similar, but mechanically different interaction protocols sharing a similar conceptual model of a given domain.

The atomic types of mismatches that can be found between a set of interaction patterns are (Cimpian and Mocan, 2005):

- **Unexpected messages:** One of the parties does not expect to receive a message issued by another. For instance, in a request for the delivery of a parcel the logistics provider sends the parcel weight and size, the departure place and the arrival place, while the freight forwarding service does not expect the parcel weight and size, since it will not use this information.
- **Messages in Different Order:** The parties involved in a communication send and receive messages in different orders. In the previous case the sender may send the messages in the order specified above while the receiver expects first the arrival

place and then the departure place.

- **Messages that Need to be Split:** One of the parties sends a message with multiple informations inside it, which needs to be received separately by the other party. In the previous example, the sender sends the arrival and departure places in one message, while the receiver expects it as two messages.
- **Messages that Need to be Combined:** One of the parties sends a set of messages that the receiver expects as a single message with the multiple information. We can think of the inverse situation to the one aforementioned.
- **Dummy Acknowledgements or Virtual Messages that Have to be Sent:** One of the parties expects an acknowledgement for a certain message, but the receiver does not issue such acknowledgement; or the receiver expects a message that the sender is not prepared to send.

One of the purposes of the work on **Semantic Web Services** is the automation of some of the tasks involved in the development of applications that follow a service oriented architecture. As a result, some work on mediation has been done in the area. If we focus on protocol mediation, we can find the following two approaches:

Priest and colleagues (2005) and Williams and colleagues (2006) describe the approach followed in the context of SWWS, and which will be described in more detail in the next section. This approach is based on the use of a general abstract state machine that represents the overall state of the communication between parties, and a set of abstract machines for each of the parties in the conversation, which specify their state and the sets of actions to be performed when they receive a set of messages or when they have to send a set of messages.

In the context of the WSMO initiative, Cimpian and Mocan (2005) describe the approach taken for the design and implementation of the process mediator for the Semantic Web Service execution engine WSMX. This approach is similar to the previous one, since it is also based on the use of an abstract machine with guarded transitions that are fired by the exchange of messages and the definition of choreographies for each of the parties involved in the communication.

PROPOSED SOLUTION: THE SWWS APPROACH FOR PROTOCOL MEDIATION

This section describes briefly the main components involved in our protocol mediation approach. A more detailed explanation is provided in (Williams et al., 2006), and Figure 2 shows an example of the use of all these components in the logistics domain described in the introduction.

Communicative Acts

Communicative acts are the basic components of the communication. They are modelled as sequences of four events that are exchanged between systems and the underlying communication infrastructure when sending a message (see Figure 1), as follows:

- `.request.` The initiator sends a message to the communication infrastructure.
- `.indication.` The responder receives the message from the communication infrastructure.
- `.response.` The responder acknowledges the receipt of the message.
- `.confirm.` The initiator receives the acknowledge receipt.

Both the .response and .confirm primitives model an acknowledgement that the communication has reached its intended recipient. Any substantive response motivated by the communicative act itself is modelled as a subsequent communicative act in the opposite direction.

At the initiator, the outcome of a communicative act may be a success (the initiator knows that the communication has reached the intended recipient), an exception or failure (the initiator knows that the communication has failed to reach the intended recipient), or indeterminate (the initiator does not know the outcome of the communication).

Abstract Protocols and Roles

When we described protocol mediation, we commented that systems involved in a message exchange have conceptually similar interaction protocols. This high-level conceptual protocol is described by means of an abstract protocol.

The abstract protocol can be then defined as a multi-party choreography that describes the constraints that govern the sequencing of communicative acts between the systems engaged in an interaction. Each system takes on one or more roles (e.g., buyer, seller, logistics provider, freight forwarder, etc.) with respect to a choreography. The choreography then describes each of these roles in terms of the sequencing constraints on the exchange of primitives between the communication infrastructure and the system adopting the role.

Concrete Protocols

Each of the systems involved in a message exchange may have different mechanics by which communicative acts are managed. For each communicative act event in each system we will have then a concrete protocol that describes this behaviour.

Hence concrete protocols describe what happens at an initiating system in response to an admissible .request primitive and prior to (and after) the corresponding .confirm primitive. Likewise, at a responding system in response to the stimuli that give rise to an .indication primitive, the behaviours that occur between that and the corresponding .response and the behaviours that occur after that.

Processes as Abstract State Machines

The abstract and concrete protocols are described by means of processes, which in our approach are implemented by concurrent finite state machines.

Figure 1. A communicative act and its four events (Williams et al., 2006)

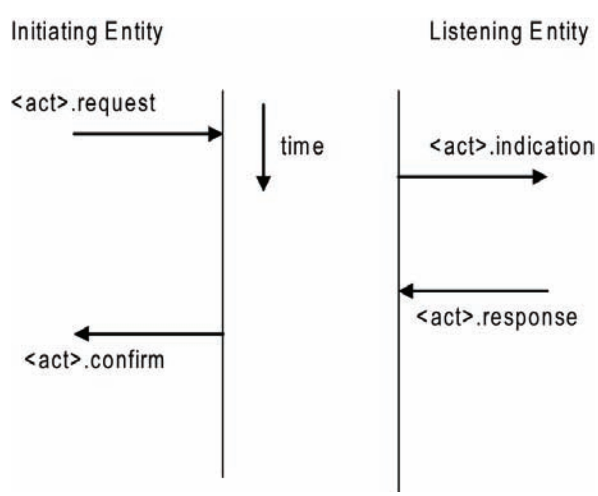

Figure 2. Abstract and some concrete protocols in the logistics domain (adapted from Williams et al., 2006)

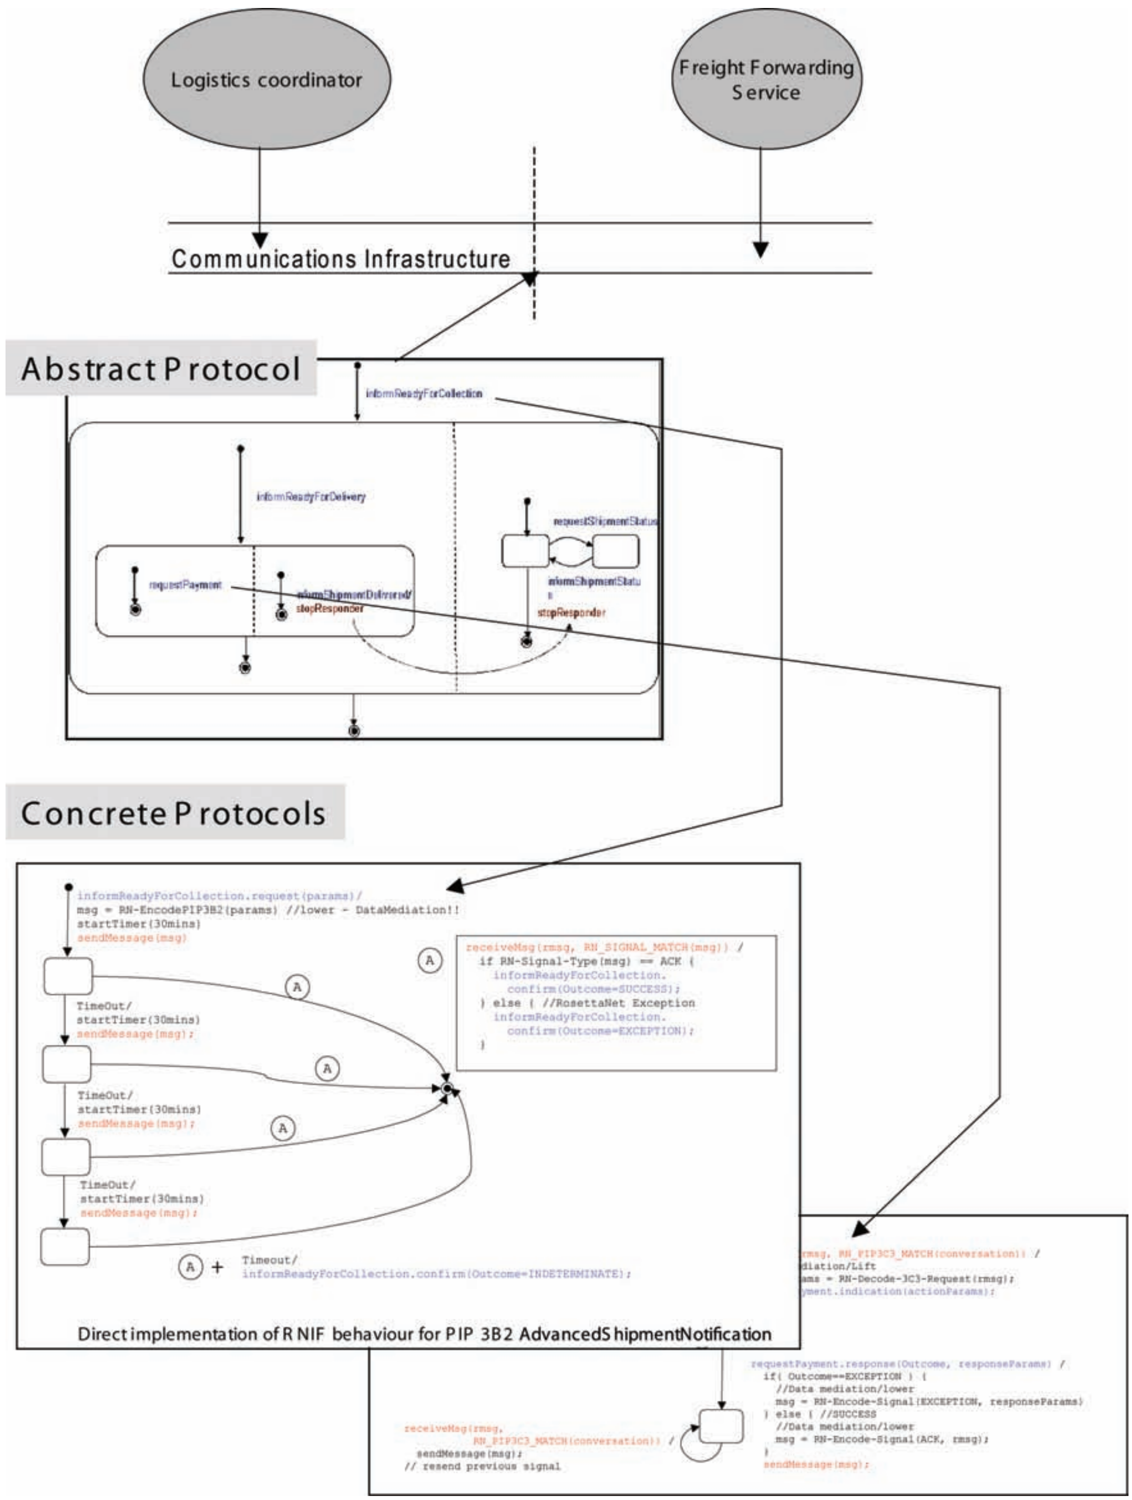


For abstract protocols a state represents the state of the high-level conversation in the context of the common multi-party choreography (e.g., a request for payment has been issued by the freight forwarding service and received by the logistics coordinator). For concrete protocols a state represents some intermediate state in the behaviours associated with the issuing of .request and .confirm primitives or issuing .indication and .response primitives.Transitions between states may be driven by different internal and external actions, as follows:

1. *PrimitiveDriven transitions*. In abstract protocols they can be any of the primitives of a communicative act. In concrete protocols, they can be only <act>.request or <act>.response primitives, since these primitives can initiate the state machines associated to a concrete protocol.
2. *EventDriven transitions*. They are used to communicate between concurrent processes (a process may raise an event that is being waited for by another process). They are normally used in communication exchanges between more than 2 parties and in concrete protocols (e.g., two processes are waiting for the same payment under different payment procedures, credit card or cheque, and one of them is satisfied).
3. *TimeDriven transitions*. They occur on the expiry of a time interval following the entry to the state that has the time driven transition associated. They can be used in any type of protocol (e.g., in an abstract protocol, the system will have a timeout feature to send another communicative act if a response has not been received in a given time).
4. *MessageDriven transitions*. They occur only in concrete protocols, when a message is received from the communication infrastructure and filtered according to a template, so that the relevant information is extracted (e.g., for a freight forwarding service, if a request for a shipment service is broadcasted through the communication infrastructure, this could activate it so that it provides its service to the logistics provider).

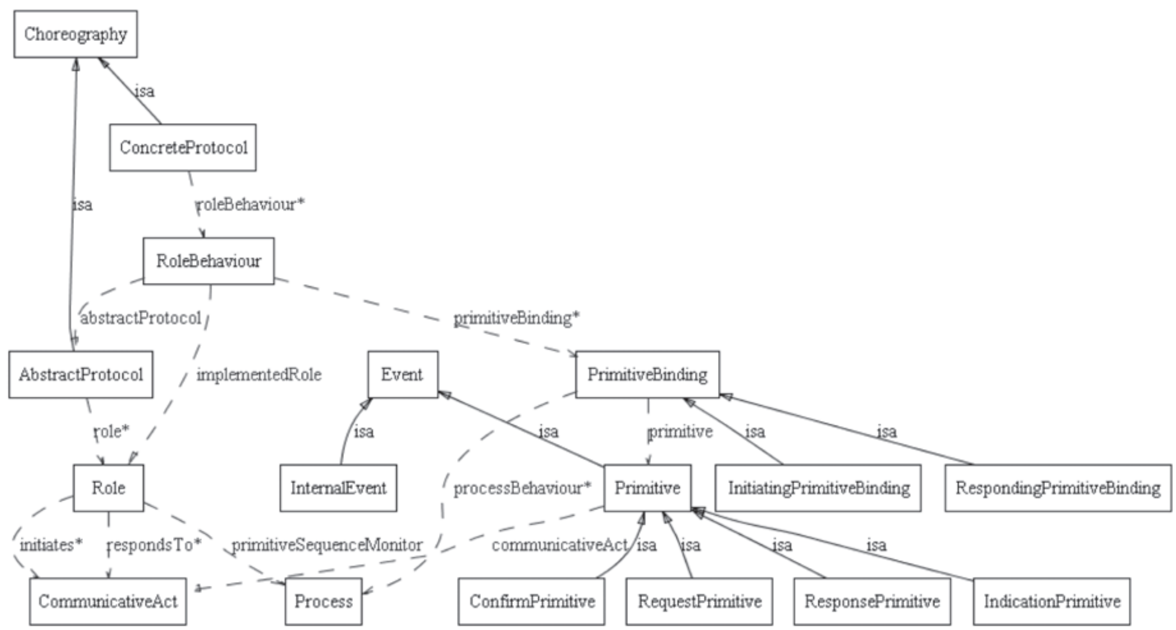
All the transitions have associated a transition condition guard (a Boolean expression that determines whether the transition can be actually performed given the state where the state machine is and the external and internal conditions) and a transition behaviour. Transition behaviours model the actual transition logic to be done besides moving from one state to another. They include (both for abstract and concrete protocols): raising .indication or .confirm primitives, raising events to concurrent processes, and instantiate concurrent processes. For concrete protocols they may also include: perform transformations on received message structures, generate message structures for transmission, and extract, maintain and manipulate information taken from message fields.

AN ONTOLOGY FOR DESCRIBING ABSTRACT AND CONCRETE PROTOCOLS

Figure 3 and Figure 4 show different parts of the very simple choreography language (VSCL) ontology, which is available at http://swws.semanticweb.org/. This ontology can be used to describe the abstract and concrete protocols presented in the previous section, together with all their components, and is used to configure the protocol mediation component described in the next section.

As shown in Figure 3, choreographies are divided into abstract and concrete protocols. An abstract protocol specifies a set of roles that identify the role that a system is playing in an exchange of messages (logistics coordinator, freight forwarding service, etc.). Each role contains a set of communicative acts that are considered in the shared abstract protocol and that allow defining the

Figure 3. Ontology excerpt related to abstract and concrete protocols and communicative acts



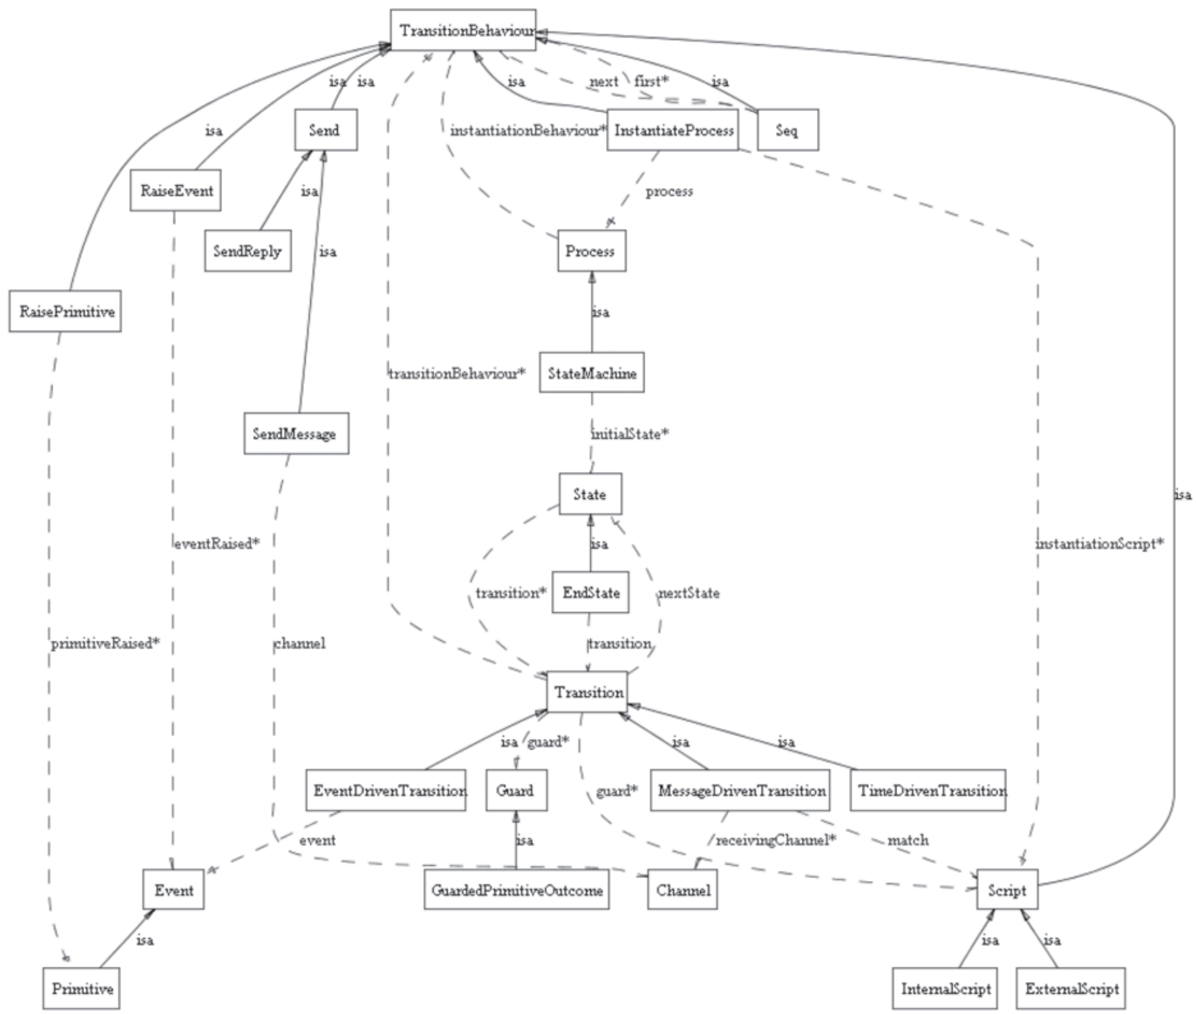
shared conceptual model of the message exchange patterns to be followed by all the systems participating in a conversation. For each of these roles in each abstract protocol and with each specific implementation of any of the systems involved there is one role behaviour, that implements a set of concrete protocols that correspond to the behaviour that the actual system for the different communicative acts that are defined for it.

The admissible sequences of communicative acts are specified in what we call a process, whose common implementation will be a state machine, as we will see in the next figure. The primitives that are considered are those that were described when we discussed communicative acts: request, indication, confirm and response.

Finally, each concrete protocol contains one or more instances of RoleBehaviour. Each instance of RoleBehaviour declare a role that may be adopted by a peer to interact with the service provider agent via its interface. Each RoleBehaviour and carries a PrimitiveBinding for each RequestPrimitive and IndicationPrimitive associated with the role. This divides PrimitiveBinding into two subclasses, InitiatingPrimitiveBinding for binding instances of RequestPrimitive and ListeningPrimitiveBinding for bindings associated with instances of IndicationPrimitive. Each instance of PrimitiveBinding associates an instance of Process with the corresponding primitive. The Process(es) associated with an InitiatingPrimitiveBinding are instantiated when an admissible invocation of the corresponding RequestPrimitive occurs. The Process(es) associated with a ListeningPrimitiveBinding are instantiated either when the corresponding conversation is instantiated or as the conversation progresses and the IndicationPrimitive associated with the binding becomes admissible.

Figure 4 illustrates the classes used to represent state machines in VSCL. A state machine is a type of process that is composed of a set of states (some of which can be end states). Each state can have a set of associated transitions, which specify the next state, a set of guards and a set of transition behaviours. Transitions can be of different types, as described in the previous section (event driven, time

Figure 4. Ontology excerpt related to the state machine descriptions



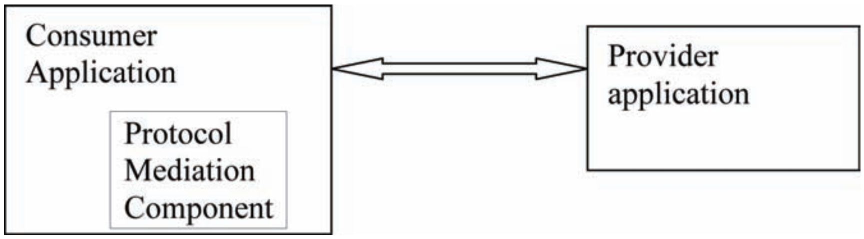
driven, or message driven). The primitive driven transitions were already specified in Figure 3 as initiating and responding primitive bindings, since they are responsible for starting a state machine.

Transitions behaviours are of different types, as pointed out in the previous section. From them, the most relevant is the script, which can be provided by a reference to a URL (external) or as part of the instance values (internal). We will analyse them in more detail later, when we discuss the component API.

In our logistics application we have a state machine for each of the protocols aforementioned. In summary, in our logistics application we have the following instances of this ontology (available at http://swws.semanticweb.org/):

- One abstract protocol with two roles defined for it: FreightForwardingServiceConsumer and FreightForwardingServiceProvider.
- 14 processes (state machines) for concrete protocols.
- Six communicative acts: InformReady-ForCollection, RequestShipmentStatus, InformShipmentStatus, InformReady-ToDeliver, InformShipmentDelivered, and

Figure 5. Location for the deployment of the protocol mediation component



RequestPayment, with their corresponding primitives (four for each of them).

- 10 event driven transitions with 20 scripts for their transition behaviours.

SOLUTION DETAILS: THE SWWS PROTOCOL MEDIATION COMPONENT

Here we provide a general description of the protocol mediation component architecture and of important implementation details, including a broad description of the component API, so that it can be used in other similar applications with protocol mediation needs.

Though the usual deployment of a protocol mediation component would be as part of the communication infrastructure between services in a service-oriented application, in our case this component has been deployed as shown in Figure 5: A consumer application incorporates the protocol mediation component inside its environment in order to control the exchange of messages with the provider application. In our logistics application, the selection of one system or another as consumer or provider is arbitrary. Our decision has been to use the logistics coordinator as a consumer and the freight forwarding service as a provider.The protocol mediation component has 5 essential subcomponents, which are described in detail in the next sections:

- **Local agent** (package com.isoco.swws.conversation.local_agent). It is the subcomponent directly used by the final user. Basically, the component allows creating conversations, initiating them in an active or a passive mode and later, by means of the ConversationManager, explicitly invoking the different CommunicativeActs and tracing the interactions with the remote conversation partner.
- **Protocol** (package com.isoco.swws.conversation.abstractprotocol). It is the internal representation of the protocols (either abstract or concrete) that rule the conversation. This is based on the ontology described in the previous section.
- **ChoreographyHandler** (package com.isoco.swws.conversation.mediation.vscl). It is the bridge between the application and the external choreography that is included in the VSCL ontology.
- **Message transfer plugin** (package com.isoco.swws.conversation.plugins). Internally, a specific communication protocol (HTTP, SMTP, etc.) is used for the communication between the consumer and the provider. This plugin serves as an interface for the protocol. This implementation of the component includes an HTTP plugin, but other plugins could be easily created and deployed.
- **Rhino facilites** (package com.isoco.swws.conversation.environment). They are used to execute the Javascript scripts included

in the choreography. The mechanism used in the component is Rhino (Mozilla) and there is an abstraction layer to ease its use and to adapt it to the application needs.

Local Agent

The local agent groups the collection of classes that the Consumer needs to create and control a conversation. A conversation is initiated with the creation of a *ConversationManager*, which receives the following parameters in its constructor:

- A set of roles (the systems involved in a conversation). The InterfaceRole contains the *remoteInterface*, the URL that holds the address of the conversation's partner, and the *localRole*, the URL of the role adopted by the local agent with respect to the choreography and this conversation.
- The URL where to find the choreography (that is, the place where the VSCL ontology instances are stored).
- An indication handler, which is used in the case that an external system has to contact this system or send it and event. Normally this handler is used when the system receives a message from the provider that causes a <CommunicativeAct>.indication. This is the way that the protocol mediation component has to inform an application that an indication has arrived. It is also responsibility of the IndicationHandler to respond to the indication of the CommunicativeAct. Responding to the .indication means to model the .response. The user must calculate the outcome and the results of that CommunicativeAct.

The implementation of the IndicationHandler is robust enough to deal with situations where it could be blocked or fail, where the response will be launched again.

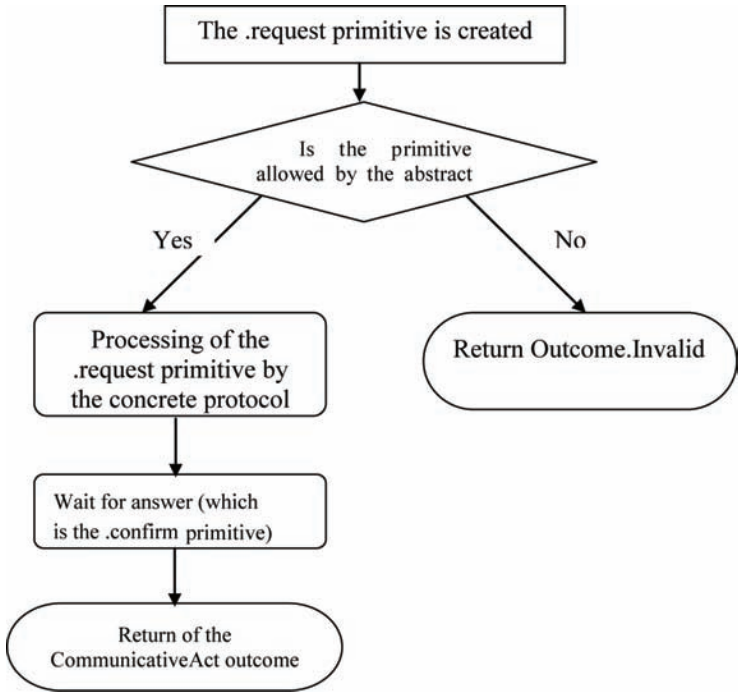
A conversation consists in the coordinated exchange of communicativeActs. The local agent can send CommunicativeActs either in a **synchronous** or an **asynchronous** way. In the synchronous exchange the communicative act is sent and the system waits for the confirmation of the remote partner. In the asynchronous exchange the communicative act is launched and the control is returned back to the application. When the confirmation from the user is received, the *confirm* method of the ConfirmHandler interface that has been specified as a parameter is invoked.

The creation of a new ConversationManager implies the following tasks: initializing the abstract and concrete protocols and initializing of the ChoreographyHandler for the successive uses of the choreography. A conversation that has been created can be initiated in two modes: **active** and **passive**:

- In the active mode, the Consumer can invoke the *synchSay* and the *asynchSay* methods (for synchronous and asynchronous exchanges of messages) to start the exchange of CommunicativeAct with the remote partner.
- In a passive mode, the *listen* method must be invoked to initiate a conversation in a passive mode. This action prevents the use of the *synchSay* and the *asynchSay* methods and the conversation waits for an indication from the remote partner. It should be noted that once the *listen* method is invoked, the conversation will only be activated by a remote message from the partner. There is no explicit method to transfer the conversation to the active mode.

Figure 6 shows how this works in an active mode: the .request primitive is created for a CommunicativeAct. This primitive is sent to the abstract protocol to know if the CommunicativeAct can be initiated in the current context of the conversation.

Figure 6. Usual process followed for a communicative act being sent



- If it cannot be initiated, the execution is aborted and Outcome.INVALID is returned to the entity to inform that it is impossible to execute that action in the current situation.
- If it can be initiated, the primitive is sent to the concrete protocol in order to execute the set of scripts and other relevant actions associated to this primitive. It is important to emphasize that the primitive is sent, that is, there is no explicit communication from the abstract protocol to the concrete protocol. The idea is that the abstract protocol allows executing the primitive but it does not consume it. Afterwards, we wait to receive the .confirm primitive and the Outcome associated to the CommunicativeAct of the primitive is returned. The outcome can be: Outcome. SUCCESS, Outcome.EXCEPTION, or Outcome.INDETERMINATE.

When the entity is waiting for an indication, the process is different. When a message arrives, it is evaluated in the MessageDrivenTransitions of the active processes of the concrete protocol. If any of them matches, that transition is executed and it will be its responsibility, among other responsibilities, to launch an .indication primitive to the abstract protocol to check if in the context of this conversation that primitive is allowed. If the primitive is allowed, the entity will be informed about it by the indication method of the IndicationHandler.

Multiple Conversations

The exchange of messages between the consumer and the provider is executed in a multiple simultaneous conversations scenario. To know which conversation should process each message, the protocol mediation component associates a unique conversation id to each ConversationManager.

Whenever a conversation is initiated by a partner, a message is sent with a parameter that informs that it is a new conversation. A new conversation id is created for this conversation and the following messages of this conversation must include this id.

The ConversationDispatcher class is responsible for registering all the existing conversations. Basically there are two lists: a list of active conversations and a list of potential conversations (those that are waiting to receive a message to start, by the invocation of the method *listen*). When a message to start a conversation arrives, all the conversations that are waiting are checked to inquire which one can process it. If a conversation can process it, that conversation is moved to the list of active conversations.

The ConversationDispatcher is also responsible for initializing all the available plugins once a conversation starts.

Protocols

Conversations are ruled by a choreography, which contains two types of protocols (abstract and concrete). Both protocols are specified by means of the ontology described in section 2.5. For each class in the ontology there is a Java class in this package, including the states and transitions.

Each ConversationManager has references to its own abstract and concrete protocols. When a conversation is created, the ConversationManager loads the initial processes with all their associated structure, using those Java classes (as explained in the following section). The list of processes and active states is updated as the transitions are executed.Transitions are modelled with the Transition Java class and its subclasses. The following methods are called for a transition:

- **Evaluate initTransition.** This function must be redefined by all the subclasses of Transition. It has two responsibilities: verify that the object that it receives is the instance that it knows how to process. For example, the EventDrivenTransition must guarantee that the object type is 'Event'. Not only must it guarantee that it has the correct type, but also that it is the instance that sets off the transition (for example, that it is the RequestShipmentStatus.request primitive). Its other responsibility is to initiate whatever is necessary to execute the transition. For example, to set some variable in the RhinoEnvironment or some other task.
- **Evaluate initGuard.** The transitions can have an associated guard that must be satisfied to continue with the transition. In general, it is a method that does not have to be redefined by the subclasses.
- **Execute doBehaviours.** As a consequence to the execution of the transition, a set of TransitionBehaviours must be executed. These behaviours represent what the transition does. This method should not be modified. As we will see, transition behaviours are specified in Javascript and executed by the RhinoEnvironment.
- **Execute advanceToNextState.** A change to the new state is performed in order to end the execution of a transition. This process entails several tasks such as the loading of all the structure of the new state from the choreography, the initialization of the associated TimeDrivenTransitions, etc.

Choreography Handler

It serves as a bridge between the application and the choreography. It is used to create instances of the classes included in the Protocols package from the choreography information available in a URL. As aforementioned, the whole choreography is not loaded completely from the start but incrementally according to the transitions done through the abstract and concrete protocols. Two significant methods from this class are:

- *createProcessByName*, which creates a state machine from the information available in its location (URL). It returns the state machine and all the structure associated to it (states, transitions, transition behaviours, scripts, etc.).
- *createStateByName*, which creates a state from its name (URI). It returns the state and all the structure associated to it (transitions, transition behaviours, scripts, etc.).

This component uses the KPOntology library[2] to navigate the RDF graph that models the choreography.

Message Transfer Plugin

This component deals with the specific communication protocol (HTTP, SMTP, etc.) used for the communication between consumers and providers. An HTTP plugin is included with the current implementation, and other plugins can be also created.

The HTTP plugin provided is made up of the HttpPlugin class and an auxiliary Web application that manages the queue of received messages, with two services:

- Receive a message. This service is used when a remote partner, e.g. the provider, must send a message to the consumer. The Web application receives the message and puts it in the queue of received messages.
- Recover the message. This service allows the HttpPlugin class to recover the messages received from the Web application.

The HttpPlugin class has two main objectives:

- Send messages to remote partners, using the sendMessage method. This method receives a remote address where to send the message, the conversation id, and the message.
- Transfer messages from the Web application to the component. The HTTP plugin has a thread that is constantly polling the Web application for the arrival of new messages.

The Web application always responds to the petition of messages by means of an XML that contains the following elements:

- **conversationId:** id of the conversation under way.
- **newConversation:** it indicates if it is a new conversation.
- **Message:** Depending on the types of message, it will have different types of structures. For instance, in the case of the RosettaNet messages, it will be divided into: “Preamble”, “DeliveryHeader”, “ServiceHeader” and “Content”.

It is the responsibility of the plugin to find the appropriate Conversation Manager from the conversation id, to build the internal structure of the protocol for the representation of the messages and to send the resulting message to the Conversation Manager for its processing.

Messages and Filters

All messages are vectors of XML structures, so that they can accommodate multi-part messages that are typical in B2B interactions. The underlying messaging system plugins are responsible for encoding/decoding between the internal XML structures (typically XML DOMs or more abstractly XML Infosets) and the packaged and encoded wire format - this includes XML validation of inbound messages against the relevant DTDs and/or XML schema. Directly or indirectly the concrete interface descriptions MUST provide message DTD/

Schema and lift/lower transformations.

In addition, received message structures also carry low-level connection and endpoint information. Typically this will not be used directly in processing the message, but is essential for the plugins to correctly formulate a response message - in particular if a response/reply needs to be returned on the same connection as a given received message.

Message are filtered and classified according to the various pieces of typing information that they carry: internet media type, XML DOCTYPE and XML root element type of the primary part of the message; and identification of the endpoint via which they were received. This associates a received message with a collection of processes which serve messages of a given kind. Concrete Role behaviour descriptions contain a static description of the message types they are able to receive.

Messages with the same conversation id are bound to a particular conversation and queued to be processed by the concrete role behaviours associated with that process - in particular messages are consumed by message driven transitions. When a message matches a message filter in the initial transition of a listening role behaviour, a factory behaviour is invoked which instantiates a new instance of a conversation (controller) and passes that new message to that controller - a new conversation id value becomes associated with the new conversation.

So coarse filtering is used to associate messages with a class of conversational role where they may either be queued at an existing conversation or used to instantiate a new conversation. Messages queued at a conversation are then visible to the processes that realise the concrete role behaviours for that conversation. As discussed earlier these may or may not be processed in strict arrival order.

Message Filtering

This component eases the use of Rhino, the Javascript interpreter used by the protocol mediation component to express message filters, transition pre-conditions and some (scripted) transition behaviours. Each process specified in the choreography has a Rhino Environment, and each environment will have a defined scope. This scope has a set of variables and functions defined in the scripts. In this way, the processes do not share the execution environment when they execute the scripts.

The abstraction layer of Rhino is achieved through the RhinoEnvironment class. The most distinguishable of its functions are:

- *execute*, which receives a script as a parameter and executes it.
- *match*, which receives a script that returns a Boolean value, executes it and returns that Boolean value.
- *setMessage*, which receives a variable name and its value, and is in charge of creating in the Javascript environment a variable with that value.
- *getMessage*, which returns the value of a variable name in the Javascript environment.

Deployment and Installation

The protocol mediation is a framework designed to be used by a client application. The typical scheme for its use would be:

- Initialize the ConversationDispatcher.
- Create a ConversationManager, specifying the choreography, the participating agents and the Indicationhandler. The implementation of the IndicationHandler must guarantee that all the possible .indication communicative acts that the remote partner can send are processed and for each one

of them, it must compute the Outcome and the adequate results.

- Initiate the exchange of CommunicativeActs with the remote partner.

Next, we show an example on how to use the component in Box 1. The objective of this example is to give a guidance on the use of the component. The typical use must be by means of an application that should keep the evolution of the conversation as well as the CommunicativeActs that have been sent and received by the remote partners.

The first thing to do is the initialization of the ConversationDispatcher. This initialization also includes the initialization of the plugins. In the previous example, the URL is the address of the local Web application that uses the HTTP-Plugin.

The second thing to do is the creation of the ConversationManager. In the previous example we talk to the partner that we can reach at "http://provider:8080/". In the conversation we adopt the role of the FreightForwardingServiceConsumer. The choreography is found in http://swws.semanticweb.org/logistics.owl. We also have the IndicationHandlerImpl which is an implementation of the IndicationHandler.

Afterwards, a CommunicativeAct is created (in this case: InformReadyForCollection) and we send it in a synchronous way.

To keep the example simple we do not send any parameter in the comunicativeAct, but it would be usual practice.

ALTERNATIVES, COST AND BENEFITS

The proposed solution to protocol mediation between heterogeneous applications can be applied not only to the logistics domain, which is the one that has been described in this chapter, but also to other similar domains where applications are already deployed and have to interoperate with each other in order to support a specific set of added-value functionalities.

While work on the area of data mediation in service exchanges is quite widespread and there are tools available in the mainstream market for solving these issues, most of the approaches for protocol mediation have been based on ad-hoc

Box 1. Partial OCML code defining location parameter instance and respective MSS member.

```
(def-instance brighton-location location
    ((has-instance-title "Brighton")
    (defined-by p2-location-brighton)))

String logisticsNamespace = "http://swws.semanticweb.org/logistics#"
ConversationDispatcher.init("http://consumer:8080/");
interfaceRole = new InterfaceRole(new URI("http://provider:8080/"),
    new URI(logisticsNamespace + "FreightForwardServiceConsumer"));
IndicationHandlerImpl indct = new IndicationHandlerImpl();
ConversationManager conversationManager = new ConversationManager(
    new InterfaceRole[]{interfaceRole},
      new URI("http://swws.semanticweb.org/logistics.owl"), indct);
CommunicativeAct communicativeAct = new CommunicativeAct(new URI(logisticsNamespace +
"InformReadyForCollection"));
conversationManager.synchSay(communicativeAct);
communicativeAct = new CommunicativeAct(new URI(logisticsNamespace + "RequestShipment-
Status"));
conversationManager.synchSay(communicativeAct);
```

solutions that are tightly related to the applications where they are being applied. No easy configurable toolkit exists yet for solving this problem, hence the main alternative for the work proposed here is to create an ad-hoc solution that solves the interaction problem between applications or services for a specific set of functionalities.

Though our approach still requires a lot of effort to be done, and requires more maturity and further evaluations to be applied in production systems, the main advantages with respect to the current state of the art are related to the reusability of the abstract representations of message exchanges for each of the systems involved, as well as the reusability of message filters across different types of applications, what can benefit the agility of developing new added-value applications in the future. Besides, the model is easily extensible and fully declarative, what influences in the lowering of maintenance costs.

CONCLUSION AND FUTURE TRENDS

In this chapter we have motivated the need to use some form of protocol mediation to make it possible to different systems in the logistics domain to communicate successfully with each other, even if they use different protocols (RosettaNet and EDIFACT). Furthermore, we have described the approach for protocol mediation developed in the context of the SWWS project, including the ontology used to describe the choreography (that is, how the systems interact with each other) and the software that implements the component that has been developed.

Though this is a first approach to solve the protocol mediation problem between systems, there is still much work to be done in the future to convert this prototype into a production-quality component. Among them, we have to add new message transfer plugins to allow message transfer using other communication protocols, such as SMTP, FTP, etc., which is what it is used by many of the current systems. Besides, a tighter integration and evaluation with existing systems has to be provided, and a library of common interaction patterns should be also implemented, so that the task of protocol mediation is as simple as possible for those developers that want to develop a mediation solution for their systems.

ACKNOWLEDGMENT

This work was supported by the EU under the SWWS and DIP consortia. In addition we want to thank Stuart Williams, for his ideas that have been the basis for this work and for providing good comments to improve this chapter, to Jorge Pérez Bolaño for making part of the component implementation, to Juan Miguel Gómez for the work on the VSCL ontology, and the other members of the consortium, who contributed to the use case and to the ideas presented here.

Chapter 7.5
Probabilistic Models for the Semantic Web:
A Survey

Livia Predoiu
University of Mannheim, Germany

Heiner Stuckenschmidt
University of Mannheim, Germany

ABSTRACT

Recently, there has been an increasing interest in formalisms for representing uncertain information on the Semantic Web. This interest is triggered by the observation that knowledge on the web is not always crisp and we have to be able to deal with incomplete, inconsistent and vague information. The treatment of this kind of information requires new approaches for knowledge representation and reasoning on the web as existing Semantic Web languages are based on classical logic which is known to be inadequate for representing uncertainty in many cases. While different general approaches for extending Semantic Web languages with the ability to represent uncertainty are explored, we focus our attention on probabilistic approaches. We survey existing proposals for extending semantic web languages or formalisms underlying Semantic Web languages in terms of their expressive power, reasoning capabilities as well as their suitability for supporting typical tasks associated with the Semantic Web.

DOI: 10.4018/978-1-60566-028-8.ch005

INTRODUCTION

The Semantic Web is an extension of the World Wide Web that allows for expressing the semantics and not only the markup of data. By means of the representation of the semantics of data, new and not explicitly stated information can be derived by means of reasoners. In this way, software agents can use and integrate information automatically. As common web languages like (X)HTML and XML are not enough for this purpose (Decker et al., 2000), Semantic Web languages have been standardised (RDF, RDF Schema and OWL), proposed (e.g. WRL, SWRL) and new ones are still being devised. However, most languages that are intended for usage on the Semantic Web are deterministic and cannot represent uncertainty. Currently, there is a growing interest in probabilistic extensions of Semantic Web languages. People start to realize that there is inherently probabilistic knowledge that needs to be represented on the Semantic Web. In the following, we briefly describe five areas where probabilistic information plays a role in the context of the Semantic Web.

Representing inherently uncertain Information: Not all of the information that needs to be represented on the Semantic Web is given in terms of definite statements. E.g. statistical information can provide insights to data to be shared on the Semantic Web. Ontological information attached with statistical values like the percentage of people in a population that are of a certain age can help answer queries about the correlation between this age and a certain chronic disease. There are many situations in which the use of this statistical information could be used to improve the behaviour of intelligent systems. An example would be a recommender System that points the user to certain information based on information about the age group.

Ontology Learning: The manual creation of ontologies has been identified as one of the main bottlenecks on the Semantic Web. In order to overcome this problem several researchers are investigating methods for automatically learning ontologies from texts. Existing approach normally use a combination of NLP and text mining techniques (Maedche & Staab, 2004). Typical tasks are the detection of synonyms and of subclass relations using clustering techniques and association rule mining. In both fields, the result of the mining process can be interpreted in terms of a probabilistic judgement of the correctness of the learned relation.

Document Classification: Document Classification can be seen as a special case of ontology learning called Ontology population. Today a major part of the information on the web is present in terms of documents (Web Pages, PDF Documents etc.). A common way of linking documents to knowledge encoded in ontologies is to assign individual documents to one or more concepts representing its content. Different machine learning techniques have been applied to this problem (Sebastiani, 2002). The most commonly used is the use of naïve Bayes classifiers that estimate the probability of a document belonging to a topic based on the occurrence of terms in sample documents.

Ontology Matching: Different sources often use different ontologies to organize their information. In the case of documents, these are often classified according to different topic hierarchies. In order to be able to access information across these different sources, semantic correspondences between the classes in the corresponding ontologies have to be determined and encoded in mappings that can be used to access information across the sources. Recently, a number of approaches for automatically determining such mappings have been proposed (Euzenat & Shvaiko, 2007). Some of the most successful ones use machine learning techniques to compute the probability that two classes represent the same information.

Ontology Mapping Usage for Information Integration: The usage of the mappings that have been found by matchers as explained in the paragraph above is currently mainly deterministic. Although the mappings are attached with a confidence that expresses how sure the matcher is that the mapping holds, the usage of those mappings consists of a preprocessing step: All mappings that have a confidence value above that threshold are considered deterministically true and all mappings that have a confidence value below that threshold are considered deterministically false. However, there is evidence that this kind of usage is error prone, especially when mappings are composed over several ontologies.

The five examples above clearly demonstrate the importance of probabilistic information in the context of the Semantic Web. E.g., in order to use the learned structures effectively, we need ways to represent and reason about the probabilities assigned to them. Most existing Semantic Web languages are mainly based on classical, deterministic logic and do not support this aspect. In the following, we review a number of general approaches for combining logical languages with probabilistic models and discuss existing proposals for extending semantic web languages with probabilistic information in more details.

Aim and Scope

In this paper, we review existing proposals to extend Semantic Web languages with the capability to handle uncertain information to better deal with the situations mentioned above. There are many ways of representing and dealing with uncertainty. In this paper, we restrict our attention to approaches that use probabilistic methods for representing uncertain information. In particular, we will not cover recent proposals for fuzzy-logic based extensions of semantic web languages. We will also not discuss nonmonotonic and non-standard logics for representing uncertainty unless they are based on a probabilistic semantics. We focus on these approaches, because we believe that probabilistic methods are a natural choice for representing the kinds of uncertainty we often find on the web. A strong motivation is the awareness that Semantic Web technology could greatly benefit from a tighter integration with machine learning and information retrieval techniques which are mostly based on probabilistic models. Probabilities have been criticised mostly due to the fact that people are very bad in providing correct judgements of the probability of events. We think that on the Semantic Web, this argument does not apply, because the aim here is not to use subjective judgements of probability but to provide mechanisms to represent inherently statistical information found on the web or produced by machine learning and matchers. The five examples above clearly demonstrate the importance of probabilistic information in the context of the Semantic Web. In this paper, we review a number of proposals for extending logical languages with probabilistic information in more details. We focus on

1. approaches that directly extend Semantic Web languages, in particular RDF and OWL
2. approaches that extend formalisms that have a very close connection to Semantic Web languages or that have explicitly designed to be used on the Semantic Web by the authors.

In the latter category, on the one hand, we cover probabilistic extensions of Description Logics which are commonly accepted as being the formal basis of OWL. Even though most approaches only cover logics that are much weaker than OWL, the methods proposed can directly be applied to the corresponding subset of OWL. The second kind of languages we consider are rule languages. Although there is not yet an official rule language for the Semantic Web, it is clear, however that rule languages have an important role to play on the Semantic Web. As the area of rule languages is also very broad, we focussed on approaches that have been developed for the Semantic Web. Due to the fact that ontologies and thus Description Logics play a very important role in the Semantic Web, all approaches that extend are that combine rules and ontologies in some way. We restrict ourselves to probabilistic logics that allow combinations of rule and ontologies also with our application example in the area of ontology matching and ontology mapping usage in mind. This application example is presented below.

When talking about the different approaches, we will distinguish between the logical language which is used to describe knowledge and the probabilistic model used to assign probabilities to certain assertions of the logical language. Based on this distinction, we discuss the following issues of the different approaches:

- the general probabilistic model used
- Expressiveness of the logical language
- kind of logical sentences that can be assigned a probability
- reasoning support and expected efficiency for large scale models

In order to evaluate the applicability of the respective approaches, we also consider an example scenario from the area of ontology matching and ontology mapping usage. This example illustrates also the inherent uncertainty of mappings and why this uncertainty needs to be taken into account for reasoning. Our example is based on two ontologies used in the Ontology Alignment Evaluation Challenge[1]. Assume a situation where a user is looking for publications about AI based on two ontologies O_1 and O_2.

Let O_1 be specified by the following axiom which specify that for each publication there is a keyword which is a subject. Furthermore, there is a publication about the Semantic Web which has the keyword Artificial Intelligence.

1. Publication v 8keyword.Subject
2. (SW, AI): keyword
3. SW: Publication

Let O_2 be specified by the following axioms which specify that reports are always publications and every concept in the knowledge base is about some topic. Furthermore, there is one report about Logic Programming and a publication about Description Logics. Both are about Logics.

4. Report v Publication
5. > v 8about.Topic
6. BN:Report
7. DL: Publication
8. (BN, Probability): about
9. (DL, Logics): about

Without loss of generality, we can assume that O_1 is the local ontology, i.e. the ontology being queried explicitly by the user. In order to integrate the information which is stored in both ontologies, mappings are needed. With a probabilistic matcher like GLUE (Doan et al., 2003) mappings can be found which map the second ontology O_2 to our local ontology O_1.

10. O1: Publication(x) ← O2: Publication(x) with probability 0.8
11. O1: Publication(x) ← O2: Report(x) with probability 0.9
12. O1: Subject(x) ← O2: Topic(x) with probability 0.9
13. O1: keyword(x, y) ← O2: about(x, y) with probability 0.8

The mapping (10) basically says that all instances that are belonging to the concept Publication in O_2 are also belonging to the concept publication of O_1 with the probability 0,9. Due to the Kolmogorov axioms of probability theory, the probability that instances belonging to O_2:Publication do not belong to O_1:Publication is 0,1. For completeness, the probability instances that do not belong to O_2:Publication belong to O_1:Publication need to be derived by a matcher as well. GLUE can be modified such that it conforms to this requirement. Let's assume that for (10) this probability is 0.2, for (11) it is 0.4, for (12) it is 0.3 and for (13) it is 0.4.

If we pose a query, we want to get an answer that integrates the information of both ontologies. So, in our example, if we query our local ontology for all publications:

Publication(x) $\wedge$ keyword(x, AI)we want to get also all relevant publications mentioned only in the second ontology. The answer here is

- the publication about Semantic Web with probability 1.0 because it is mentioned in the local ontology and no mapping has been used for deriving it
- the publication about Logic Programming in the second ontology which was derived

by two mappings (10) and (11) and thus gets an accumulated probability of 0,75
- the publication about Description Logics which was derived by only one mapping (10) and has only the probability 0,44

The computation is based on the semantics of the Bayesian Description Logic Programming formalism and shows nicely the importance of the consideration of uncertainty in the area of information integration in the Semantic Web. Without the consideration of the uncertainty each mapping is associated with, all 3 answers would be needed to be treated in the same way although the publication about the Semantic Web is much more relevant than the one about Description Logics. Furthermore, if mapping composition is considered with mapping chains over several ontologies, mappings with rather low probabilities can contribute to an answer with a rather high probability.

Another requirement for a mapping language is the possibility to express mappings between individuals. E.g. in our example, publications of O_2 that are about probabilities are less probable to be publications in O_1 that deal with AI than publications of O1 that are about logics:

14. O1:keyword(x, AI) ← O2: about(x, Probability) e.g. with probability 0.7
15. O1:keyword(x, AI) ← O2: about(x, Logics) e.g. with probability 0.9

It is immediately clear that such mappings need to be expressed for a comprehensive handling of mappings in the Semantic Web area. Mappings that do not involve any variables might also be necessary to be expressed in certain scenarios. When we investigate the different probabilistic extensions of Semantic Web languages, we also have a look at the applicability of the formalisms for the area of Information Integration as presented in this example.

This chapter is structured as follows. In the next section, we present an overview of current Semantic Web languages and related formalisms that are the basis for the logical languages used in the different approaches discussed later in the paper. We also provide a brief introduction to some basic probabilistic models that are used in the different approaches. Based on these basic methods, we discuss proposals for probabilistic languages for the Semantic Web, in the section "probabilistic extensions of Semantic Web languages" below in this chapter. We start with proposals for extending RDF and OWL. Afterwards, we discuss approaches for extending related formalisms with notions of probability, namely Description Logics and different Rule Languages. We conclude the chapter with a critical review of the state of the art and an analysis of directions for future research.

PRELIMINARIES AND BACKGROUND

In this section, we introduce the reader to the state of the art in current Semantic Web languages and the background on the probabilistic models used in the probabilistic extensions surveyed below in the section "probabilistic extensions of Semantic Web languages" below in this chapter.

Current Semantic Web Languages

So far, the development of languages for the Semantic Web was dominated by traditional views on metadata models and logic-based knowledge representation. The major languages that have been developed are RDF/RDF Schema (Lassila & Swick, 1999; Manola & Miller, 2004) for representing metadata and the Web Ontology language OWL (Bechhofer et al., 2004) for representing terminological knowledge in terms of ontologies. The Web Ontology language OWL has its root in the formalism of Description Logics, a decidable subset of first-order logic that contains special constructs for defining classes in terms of necessary and sufficient conditions based on predicates representing binary relations between instances of different classes. More specifically, OWL corresponds to particular Description Logic variants (OWL Lite corresponds to SHIF(D) and OWL DL corresponds to SHOIN(D) (Horrocks et al., 2003)) in the sense that reasoning in OWL can be reduced to checking satisfiability in this logic (Horrocks & Patel-Schneider, 2004). Similarly, the semantics of RDF can be modelled with First-Order Logics, Description Logics and Datalog (Fikes & Guiness, 2001), (de Bruijn & Heymans, 2007).

Recently the need for rule languages on the Semantic Web has been recognized. Rule languages complement Description Logics as they allow to represent kinds of axioms not expressible in SHIF and SHOIN (e.g. property chaining (cf. e.g. (Horrocks, 2005)). Thus, several rule language proposals for the Semantic Web have emerged, examples being the Semantic Web Rule Language SWRL (Horrocks et al., 2005) and the Web Rule Language WRL (Angele et al., 2005) for describing domain-dependent inference rules. The Semantic Web Rule language allows the definition of conjunctive rules over the concepts and binary relations or roles, respectively, which are contained in an OWL ontology (Horrocks et al., 2005). Finally, similar to OWL, WRL is a layered language consisting of three languages, one being a superset of the other. WRL-Core which is the least subset of the WRL language family corresponds to a subset of OWL which lies in the language of Logic Programming (also known as the DLP fragment (Grosof et al., 2003)). WRL-Flight contains WRL-Core and is a Datalog-based rule language. WRL-Full contains WRL-Flight and is a rule language with function symbols and negation under the Well-Founded Semantics (Angele et al., 2005).

Description Logics which is represented by OWL in the Semantic Web and Logic Programming which is represented by a couple of W3C rule language proposals have both nice orthogonal properties and expressivity. Ways for combing both have been and still are investigated. Description Logics and Logic Programming have been found to have a common subset called Description Logic Programs (Grosof et al., 2003). Therefore, Description Logic Programs have a Logic Programming and a Description Logic syntax and wrappers can be used to translate them. Another subset of Description Logics and Logic Programming has been recently proposed that is called Horn-SHIQ (Hustadt et al., 2005) and is a strict superset of Description Logic Programs. Besides the investigation of the intersection of Description Logics and Logic Programming, a lot of research aims at a more comprehensive integration of both formalisms. Several approaches for enabling an interaction between logic programs and description logics exist. Usually, they consist of a Description Logics knowledge base and a Logic Program and the latter is equipped with special features for interacting with the Description Logics knowledge base. An example of such an approach where the Description Logic knowledge is an OWL Lite or OWL DL knowledge base is the formalism of Description Logic Programs under the answer set semantics by (Eiter et. al, 2004).

All of the languages mentioned above are logical languages with a classic model-theoretic semantics that makes a statement either true or false and have no means to represent uncertainty in any way.

Probabilistic Languages and Models

In the following, a short overview of the probabilistic models used for the languages in the sections below is presented. Those models are *Bayesian Networks*, *Bayesian Logic Programs*, *Independent Choice Logic*, *Probabilistic Datalog* and *Multi-Entity Bayesian Networks*. Some of these models are related to each other, e.g. Bayesian Networks can be considered as a subset of Bayesian Logic Programs because the latter provide a compact representation of the former in the same way like first-order logic does with sentential logic. Independent Choice Logic is a generalization and a superset of the formalism of Bayesian Logic Programs. The relationship of Bayesian Networks, Bayesian Logic Programs and Independent choice Logic with probabilistic Datalog is unclear. Multi Entity Bayesian Networks are comprising Bayesian Networks in the same way like Bayesian Logic Programs do. Multi Entity Bayesian Networks are more expressive than Bayesian Logic Programs, but it is unclear whether there is a semantical subset relationship. The relationship between Multi Entity Relationship Programs and Independent Choice Logic has not been investigated yet either. Multi Entity Relationship Programs differ from Probabilistic Datalog by the usage of negation. Probabilistic Datalog uses well-founded negation and the closed world assumption while Multi Entity Relationship Programs model probabilistic First-Order Logic knowledge bases and employ classical negation as well as the open world assumption.

Bayesian Networks (BNs) - One of the best understood models for representing the joint probability distribution of a domain of interest is the model of Bayesian Networks (BNs) (Jensen, 2001). A BN is a compact representation of the joint probability distribution among a set of random variables in a domain under consideration. More precisely, a BN is a directed, acyclic graph with the random variables as nodes and direct influence relationships as arcs. Several exact or approximate algorithms for reasoning in Bayesian Networks exist. Exact inference has been proven to be NP-complete in the maximal number of parents of nodes in the network. A considerable amount of research effort has been spent on different issues like learning of the conditional probability tables/distributions of the nodes in the BN, learning the structure of a BN, etc. (Castillo et al., 1997; Cowell et al., 1999; Jensen, 2001). A BN has been found to correspond to a probabilistic extension of sentential definite clauses.

In the area of the Semantic Web where the same or similar knowledge can happen to be represented on different and independent peers and integrated reasoning and information usage requires mappings, cycles in the complete representation may occur. Unfortunately, BNs are not allowed to have directed cycles. For reasoning with BNs, a huge amount of free and commercial software tools and implementations exist.

Bayesian Logic Programs (BLPs) - Bayesian Logic Programs (Kersting & De Raedt, 2001) are an extension of Bayesian Networks to first-order definite clause logic and a probabilistic extension of definite first-order logic at the same time. A BLP consists of a set of rules and facts, i.e. a definite clause logic program. Each fact is associated with an a-priori probability and each rule with a conditional probability where the probability of the head atom is conditioned on the states of the body atoms. Each ground atom of the Herbrand Model of the definite clause logic program corresponds to a node in a corresponding Bayesian Network. The arcs are defined through the rules. For each valid ground rule, an arc from each node representing a body atom to the node representing the head atom exists in the corresponding Bayesian Network. Additionally, combining rules are defined in order to enable the combination of conditional probabilities of different valid ground rules with the same head atom. BLPs are defined to be acyclic. Therefore, the corresponding Bayesian Networks are acyclic as well. Reasoning with BLPs corresponds to deriving the Herbrand Model or the part of it which is relevant to the query and building the corresponding Bayesian Network. For BLPs, no complexity results have been published, yet. Currently, only one tool for reasoning with BLPs exists: the Balios engine (Kersting & Dick, 2004).

Independent Choice Logic (ICL) - Independent Choice Logic (Poole, 1997) is a logic that is built upon a given base logic that conforms to some restrictions and determines truth in the possible worlds defined by choice spaces. Possible worlds are built by choosing propositions from sets of independent choice alternatives. As base logic, Poole suggests acyclic logic programs under the stable model semantics. However, as we will see later in the subsections on probabilistic (disjunctive) description logic programs below, the approach works for other base logics as well.

An independent choice logic theory on a base logic is a pair (C, F) where C is a so-called choice space and F is a knowledge base in the base logic. C is a set of sets of ground atomic formulae from the language of the base logic such that for two choices $c_1, c_2 \in$ C, if $c_1 \neq c_2$ then $c_1 \cap c_2 = \emptyset$. The elements of C are called alternatives and are basically random variables. The elements of an alternative c are called atomic choices and are basically possible values for the random variable c. The semantics of ICL is defined in terms of possible worlds. A possible world corresponds to the selection of one element from each alternative. Such a selection is called total choice. The atoms that follow using the consequence relation of the base logic from these selected atoms together with the knowledge base of the base logic are true in this possible world. Reasoners for ICL are conceivable but depend on the base logic used. Also, the complexity for deciding consistency and query answering depends on the base logic used.

Multi-Entity Bayesian Networks (MEBNs) - Multi-entity Bayesian Networks (Laskey & Costa, 2005) extend the Bayesian Network model to full First-Order logic. In this way, graphical models with repeated sub-structures can be represented and a probability distribution over models of any consistent, finitely axiomatizable first-order theory can be expressed. With MEBN logic, entities that have attributes and are related to other entities can be represented. Features of entities and relationships among entities are random variables. The knowledge about attributes and relationships is expressed as a collection of MEBN fragments (MFrags) organized into MEBN theories (MTheories). An MFrag represents a conditional probability distribution and an MTheory is a set of MFrags that collectively satisfies consistency constraints ensuring the existence of a unique joint probability distribution over instances of the random variables represented in the MTheory. Possible queries are queries for the degree of belief in specific random variables given evidence random variables. The response to a query is computed by constructing a so-called situation-specific Bayesian Network that can be processed by a usual tool for Bayesian Networks. We are not aware of the existence of general complexity results for reasoning with the MEBN formalism. There are proposals for reasoning algorithms (Laskey, 2006) but no direct implementation of a reasoner for MEBN logic. But there is a translation of a subset of the MEBN formalism into probabilistic relational models implemented in the Quiddity*Suite (cf. http://www.iet.com/quiddity).

Probabilistic Datalog (pDatalog) - Probabilistic Datalog (Fuhr, 2000) is Datalog where each fact and each rule is extended with a probability which states the certainty of it being true. An important underlying assumption is that each element of the probabilistic Datalog program (i.e. every fact and every rule) is probabilistically independent from the other elements. Probabilistic Datalog has been equipped with a well-founded semantics. According to Nottelmann (2005), the probability of a rule can be seen as a conditional probability like with Bayesian Logic Programs. However, while Bayesian Logic Programs allow an arbitrary set of states for the ground atoms in the Herbrand Base, probabilistic Datalog envisions just Boolean states for the atoms. Bayesian Logic Programs do not allow any negation while probabilistic Datalog allows negation under the well-founded semantics. As yet, it is unclear whether probabilistic Datalog programs can be represented as Bayesian Networks. Probabilistic Datalog has been implemented in the HySpirit system (Roellecke et al, 2001) and query answering and the computation of probabilities is a two step process. First, the answers to the Datalog component of the query are computed by means of bottom-up evaluation that employs magic sets. Afterwards, the inclusion-exclusion principle is used to compute the probability of the resulting expressions in Disjunctive Normal Form. (Fuhr, 2000) states "Practical experimentation with HySpirit has shown that the evaluation of about 10 or more conjuncts is not feasible". However, recently, in (De Raedt et. al, 2007) an algorithm has been proposed that is able to perform approximate probabilistic reasoning by combining iterative deepening with binary decision diagrams and is very efficient. (De Raedt et. al, 2007) claims that "one can deal with up to 100000 conjuncts".

PROBABILISTIC EXTENSIONS OF SEMANTIC WEB LANGUAGES

In this section, we survey probabilistic extensions of RDF, RDF Schema and OWL which are W3C recommendations and thus correspond to a standard. We also have a look at probabilistic extensions of subsets of the Description Logics corresponding to OWL, i.e. SHIF(D) and SHOIN(D), and RDF (Schema).

Extensions of RDF

RDF can be considered as the most widely accepted Semantic Web language as it provides the syntactic basis for other Semantic Web languages. A proof for its success is the huge amount of software for processing RDF data that has been implemented up to now. Quite naturally, also some approaches for combining probabilities with RDF have been proposed. Fukushige (2005) proposes an RDF vocabulary for representing Bayesian Networks. In (Udrea et al., 2006), a probabilistic extension of acyclic RDF statements with a model-theoretic semantics and a fixpoint semantics has been proposed. While the first work concentrates on representation issues, the second work can be considered as probabilistic logic on its own.

Representing Probabilistic Information in RDF

In (Fukushige, 2005), a vocabulary extension of RDF has been proposed that is capable of representing the different elements of a Bayesian Network and link them to regular RDF statements. The vocabulary consists of a set of classes (*prob:Partition*, *prob:ProbabilisticStatement*, *prob:Clause*, *prob:Probability*,) and a set of predicates (e.g. *prob:predicate*, *prob:condition*, *prob:case*, *prob:about*) that can represent a Bayesian Network. This vocabulary allows to link statements to their probabilities, express conditional probabilities and more complex probabilistic statements.

Expressiveness
The vocabulary can solely represent Bayesian Networks and can basically be considered as a syntactical interchange format for Bayesian Networks. Thus, as with Bayesian Networks, cyclic probabilistic descriptions cannot be represented. We deem this as a clear disadvantage, because we think that cyclic descriptions cannot be forbidden or avoided in such an open and unstructured environment like the web.

Reasoning and Efficiency
As yet no reasoning support has been implemented. However, after having implemented a parser and wrapper for this vocabulary, in principle any tool for reasoning with Bayesian Networks can be used for reasoning.

Applicability to Information Integration
In principle, the vocabulary can be used for representing mappings between ontologies in a similar way as done with Bayesian Description Logic Programs (see a more detailed presentation on Bayesian Description Logic Programs in the subsection entitled likewise below in this chapter). A huge disadvantage, however, is that Bayesian Networks are not properly integrated with RDF

on the meta level: the vocabulary for representing Bayesian Networks uses RDF for its syntax without a tight coupling to the logical model of RDF. Therefore, RDF ontologies cannot be integrated with mappings expressed in this vocabulary properly. Clearly, with OWL ontologies, it is not possible either.

pRDF

In contrast to the former formalism that is intended to just provide a vocabulary for representing Bayesian Networks, pRDF is a formal probabilistic extension of RDF which corresponds to a of probabilistic logic on its own.

Expressiveness

pRDF is a probabilistic extension of a subset of RDF and consists of a pair (S, I) with S being a pRDF schema and I being a pRDF instance base. A pRDF schema S is defined as a finite set consisting of probabilistic quadruples extending the RDF Schema built-in predicate *rdfs:subClassOf* and non-probabilistic triples using the RDF Schema built-in predicates *rdfs:subPropertyOf*, *rdfs:range* and *rdfs:domain*. This means that in pRDF neither the subproperty relationship nor domain and range restrictions can be defined probabilistically. A pRDF instance base I is a finite set of quadruples extending the RDF built-in *rdf:type* and arbitrary properties $p \in P$.More precisely, pRDF allows the following kinds of probabilistic definitions:

- A sequel of axioms: $C(x) \rightarrow D_1(x), ..., C(x) \rightarrow D_n(x)$ and a probability distribution over the axioms in the sequel where $C \neq D_1 \neq ... \neq D_n$.
- A sequel of axioms: $P(inst, inst_1), ..., P(inst, inst_n)$ and a probability distribution over the axioms in this sequel, where $inst \neq inst_1 \neq ... \neq inst_n$ and P being either the RDF built-in ***rdf:type*** or an arbitrary user-defined property.

Furthermore, the following deterministic expressions are allowed:

- $R(x, y) \rightarrow R_2(x, y)$,
- $R(x, y) \rightarrow C(x)$,
- $R(x, y) \rightarrow C(y)$.

A disadvantage of this approach is that only a very small subset of RDF/S is supported by pRDF yielding a very low expressivity. Furthermore, pRDF instances are required to be acyclic, which again can only be realized in small and closed environments, but not on the Web as it is.

Reasoning and Efficiency

A model theoretic semantics and a fixpoint operator has been defined basing on a t-norm (Fagin, 1999). Furthermore, a reasoner has been implemented that evaluates the fixpoint operator until the least fixpoint has been reached. The properties of a t-norm allow certain pruning strategies that are employed in the reasoning algorithms. Queries to pRDF instances are atomic, i.e. conjunctions cannot be dealt with. A query is a quadruple (*i*, *p*, *S*, *P*) where *i* can be an instance, *p* can be a property, *S* can be a set of instances *i* is related to via *p* and *P* can be a probability distribution for this sequel of property axioms. At most one of the elements of the quadruple is allowed to be a variable.

Unfortunately, for pRDF schema no query answering facility has been defined yet. The reasoning engine supports only reasoning with pRDF instances.

Applicability to Information Integration

This formalism can be used for information integration with mappings. Mappings that map classes from one ontology to classes of the other ontology can be expressed. Also, mappings that map instances from one ontology to instances of another ontology can be expressed. But no mappings can be expressed that capture partly uninstancialized axioms like the ones in (14) and (15). However, the uncertainty attached to each mapping can be used for integrated reasoning with the mappings and the ontologies. But, due to the limited RDF support, not only the mappings but especially also the RDF ontologies which are to be mapped have a very limited expressivity.

Extensions of OWL

Quite naturally a number of proposals for using probabilistic knowledge on the Semantic Web focus on the extension of the Web Ontology Language as the central mechanism of representing complex knowledge in semantic web applications. When looking at the existing proposals, we see two fundamentally different approaches for combining OWL with probabilistic information.

The first kind of approach implements a loose coupling of the underlying semantics of OWL and probabilistic models. In particular these approaches use OWL as a language for talking about probabilistic models. An example of this approach is the work of Yang and Calmet (2006) that propose a minimal OWL ontology for representing random variables and dependencies between random variables with the corresponding conditional probabilities (Yang & Calmet, 2006). This allows the user to write down probabilistic models that correspond to Bayesian networks as instances of the OntoBayes Ontology. The encoding of the model in OWL makes it possible to explicitly link random variables to elements of an OWL ontology, a tighter integration on the formal level, however, is missing. A similar approach is proposed by Costa and Laskey (2006). They propose the PR-OWL model which is an OWL ontology for describing first order probabilistic models (Costa & Laskey, 2006). More specifically, the corresponding ontology models Multi-Entity Bayesian networks (Laskey & Costa, 2005) that define probability distributions over first-order theories in a modular way. Similar to OntoBayes, there is no formal integration of the two representation paradigms as OWL is used for encoding the general structure of Multi-entity Bayesian networks on the meta-level.

The second kind of approaches actually aims at enriching OWL ontologies with probabilistic information to support uncertain reasoning inside OWL ontologies. These approaches are comparable with the work on probabilistic extensions of Description Logics also presented in this section. A survey of the existing work reveals, however, that approaches that directly address OWL as an ontology language are less ambitious with respect to combining logical and probabilistic semantics that the work in the DL area. An example is the work of Holi and Hyvönnen (2006) that describe a framework for representing uncertainty in simple classification hierarchies using Bayesian networks. A slightly more expressive approach called BayesOWL is proposed by Ding and others (Ding et. al, 2006). They also consider Boolean operators as well as disjointedness and equivalence of OWL classes and present an approach for constructing a Bayesian network from class expressions over these constructs. An interesting feature of BayesOWL is some existing work on learning and representing uncertain mappings between different BayesOWL ontologies reported in (Pan et al., 2005) which is an interesting alternative to existing matching tools.

In the following, we discuss PR-OWL and BayesOWL which are the most interesting representatives of the two general approaches to combining OWL and probabilistic models in more details.

PR-OWL

Expressiveness

As mentioned above PR-OWL is an OWL Ontology that describes Multi-Entity Bayesian Networks. OWL is mainly used as a basis for a Protégé plugin for modelling MEBNs and as a language for representing MEBNs and linking them to domain ontologies encoded in OWL. On the other hand, MEBNs can be translated into

Bayesian networks. This means that PR-OWL can be used to link OWL ontologies to Bayesian networks through the MEBN formalism. The Question about the expressiveness of PR-OWL therefore boils down to an analysis of the expressiveness of MEBNs as the actual representation model for uncertainty provided by the approach. According to the authors, MEBNs are capable of representing and reasoning about probabilistic information about any sentence in first-order logic by compiling it into a Bayesian network[2] but they define some restrictions on the nature of the theory, especially on the use of quantifiers. MEBNs specify random variables representing terms and organize them in so-called fragments that describe a certain aspect of the world. Fragments have an interface that defines the terms covered by the fragment. Each fragment defines the joint distribution over the random variables in terms of conditional probabilities encoded as part of a Bayesian network. Variables in terms can be instantiated with multiple constants each instantiation leading to a unique node in the resulting network. Logical formulas are modelled by special fragments that encode the semantics of Boolean operators, quantifiers and instantiation. Fragments are linked via shared terms and additional constraints ensure that only wanted instantiations take place.

It is quite hard to say whether MEBNs are expressive enough to capture probabilistic information about OWL ontologies. In principle it should be possible to translate each OWL ontology into first order logic and assign probabilities to conditional probabilities of the resulting model by encoding it as an MEBN. So far, it has not been investigated whether the restrictions on the use of quantifiers in MEBNs affect the representation of Ontologies. The language should be expressive enough top represent mappings between terms from different ontologies that go beyond simple concept-to concept mappings because it allows to combine terms from different ontologies using arbitrary logical operators as well as the conditional probability of one given the other. It is less clear whether the representation of the mappings can be integrated with the definitions in the semantically consistent way that goes beyond simple reference to parts of the ontologies. In the same way, we could also represent the result of ontology learning methods in terms of conditional probabilities between terms. As fragments in MEBN need input in terms of instantiations of the interface, probabilistic information about instances (e.g. the probability that a paper is about a certain topic) cannot directly be encoded in MEBNs, we could, however find a workaround by explicitly representing a Bayesian classifier as a fragment.

Reasoning and Efficiency

Reasoning in MEBNs is performed by constructing a Bayesian network from the instantiations of fragments. Inside each fragment, a network fragment is created that includes random variables and conditional probabilities for all input objects based on the network pattern specified in the fragment. Here, the actual conditional probability values depend on the number of input objects. The independent network fragments are then combined into a so-called situation-specific network, a Bayesian network that is customized to the given situation in terms of fragments actually instantiated and input objects. The basic reasoning task supported by this network is to compute the probability of one or more random variables given some evidence in terms of instantiations of some input random variables. This means that we can ask for the probability that certain terms are true or false given some knowledge about the truth or falseness of some other terms.

The basic problem of MEBNs when it comes to efficiency is the complexity of the logical language supported. In particular, this has an impact on the size of the situation specific network created as this network represents probabilistic information about all instances simultaneously instead of re-evaluating a standard network multiple times. In information retrieval applications, we often assume that information objects are independent of each other and do not have to be treated in parallel. Although, the bottom-up creation of this network ensures that only the part of the network that is actually needed to answer the query is constructed, this network can still have an infinite size. It would be interesting to identify tractable subsets of MEBNs that correspond to more tractable fragments of first order logic.

Applicability to Information Integration

Again, as with the formalism of Fukushige (2005) presented above, the vocabulary can be used for representing very expressive mappings between ontologies in the MEBN formalism. However, as PR-OWL does not provide a proper integration of the formalism of MEBN and the logical basis of OWL on the meta level, OWL ontologies cannot be integrated with mappings expressed in this vocabulary properly. More specifically, as the connection between a statement in PR-OWL and a statement in OWL is not formalized, it is unclear how to perform the integration of ontologies that contain statements of both formalisms.

BayesOWL

Expressiveness

BayesOWL is an approach for representing probabilistic information about class membership within OWL ontologies. The approach can be seen as an extension of Holi & Hyvönnen (2006). Both approaches support the representation of degrees of overlap between classes in terms of conditional probabilities of the form P(C|D) where C and D are class names. These statements denote the probability that an instance that is a member of D is also a member of C. The main feature of BayesOWL is that it does not only support simple class hierarchies but also class definitions of the following form

- Equivalence: $C(x) \leftrightarrow D(x)$
- Complement: $C(x) \leftrightarrow \neg D(x)$
- Disjointness: $C(x) \rightarrow \neg D(x)$
- Intersection: $C(x) \leftrightarrow D(x) \wedge E(x)$
- Union: $C(x) \leftrightarrow D(x) \vee E(x)$

This means that BayesOWL is actually a probabilistic extension of propositional logic rather than more expressive description logics. This is a quite a strong restriction as it means that we cannot represent probabilistic information about any relations except the subsumption relation. This limits the applicability to scenarios where we are only interested in the classification of information objects and not in relations between them. This means that the approach is not suitable to support the reasoning about structured information which plays an important role in many semantic web applications.

Reasoning and Efficiency

The basic reasoning task associated to BayesOWL is given some evidence for an object in terms of its classification to determine membership probabilities for all the classes in the ontology. For this purpose a Bayesian network is constructed from the definitions in the model. As in PR-OWL network nodes with a predefined conditional probability table are used to represent Boolean Operators. This computation is done using iterative proportional fitting, a special technique from statistics that selects a probability distribution that best fits the conditional probabilities given in the network. This approach is quite different from the other approaches presented in this survey as the inference is not guided by a specific query. This can be an advantage if many queries about different aspects of the model are issued; we can expect it to be unnecessarily complex if we are only interested in very specific aspects of the model as the method will also compute probabilities that do not have an influence on the variable. Despite this fact, the use of Bayesian networks for implanting probabilistic reasoning can be expected to be relatively efficient. A special feature of BayesOWL is that it allows including probabilistic mappings between different ontologies into the inference procedure (Pan et al., 2005). Mappings are represented in terms of conditional probability statements that include concepts from different ontologies. The probabilistic influence of these statements on the distributions is used to update the distribution in the mapped ontologies. The conditional probabilities used in the mappings can be created using statistical learning methods.

In summary, the approach is well suited for applications that use rather simple classifications of information items such as documents that are classified according to a topic hierarchy. It supports the representation and semi-automated mapping of such hierarchies. As soon as the application demands for more structural information such as document metadata, the approach reaches it limits in terms of the inability to represent information about relations.

Applicability to Information Integration

This formalism provides an integration between Bayesian Networks and OWL and thus it can be used for expressing uncertain mappings between OWL ontologies and for using those mappings for integrating the information distributed over the ontologies. As only class definitions are supported, however, neither the mappings nor the ontologies themselves can contain instances which is a severe drawback of this approach. Also, the expressivity on the schema level is very low in general and thus only a very small subset of OWL can be used for expressing ontologies to be mapped (and mappings).

Extensions of Description Logics

There have been a number of approaches for extending description logics with probabilistic information in the earlier days of description logics. Heinsohn (Heinsohn, 1991) was one of the first to propose a probabilistic notion of subsumption for the logic ALC. Jaeger (Jaeger, 1994) investigated some general problems connected with the extension of T-Boxes and A-Boxes with objective and subjective probabilities and proposed a general method for reasoning with probabilistic information in terms of probability intervals attached to Description logic axioms. Recently, Giugno and Lukasiewicz proposed a probabilistic extension of the logic SHOQ along the lines sketched by Jäger (Giugno & Lukasiewicz, 2002). A major advantage of this approach is the integrated treatment of probabilistic information about Conceptual and Instance knowledge based on the use of nominals in terminological axioms that can be used to model uncertain information about instances and relations. An alternative way of combining description logics with probabilistic information has been proposed by Koller et al. (1997). In contrast to the approaches mentioned above, the P-CLASSIC approach is not based on probability intervals. Instead it uses a complete specification of the probability distribution in terms of a Bayesian network which nodes correspond to concept expressions in the CLASSIC description logic. Bayesian networks have also been used in connection with less expressive logics such as TDL (Yelland, 2000). The approaches for encoding probabilities in concept hierarchies using Bayesian networks described in the section “preliminaries and background” can be seen as a simple special case of these approaches.

We can see two general approaches for extending description logics with probabilistic information. The first is based on probability intervals describing the validity of concept inclusion axioms, the other one is based on the use of Bayesian networks for assessing and relating the probability of different features of the terminological model. In the following, we will restrict our discussion to representative approaches of these different strategies, namely P-SHOQ and P-CLASSIC.

P-SHOQ(D)

Expressiveness

P-SHOQ(D) is based on the description logics SHOQ(D) which is very close to the description logic which provides the semantics of OWL. The only feature of OWL that is not contained in the language is the use of inverse roles. In particular, the language also supports datatypes in the same way as OWL does. Probabilistic information is represented by statements of the form (C|D)[l,u] where C and D are concept expressions in SHOQ(D) and l and u are the maximal and the minimal probability that an instance of D is also an instance of C. Using this general scheme, different kinds of knowledge can be represented, for instance:

1. The probability that C is subsumed by D P(C(x)|D(x))
2. The probability that a particular individual o is a member of a concept C P(C(o))
3. The probability that an individual o is related to an instance of a concept C P(R(o,x)|C(x))
4. The probability that two individuals o and o' are related P(R(o,o'))

From a representational point of view, P-SHOQ(D) offers a lot of possibilities for supporting the task mentioned in the motivation. For the case of overlapping ontologies uncertain mappings between concepts in different ontologies can be represented using probabilistic subsumption statements of the form P(i:C(x)| j:D(x)) where C is a concept from ontology i and D a concept from ontology j. Concerning the task of ontology learning, the language is expressive enough to capture typical information that is determined in the learning process such as the concept hierarchy. We can also represent uncertain information about the range of concepts. The lack of inverse relations in the language, however, makes it impossible to represent domain restrictions. The use of nominals allows us to represent the results of instance learning both for concept and relation instances using statement 3 and 4 mentioned above.

Reasoning and Efficiency

Reasoning in P-SHOQ is based on a function μ that maps every instance of the interpretation domain Δ on a number in [0,1] such that the value of this function for all elements in Δ sum up to 1. The Probability Pr(C) of a concept expression C is defined as the sum of all μ values of the instances of C. Based on this semantics a number of reasoning task have been defined that can be solved using appropriate inference procedures. At the most basic level, the tasks supported by the language are to determine whether a given knowledge base is consistent and to compute the upper and lower bounds l and u of a conditional probability statement P(C(x)|D(x))∈[l,u]. Computing these bounds in based on independent choice logic. Different choices are specified by the possible semantic relations that could hold between any pair of concepts. This definition of choices leads to two linear equation systems whose solutions are the upper and the lower bound of the probability. Solving the equation system involves reasoning in SHOQ(D) for determining the possible choices.

Based on this general method for computing upper and lower bounds a number of reasoning tasks that generalize standard reasoning tasks in Description Logics can be defined. In particular, the approach supports the following tasks

- **Concept satisfiability:** in particular decide whether P(∃x:C(x))∈[0,0] does not follow
- **Concept Subsumption:** given two concepts C and D compute l and u such that P(C|D)∈[l,u] follows from the knowledge base
- **Concept Membership:** given an instance o and a concept C compute l and u such that P(C(o))∈ [l,u] follows from the knowledge base.
- **Role Membership:** given two instances o and o' and a relation R compute l and u such that P(R(o,o'))∈[l,u] follows from the knowledge base

These reasoning tasks provide a suitable basis for supporting tasks such as probabilistic data retrieval across different ontologies. In particular, we can formulate queries as concept expressions in SHOQ(D) and compute the probabilities that certain instances are members of this query concept. Probabilistic information originating from uncertain mappings and classifications provide background constraints for this reasoning task. A potential problem of the approach with respect to the retrieval scenario is the ability to use the probabilities as a basis for ranking. As the approach is based on intervals rather than exact probabilities, there is no total order on the results that could be used for this purpose. Another potential problem is the complexity of the approach which has not been investigated in detailed. It is clear however, that reasoning in SHOQ(D) is likely to be highly intractable.

Applicability to Information Integration

P-SHOQ can be used for expressing all the mappings mentioned in the introduction. The ontologies, however, are not allowed to contain inverse roles. Furthermore, RDF ontologies whose semantics cannot be described solely with the Description Logics paradigm cannot be integrated, because the Logic Programming paradigm which is needed for describing the RDF semantics as well, is not covered by P-SHOQ.

P-CLASSIC

Expressiveness

P-CLASSIC is a probabilistic extension of the CLASSIC Description Logics. Different from SHOQ, the CLASSIC description logics is designed for efficiency of reasoning rather that for expressive power. In particular, CLASSIC does only contain conjunction, negation on atomic concepts, universal and number restrictions as well as role fillers. As a result, deciding subsumption in CLASSIC can be computed in polynomial time based on structural comparison of concept expressions. P-CLASSIC extends the language with probabilistic information about properties of typical instances in terms of a Bayesian network. The corresponding network contains random variables indicating the following information.

- Membership in atomic concepts A
- For each Property R
    - A distribution over possible fillers o in expressions of the form P(R(x,o))
    - A distribution over possible ranges C in expressions of the form $(R(x,y) \rightarrow C(y))$ where C is specified in terms of a separate Bayesian network.
    - A distribution over the number of fillers n in equations of the from $(\exists^{=n} y{:}R(x,y))$

Additionally, the network represents an efficient encoding of the joint probability over these random variables in terms of conditional probabilities between kinds of assertions mentioned above. This means that P-CLASSIC can be used to represent probabilistic information about terminological knowledge. In particular, we can represent probabilistic subsumption relations between atomic concepts that can be used to represent uncertain mappings and the results of learning subsumption relations. The other features of the language can also be used to represent the result of ontology learning especially distributions over property fillers and ranges are useful for this purpose.

Reasoning and Efficiency

The basic reasoning service in P-CLASSIC is to compute the probability of a complex concept expression based on the definition of the joint probability distribution over atomic classes and features of relations. The inference algorithm given in (Koller et al., 1997) takes a concept expression and a P-CLASSIC knowledge base as input and returns the probability of the concept expression.

This probability is computed by bottom-up construction of a Bayesian network that represents the concept and using it to infer the probability that an arbitrary object is member of this concept expression. This method can be used to implement probabilistic data retrieval by computing the probability of a class description using a Bayesian network that has been initialized with evidence that corresponds to the properties of the individual we want to test. The fact that P-CLASSIC is based on exact probabilities rather than probability intervals means that the probability defines a natural ranking function for answers.

The major advantage of P-CLASSIC is the fact that reasoning is relatively efficient compared to other formalisms. This is due to the fact that both, the logical and probabilistic formalism have been chosen with efficiency in mind. The algorithm for constructing the Bayesian Network of a class description is defined as a direct extension of the structural subsumption algorithm of P-CLASSIC that is known to be polynomial. Additional complexity is added by the need to evaluate the network. This problem is known to have an exponential complexity, but only in the maximal the number of parents of a node. Further, the reuse of results for certain class expressions improve the time needed for actually compute the probability. This means that P-CLASSIC has relatively nice properties with respect to the computational complexity.

Applicability to Information Integration

When P-CLASSIC was devised, its application in the area of information integration was not intended. Mainly, it was intended to express and reason about the degree of overlap between concepts of an ontology. P-CLASSIC works with probabilistic formalizations of so-called p-classes each of which describes a certain class of individuals. Except of the expressibility of a the probability distribution over the role fillers of a role, the probabilistic expressions formalize concepts. The possibility to express a probability distribution over the role fillers of a role is not enough for the area of information integration. Therefore, this formalism is too restricted for being used in the area of information integration.

Extensions of Logic Programming Formalisms

Several approaches for extending Logic Programming formalisms with probabilities have been proposed. However, most of them have not been designed with the Semantic Web in mind. In the following, we discuss only those probabilistic logic programming approaches that have been designed for the Semantic Web and involve ideas about how to connect rule bases with ontologies represented in OWL or related formalisms. Two kinds of such approaches can be distinguished. The first kind integrates OWL with Logic Programming by allowing to specify a logic program and a description logics knowledge base at the same time and allowing them to interact in some way. In general, the logic program is used for querying both knowledge bases. For this purpose, the logic program can contain atoms that query the Description Logics knowledge base. We survey two approaches of this kind, (Lukasiewicz, 2005) (and a restricted version thereof by Lukasiewicz (2006)) and (Cali et al, 2008). The other kind of approaches base on a subset OWL and Logic Programming have in common and on a translation from OWL to Logic Programming formalisms that have been extended with probabilities. The subset of OWL and Logic Programming, that these approaches consider is Description Logic Programs (DLP) which is very close to Datalog (Grosof et al., 2003). (Predoiu, 2006; Predoiu & Stuckenschmidt, 2007) translates OWL ontologies that lie in the DLP fragment to a probabilistic Datalog formalism that is close to Bayesian Logic Programs (Kersting & De Raedt, 2001) while (Nottelmann & Fuhr, 2005) translate a slight extension of the DLP fragment, namely DLP with equality, to probabilistic Datalog (Fuhr, 2000).

In the following, we present a short overview on Description Logic Programs: As they are a subset of the Description Logics underlying OWL and the Logic Programming paradigm and thus have a Description Logics and a Logic Programming syntax. In the logic programming syntax, they correspond to pure Datalog without negation, equality and integrity constraints. I.e. as with Datalog, a Description Logic Program consists of facts and rules. Each rule has the form $H \leftarrow B_1, ..., B_n$, where H and the B_i are atomic formulae and $n \geq 1$. An atomic formula consists of a predicate symbol *p* followed by a bracketed n-tuple of terms ti, $p(t_1, . . ., t_n)$ with $n \geq i \geq 0$. A term can be either a constant (i.e. an instance) or a variable (i.e. a placeholder for an instance). If all terms in an atomic formula are constants, the atomic formula is called a ground atom. The left hand side of a rule, H, is called head and the right-hand side of a rule, $B_1 \wedge . . . \wedge B_m$, is called body. All variables in rules are universally quantified, although this is not explicitly written. For i = 0, the rule is called a fact. Only ground atoms are allowed in facts.

In the DLP language, the predicates are only allowed to be 2-ary and the variable graph of the body of each rule is connected and acyclic. Semantically, Description Logic Programs in the logic programming syntax do not differ from them having been specified in the description logics syntax. As reasoning is concerned with syntactical manipulations, however, Description Logic Programs in the logic programming syntax are restricted to fact-form inference with logic programming reasoners, i.e. only facts can be derived and no axioms like with description logics reasoners that reason with the description logics syntax of Description Logic Programs.

In the following we compare two formalisms that are based on the Description Logic Programming fragment and 2 formalisms that are more expressive.

Bayesian Description Logic Programs

In (Predoiu, 2006), Description Logic Programs have been embedded into the Bayesian Logic Programming formalism (Kersting & De Raedt, 2001). In this approach, the probabilistic extension has the purpose of information integration and has been proposed in order to represent uncertain mappings between ontologies and rules. Also, a means to reason with the mappings and the ontologies and rules having been mapped in an integrated way has been proposed.

Expressiveness

Bayesian Description Logic Programs (BDLPs) are a probabilistic extension of the logic programming syntax (and semantics) of Description Logic Programs (Grosof et al., 2003). In Bayesian Description Logic Programs, facts are attached with an apriori probability and rules are attached with a conditional probability where the states of the head atom are conditioned on the states of the body atoms. Like a Bayesian Logic Program, a Bayesian Description Logic Program encodes a Bayesian Network.

Reasoning and Efficiency

The basic reasoning task associated with Bayesian Description Programs is querying for the probability density of a conjunction of ground atoms given a conjunction of ground evidence atoms. In (Predoiu & Stuckenschmidt, 2007), the semantics has been extended to allow non-ground query atoms in order to enable information retrieval by deriving all ground atoms that satisfy the query and rank them by means of their probabilities. There are no complexity results known yet for Bayesian Description Logic Programs and no inference engine is available yet. However, the inference engine for Bayesian Logic Programs, Balios (Kersting & Dick, 2004) which calls Sicstus Prolog for deriving the least Herbrand Model, can be used for reasoning with Bayesian Description Logic programs as well, because Bayesian Description Logic Programs are a subset of Bayesian Logic Programs.

Applicability for Information Integration
Bayesian Description Logic Programs have been devised in order to enable Information Integration and they are able to cover all representational issues mentioned in the introduction. However, the ontologies to be mapped are restricted to the Description Logic Programming fragment and this is often a too severe expressivity restriction.

pOWL Lite$^-$ and pOWL Lite^{EQ}

(Nottelmann & Fuhr, 2005) have presented probabilistic extensions of two OWL Lite subsets. One of these subsets corresponds to Description Logic Programs and the other one to Description Logic Programs with equality. The probabilistic extensions are both based on probabilistic Datalog (c.f. the section on probabilistic models above in this chapter). OWL formulae that can be translated to Datalog can each be provided with probabilities and processed afterwards by a pDatalog system.

Expressiveness
As mentioned above, two OWL Lite subsets have been extended with probabilities. One corresponds to Description Logic Programs, its probabilistic extension being called pOWL Lite$^-$.[3] The other one corresponds to Description Logic Programs extended with equality, its probabilistic extension being called pOWL Lite^{EQ}. A translation of OWL formulae in the Description Logic Programming fragment (possibly with equality) into the Logic Programming syntax is provided and these can be attached with probabilities in the way that pDatalog allows. These probabilistic Datalog rules are processed afterwards by a pDatalog system.

Possible pOWL Lite$^-$ expressions are listed below. Note that α (α ∈ [0, 1]) which is written in front of each uncertain expression is the probability for the complete expression which is written behind it.

- **Class membership axioms:** α C(a) with α ∈ [0, 1]

This expression corresponds to the statement that a is an instance of class C with probability α

- **Complex class membership assertions:** α C(y) ← R(a, y)
- **Role assertions:** α R(a, b)
- **class inclusions:** α_1 B_1(x) ← A(x). and **…** and α_n B_n(x) ← A(x). with n ≥ 1. This expression corresponds to the OWL expression Class(A partial B_1 … B_n) and its probabilistic extension allows to express for each B_i a certainty with which A is a subclass of B_i.
- **Class inclusions with a restriction:** α B(y) ← A(x), R(x, y). This expression corresponds to the OWL expression Class(A partial restriction(R allValuesFrom B)) and its probabilistic extension allows to express the probability for A being a subclass of the class of elements that have a relation with elements of B.
- **Role inclusions:** α R(x, y) ← S(x, y).
- **Symmetric role axioms:** α R(x, y) ← R(y, x).
- **Transitive role axioms:** α R(x, z) ← R(x, y), R(y, z).
- **Domain restrictions:** α B(x) ← R(x, y).
- **Range restrictions:** α B(y) ← R(x, y).

Additionally, OWL Lite^{EQ} allows the expression of the following axioms:

- **Individual equivalence expressions:** α a = b ← U(a), U(b).
- **Maximal Cardinality of 1 expressions:** α y = z ← A(x), R(x, y), R(x, z).
- **Functional role axioms:** α y = z ← R(x, y), R(x, z).
- **Inverse functional role axioms:** α x = y

$\leftarrow$ R(x, z), R(y, z).

Y is a predicate which contains all individuals that are available in the pOWL Lite$^-$ or pOWL Lite^{EQ} knowledge base.

Additionally, in order to deal with pOWL Lite$^-$/ pOWL Lite^{EQ} more easily, a language for stating probabilistic horn rules basing on the SWRL syntax has been added. For the purpose of reasoning, however, this language is translated to pDatalog as well. Clearly, with this addition, the expressivity goes beyond Description Logic Programs. Although the supported fragment of OWL is not extended, much more of the Logic Programming fragment is covered. It is unclear whether full pDatalog or only a subset is supported.

Reasoning and Efficiency

In (Nottelmann & Fuhr, 2005), an implementation, i.e. a wrapper for a pDatalog reasoner like HySpirit, has not been provided. Efficiency for reasoning with pOWLLite$^-$ and pOWLLite^{EQ} can be considered promising due to its limited expressivity. However, with the addition of the capability for stating horn rules basing of the SWRL syntax, one might end up with the full expressivity of pDatalog. Then, the general empirical complexity results of pDatalog mentioned in the section "probabilistic languages and models" above in this chapter is carried forward to pOWLLite$^-$ and pOWLLite^{EQ} with the addition of probabilistic horn rules in the SWRL syntax.

Applicability for Information Integration

This formalism is applicable for information integration and can express all kinds of mappings suggested in the introduction. But again, the restriction of the ontologies to the Description Logic Programming fragment is often too severe. Note that, although the formalism has been additionally equipped with horn rules basing on the SWRL syntax, the integration with the translation of the OWL ontologies in the DLP fragment has not been formalized explicitly and thus cannot be considered concerning the expressivity of the ontologies.

Probabilistic Description Logic Programs with Special DL-Atoms

In (Lukasiewicz, 2005) and (Lukasiewicz, 2006), probabilistic description logic programs[4] (pdl programs) are presented that base on a loose query-based coupling of a Logic Program and a Description Logic knowledge base. The non-probabilistic formalism that pdl programs are based on has been published in (Eiter et al., 2004) as a combination of answer set programming with Description Logics. This non-probabilistic formalism has been combined with independent choice logic yielding a probabilistic extension of the base formalism.

Expressiveness

By means of the non-probabilistic base logic, a knowledge base KB = (*L*, *P*) can be specified. *L* corresponds to a classical SHIF(D) or SHOIN(D) knowledge base and *P* corresponds to a Logic Program which may contain queries to *L*. While *L* can be specified in the typical Description Logics syntax and has the typical Description Logics semantics, the Logic Program consists of a finite set of rules of the form

$$a \leftarrow b_1, ..., b_k, \text{not } b_{k+1}, ..., \text{not } b_m \text{ with } m \geq k \geq 0.$$

Here, a and the b_i are atomic formulae. An atomic formula consists of a predicate symbol *p* followed by a bracketed n-tuple of terms ti, p(t_1, . . ., t_n) with n ≥ i ≥ 0. A term can be either a constant (i.e. an instance) or a variable (i.e. a placeholder for an instance). Two kinds of negated atoms are distinguished: classically negated atoms ¬*a* and default-negated atoms *not a*. Furthermore, there are special kinds of atoms called dl-atoms that are allowed to be one of the $_{bi}$ with k ≥ i. I.e. the dl-atoms are only allowed to occur in the positive, unnegated part of the body . Such dl-atoms form a query to *L* with additional constraints that extend or shrink the instance set associated with concepts and roles occurring in L. The logic program *P* has been given a well-founded and an answer-set semantics in (Eiter et. al, 2004).

Basing on this formalism, in (Lukasiewicz, 2005) and (Lukasiewicz, 2006), a probabilistic extension has been proposed that combines this formalism with independent choice logic. A probabilistic description logic program is a knowledge base KB = (L, P, C, μ) where

- (L, P) is a dl program as explained above. Note that in (Lukasiewicz, 2005), a well-founded and an answer-set semantics have been defined for *P*.
- *C* is a choice space that corresponds to a set of sets whose union is a subset of the Herbrand Base HB_P of *P*. Alternatives, atomic choices and total choices are defined analogously to independent choice logic (c.f. the section "probabilistic languages and models" above in this chapter). No atomic choice is allowed to occur in the head of rule in *P*, but in anywhere in the body.
- μ is a probability distribution on the choice space C, i.e. μ: $\cup C \rightarrow [0, 1]$ such that $\Sigma_{a \in A} \mu(a) = 1$ for all alternatives $A \in C$ and $\mu(B) = \Pi_{b \in B} \mu(b)$ for all total choices B of C. Note that the probability of total choices imposes probabilistic independence between the alternatives of C or, differently worded, the random variables specified by C.

Reasoning and Efficiency

Probabilistic queries to a pulp knowledge base as specified above can be either atomic or complex:

1. an atomic probabilistic query queries for the probability of a formula ψ given another formula ϕ: $(\psi \mid \phi)[l, u]$. Here, l, u are placeholders for reels in the interval [0, 1] and stand for the lower bound and the upper bound of the probability. Formulas can be arbitrary contain of negation and conjunction.
2. (complex) probabilistic queries F are inductively defined as follows: each atomic probabilistic query A (with l, u being instatiated, however) is a probabilistic query. If G and H are probabilistic queries, then so are $\neg G$ and $G \wedge H$.

The correct answer to a complex probabilistic query F is defined to be the set of all substitutions θ such that $F\theta$ is a consequence of the knowledge base. With the answer set semantics, it is distinguished between answer set consequences and tight answer set consequences. For answer set consequences, every model of the knowledge base has to be a model of $F\theta$ as well. For tight answer set consequences, furthermore, *l* (resp. *u*) have to be the infimum (resp. supremum) of $Pr(\psi\theta \mid \phi\theta)$ subject to all models of KB given that $Pr(\phi\theta) > 0$.

With the well-founded semantics, $F\theta$ is a consequence of KB if $F\theta$ is true in the well-founded model. Again, a query $(\psi \mid \phi)[l, u]\theta$ is a tight well-founded answer, is *l* (resp. *u*) are the infimum (resp. supremum) of $Pr(\psi\theta \mid \phi\theta)$ given that $pr(\phi\theta) > 0$. Note that $Pr(\psi\theta \mid \phi\theta)$ is a probabilistic interpretation either under the answer-set semantics or under the well-founded semantics as defined in (Lukasiewicz, 2005), depending on the context. More specifically, Pr is a probabilistic distribution over all models.

The computation of tight answers to queries $(\psi \mid \phi)[L, U]\theta$ under the answer-set semantics involves classical logical deduction (according to the semantics used) and solving two linear optimization problems. The complexity of solving these linear optimization problems has not been discussed, yet. However, deduction under the answer set semantics has a very high complexity. More specifically, for *L* being a SHIF(D) knowledge base (resp. a SHOIN(D) knowledge base) query answering is in the complexity class co-NEXP (resp. co-NP^{NEXP}) (Eiter et. al, 2004). Query answering under the well-founded semantics is for L being a SHIF(D) knowledge base (resp. SHOIN(D) knowledge base) complete for EXP (resp. P^{NEXP}) (Eiter et. al, 2004). In (Lukasiewicz, 2006), for the same syntax as shown above for both, knowledge bases and queries, a stratified semantics based on a (local) stratification of the knowledge base has been defined. Complexity for this semantics has not been considered at all. However, query answering in stratified logic programs in general, i.e. without integrating Description Logic knowledge bases, has a much lower complexity than in those that go beyond stratification and lie in the well-founded semantics, but is still intractable in the worst case.

Applicability to Information Integration

This formalism is the first one mentioned in this chapter that is able to fully integrate full OWL and a huge part of RDF. Concerning the expressivity, this formalism is therefore very suitable for the representation of OWL (i.e. the OWL-Lite and OWL-DL fragments) and a huge part of RDF in the same syntax. However, as dl-atoms are not allowed to occur in the head of the rules, only a Logic Program can be the target of a mapping. Therefore, it cannot be used for information integration on the Semantic Web where OWL ontologies can be the target of mappings.

Probabilistic Disjunctive Description Logic Programs

In (Cali et al., 2008), a tighter integration of Logic Programs and the Description Logics underlying OWL has been combined with independent choice logic. This approach is called probabilistic disjunctive description logic programs (pddl programs) and differs from the formalism mentioned above in the fact that there are no special dl-atoms necessary for the flow of information between *L* and *P*. In fact, concepts and roles of L can occur as unary or binary predicates in P as well. Furthermore, the logic programming component *P* is allowed to have rules with disjunction in the head while with probabilistic description logic programs with special DL-atoms mentioned above, *P* was only allowed to consist of rules with a single, positive atom in the head[5]. Note also that classical negation is not allowed to occur in probabilistic disjunctive description logic programs in contrast to probabilistic description logic programs with special dl-atoms described above.

Expressiveness

As before, in the section above, a non-probabilistic base logic is combined with independent choice logic yielding probabilistic disjunctive description logic programs. The non-probabilistic logic used is disjunctive description logic programs (Lukasiewicz, 2007). It allows to specify a knowledge base KB = (*L*, *P*) with *L* being either a SHIQ(D) or a SHOIN(D) knowledge base and *P* being a logic program. *P* is a finite set of disjunctive rules of the form

$$\alpha_1 \vee \ldots \vee \alpha_k \leftarrow \beta_1, \ldots, \beta_n, \text{not } \beta_{n+1}, \ldots, \text{not } \beta_{n+m}$$

with $\alpha_1, \ldots, \alpha_k, \beta_1, \ldots, \beta_{n+m}$ being atoms built with the predicate, role and concept symbols of *P* an *L* in the usual way. The logic program *P* has been given an answer set semantics in (Lukasiewicz, 2007).

Basing on this formalism, in (Cali et. al, 2008), a probabilistic extension has been proposed that combines this formalism with independent choice logic. A pddl program is a knowledge base KB = (L, P, C, μ) where

- (*L*, *P*) is a ddl program as explained above
- *C* is a choice space that corresponds to a set of sets whose union of its elements A $\in$ C corresponds to a subset of the set $HB_P \setminus DL_P$. Here, HB_P is the Herbrand base of *P* and DL_P is the subset of the Herbrand base

of *P* that is built with predicates that occur in *L* as concepts or roles, too. Alternatives, atomic choices and total choices are defined analogously to independent choice logic (c.f. the section "probabilistic languages and models" above in this chapter).

- μ is a probability distribution on the choice space C as defined in the section above.

Reasoning and Efficiency

A probabilistic query to a pddl knowledge base has the form $\exists\ (c_1(\mathbf{x}) \vee \ldots \vee c_n(\mathbf{x}))[r, s]$ where **x**, r, s are tuples of variables, $n \geq 1$, and each $c_i(\mathbf{x})$ is a conjunction of atoms constructed from predicate and constant symbols in P and variables in **x**. Similarly to probabilistic description logic programs with special dl-atoms, it is distinguished between correct and tight answers to such a query. Given a probabilistic query $\exists\ (q(\mathbf{x}))[r, s]$, a formula $(q(\mathbf{x}))[l, u]$ with $l, u \in [0, 1]$ is a *correct consequence* of the knowledge base iff the probability of it lies always in the interval [0, 1] for every answer set of KB and every variable assignment σ. A formula $(q(\mathbf{x}))[l, u]$ with $l, u \in [0, 1]$ is a *tight consequence* of the knowledge base iff l (resp. u) is the infimum (resp. supremum) of the probability of the formula subject to all answer sets of the knowledge base and all variable assignments σ.

The consistency and the query processing problem are decidable in pddl programs. For a pddl knowledge base KB = (*L*, *P*, *C*, μ) with *L* being either a SHIF(D) or a SHOIN(D) knowledge base, deciding whether KB is consistent is complete for $NEXP^{NP}$ given that the size of C is bounded by a constant. For a pddl knowledge base KB = (*L*, *P*, *C*, μ) with *L* being either a SHIF(D) or SHOIN(D) knowledge base, deciding whether (q)[l, u] with q being a ground atom from HB_P and $l,u \in [0, 1]$ is a consequence of KB is complete for co-$NEXP^{NP}$.

In (Cali et al, 2008), a subset of pddl knowledge bases with strictly limited expressivity has been presented which allows for deciding consistency and query processing in polynomial time. However, for this purpose, the Description Logics part *L* must be in DL-Lite (Calvanese et. al, 2005) and the logic programming part *P* extended with additional rules modelling basic inclusion in *L* must be normal, i.e. only one non-negated atom in the head is allowed, and locally stratified.

Applicability to Information Integration

This formalism is capable of representing full OWL (i.e. full OWL-Lite and OWL-DL ontologies) and a huge part of RDF in the same syntax and is therefore capable for integrated query answering and reasoning with both formalisms. Furthermore, as predicates representing concepts and roles in the ontology can occur freely in the rule, i.e. also in the head, mappings can be represented with the formalism straightforwardly. Furthermore, as disjunction in the head is allowed, inconsistent mappings can be dealt with more easily that with pure horn rules that allow only one atom in the head of a rule. The representation of mappings with this formalism has been investigated and described in detail by Cali & Lukasiewicz (2007).

DISCUSSION AND CONCLUSION

We conclude the chapter with a discussion of the benefits and drawbacks of the different approaches for extending Semantic Web languages with probabilistic information that we have surveyed above. It turns out that there exist *two different kinds of probabilistic extensions*. The first kind of extensions is a rather loose coupling between an existing Semantic Web language and a probabilistic model. There, the Semantic Web Language is just used syntactically as a vocabulary for exchanging knowledge bases specified in the probabilistic model. The second kind of extensions provides a tight integration on the formal level between a Semantic Web Language or a subset of it and a probabilistic model. The second kind of extensions encompasses as well the formalisms that integrate a Semantic Web language with logic programming and combine the resulting formalisms with a probabilistic model. These extensions provide also a tight formal integration of a Semantic Web language which usually is OWL-Lite/OWL-DL or the Description Logic which underlies these OWL fragments with a logic programming formalism and a probabilistic model.Extensions of the first kind that are mentioned in this survey are the approaches of

- (Fukushige, 2005) which proposes a vocabulary for encoding Bayesian Networks with RDF,
- (Yang & Calmet, 2006) which proposes a vocabulary for encoding Bayesian Networks with OWL and
- (Costa & Laskey, 2006) which proposes a vocabulary for encoding Multi-Entity Bayesian Networks with OWL.

These approaches are rather unsatisfying because they do not consider the semantics of Semantic Web languages but rather focus at a special kind of probabilistic model, i.e. Bayesian Networks or Multi-Entity Bayesian Networks, and provide a Semantic Web based syntactical interchange format for these probabilistic models and their semantics. By means of these approaches uncertainty can only be represented on the Semantic Web but no Semantic Web statement is extended by some kind of uncertainty. Thus, from the five areas mentioned in the introduction where a consideration of uncertainty is needed on the Semantic Web, only the needs of the first area are met. I.e. only the requirements for representing statistical information are met. The area of the Semantic Web itself does not benefit substantially from these extensions. It is even arguable whether the probabilistic models represented benefit from using a vocabulary basing on a Semantic Web language without any formal integration. Note that currently no reasoning support for these vocabularies has been implemented yet, i.e. no wrappers exist that is able to parse the Semantic Web language vocabulary defined for the particular probabilistic models and feed it to a reasoner that is capable to deal with them. However, for PR-OWL, a reasoner implementation effort has recently been started.

Extensions of the second kind naturally fulfill the requirements for representing statistical information. Additionally, because of the much tighter integration on the formal level, they are also much more appropriate for Ontology matching and aligning and also for ontology learning by means of Bayesian machine learning methods. The same holds for ontology population or document classification, respectively. E.g. (Straccia & Troncy, 2006) have proposed methods for learning probabilistic mappings between OWL ontologies that are represented as very simple pDatalog rules. These methods have been implemented in the oMAP framework. The pDatalog rules that can be learned in the oMAP framework are contained in pOWLLite^{-} as well. Thus, those mappings are very much related to POWLLite^{-} and pOWLLite^{EQ}. Probabilistic disjunctive description logic programming as described above has also been proposed for usage in the area of the usage of ontology mappings and information integration. These considerations have been theoretical and no implementation has been provided, yet, but is considered as future work. In (Predoiu, 2006), Bayesian Description Logic Programs have been proposed solely for the representation of mappings and the uncertainty inherently associated with any automatically discovered mapping. An implementation, however, is not yet provided, but under development. The only further formalism for which a mapping scenario has been considered is BayesOWL. As each BayesOWL ontology corresponds to a Bayesian Network, in the mapping scenario, Bayesian Networks are mapped to each other. Hence, this scenario is computationally very expensive. The formalism which has been identified as being the most appropriate for information integration is probabilistic disjunctive description logic programming because of its expressivity concerning the ontologies to be mapped and the mappings and the possibility to deal with inconsistencies introduced by mappings to a certain extent which needs to be further investigated. For the other probabilistic extensions surveyed in this paper, no mapping scenario has been considered. Most of them have been proposed without the area of ontology mapping and information integration in mind and therefore they all have drawbacks concerning their usage in this area. Furthermore, no research on learning or using mappings has been performed yet in any of the formalisms except of pOWLLite^{-}.The probabilistic extensions that integrate Semantic Web languages or subsets thereof tightly with a probabilistic model, can be distinguished as follows:

- Extensions that consider not only the semantics but also the syntax of established Semantic Web languages, examples being pRDF and BayesOWL. Both support only a small subset of the languages they extend probabilistically. pRDF extends basically only the three RDF built-in predicates for specifying subclass relations, instance and role membership with probabilities. Furthermore, RDF built-in predicates around properties (the subproperty relation, the definition of the range and the domain of properties) are allowed to be used classically in deterministic triples. BayesOWL has an even more limited expressivity than pRDF because it does not even allow to express uncertainty of properties and instances.
- Extensions that consider subsets of the Description Logics underlying OWL, examples being P-SHOQ(D) and P-CLASSIC. P-CLASSIC has a rather limited expressivity as it combines the description logic CLASSIC that has been designed for efficiency of reasoning and suffers thus of a limited expressivity with the probabilistic model of Bayesian Networks. CLASSIC is a very small subset of SHOQ(D). For P-CLASSIC no reasoning tools have been devised. P-SHOQ(D) has the full expressivity of SHOQ(D) and is very near to OWL-DL which corresponds to SHOIN(D). The only difference is that inverse roles cannot be specified. However, for P-SHOQ(D) no reasoning tools exist either. Furthermore, the proposed reasoning algorithm can be expected to have a very high complexity because it involves solving a linear equation system.
- Extensions that consider integrations of a Logic Programming variant and a Description Logic underlying OWL. Such extensions are Bayesian Description Logic Programs, pOWLLite^{-} and pOWLLite^{EQ}, probabilistic Description Logic Programs and probabilistic Disjunctive Description Logic Programs. We think that probabilistic extensions of integration formalisms that integrate Description Logics and Logic Programs are very important also because Logic Programming is a very important paradigm especially present in the database area. Furthermore, as shown by the Rule-Interchange-Format working group at the W3C[6] that intends to carry over the Logic Programming paradigm into the Semantic Web, there is a huge interest in representing rules on the Web. In the next paragraph we will shortly summarize a comparison of the form of integration between DL and LP, the expressivity of the formalisms and the tightness of the combination between the deterministic logical model and the probabilistic model.

Two of the probabilistic approaches that integrate Logic Programming with Description Logics, integrate only a subset of OWL. These approaches are Bayesian Description Logic

Programs and pOWLLite^{-}/pOWLLite^{EQ}. Bayesian Description Logic Programs combine pure Description Logic Programs, i.e. Datalog without equality and negation, a common subset that is shared by the Description Logics underlying OWL and the Logic programming paradigm, with Bayesian Logic Programs. The integration of the deterministic and the probabilistic model is very tight and yields even a subset of the probabilistic model. pOWLLite^{-} and pOWLLite^{EQ} are intended to be a probabilistic extension of Description Logic Programs as well (the latter extends them also with equality). Besides a probabilistic extension of Description Logic Programs (possibly extended with equality) also probabilistic Horn rules are supported that increase the expressivity and it is unclear whether the expressivity ends up in full pDatalog. However, as negation is allowed and also equality, pOWLLite$^{-/EQ}$ seems to support a larger expressivity of the deterministic model. The probabilistic models used in Bayesian Description Logic Programs and pOWLLite$^{-/EQ}$ differ as well. Bayesian Logic Programs do not support negation and are a compact representation of a Bayesian Network. pDatalog supports negation under the well-founded semantics and until now no relation to Bayesian Networks has been found.

Differently from Bayesian Logic Programs and pOWLLite$^{-/EQ}$, probabilistic Description Logic Programs and probabilistic Disjunctive Description Logic Programs support full OWL-Lite and OWL-DL and integrate them with stratified logic programs, logic programs under the well-founded and under the answer set semantics. These approaches have a strong theoretical basis and all of them combine the deterministic model with independent choice logic as probabilistic model. The query language supports differently form Bayesian Logic Programs and pOWLLite^{-}/pOWLLite^{EQ} queries for probabilistic intervals. The query language is very expressive and reasoning is very complex because it involves solving a linear equation system like with P-SHOQ. However, for a restricted subset of probabilistic Disjunctive Description Logic programs, a polynomial complexity has been shown. This subset consists of a Description Logics knowledge base lying in a subset of the Description Logic programming fragment and of a Logic Program that corresponds to Datalog with negation that is locally stratified.

Most of the approaches that probabilistically integrate the Logic Programming paradigm with the Description Logics paradigm, provide own reasoners. For Bayesian Description Logic Programs, the reasoner Balios (Kerstin & Dick, 2004) that has been implemented for its probabilistic model which is a superset of itself can be used. For pOWLLite$^{-/EQ}$, HySpirit or Pire which are reasoners for full pDatalog which is their underlying probabilistic model can be used. In fact, an implementation for pOWLLite$^{-/EQ}$ basing on PIRE exists. For probabilistic Description Logic Programs and probabilistic Disjunctive Description Logic Programs no reasoners exist yet.

FUTURE RESEARCH DIRECTIONS

As overall conclusion, we can summarize that until recently, research has not paid much attention to uncertainty in the area of the Semantic Web. However, it gains more and more interest and new approaches considering uncertainty tend to emerge. Still, many of these approaches are rather half-baked and a lot of things are missing:

- **Reflections on gathering probabilities.** *Where do the probabilities used in the web come from? What kinds of probabilities exist?* Cali & Lukasiewicz (2007) make the first proposal to distinguish between mapping trust, mapping error or plain mapping probabilities. However, we think that this is just a very first step and might be a beginning for new insights into the types and usages of probability usage, depending on the event space and intended semantics.

How can those probabilities be gathered? (Straccia & Troncy, 2006) make proposals for learning very simple pDatalog rules. Investigations of methods for learning more complex structures of different probabilistic models would enable the Semantic Web community to anticipate in which forms a Semantic Web where automatic information integration would be possible.

- **Reflections on which probabilistic models are suitable for which subareas of the Semantic Web.** I.e. investigations of the applicability and usefulness of probabilistic extensions of Semantic Web languages in the different areas that need to consider uncertainty have to be done. E.g. it has to be seen whether a probabilistic Logic Programming approach is better suited for discovering and representing mappings than a purely probabilistic Description Logic one when only OWL ontologies and no rules are involved. This requirement is interweaved with the requirement above because the investigations on the different kinds of probabilities might lead to usefulness results. Furthermore, investigations on methods for learning those different probabilistic Semantic Web extensions, might naturally lead to further insights of the usability of the different formalisms in the different areas by means of complexity results and learnability results.
- **Reflections on cyclic probabilistic representations:** None of the above mentioned probabilistic extensions of Semantic Web languages can deal with cyclic representations. We deem this as a severe drawback because of the open and free nature of the Semantic Web. If ontologies, logic programs and mappings between them are considered as a whole, cyclic descriptions are very likely to occur and are not avoidable. Only in small toy worlds, cycles can be avoided. It has to be investigated in which ways cyclic probabilistic representations can be dealt with.
- **Reasoning methods and implementations:** Reasoning tools in general are not provided for the languages themselves, only for related logical formalisms which can used by means of wrappers but are not optimized for the languages at hand. If there are reasoning tools that are specialized for the languages themselves, then they support only a part of the language like in the case of pRDF. Research needs to focus on the development of optimized reasoning methods and reasoning tools need to be implemented in order to enable the usage of uncertain statements in the Semantic Web and in order to make reasoning feasible facing the huge amount of ontologies and data that can be expected to be present in the future of the Semantic Web. For example research on approximate and distributed reasoning would enable feasible query answering with large-scale knowledge bases and instance bases like imposed by the Semantic Web. None of the approaches above employ or consider currently any form of approximate or distributed reasoning.

ENDNOTES

1. For the sake of simplicity we are considering here only a part of the ontologies. The complete ontologies can be found at http://oaei.ontologymatching.org/.
2. Due to the semi-decidability of First-order logic this can only be true if the translation allows for networks of infinite size.
3. Note that Description Logic Programs are called OWL Lite$^-$ in (Nottelmann & Fuhr, 2005). This is the reason for calling its probabilistic extension pOWL Lite$^-$.
4. Note that although the formalism is called description logic programs like the formalism in (Grosof et al., 2003), it is a completely different language as it goes beyond the common subset of Description Logics and Logic Programming. In order to hint the difference, we are using lower case letters for this formalism while we call the formalism from Grosof et al. (2003) Description Logic Programs.

5 Note that conjunction in the head is allowed with probabilistic description logic programs with special DL-atoms as well, because rules with conjunction in the head can be split to regular horn rules by means of the Lloyd-Topor-Transformation (Lloyd & Topor, 1984).

Chapter 7.6
Estimating the Privacy Protection Capability of a Web Service Provider[1]

George O.M. Yee
Institute for Information Technology, National Research Council, Canada

ABSTRACT

The growth of the Internet has been accompanied by the growth of Web services (e.g., e-commerce, e-health, etc.), leading to important provisions put in place to protect the privacy of Web service users. However, it is also important to be able to estimate the privacy protection capability of a Web service provider. Such estimates would benefit both users and providers. Users would benefit from being able to choose (assuming that such estimates were made public) the service that has the greatest ability to protect their privacy (this would in turn encourage Web service providers to pay more attention to privacy). Web service providers would benefit by being able to adjust their provisions for protecting privacy until certain target capability levels of privacy protection are reached. This article presents an approach for estimating the privacy protection capability of a Web service provider and illustrates the approach with an example.

INTRODUCTION

This work considers Web services to be: a) Web-based services that employ Extensible Markup Language (XML), Web service Definition Language (WSDL), Simple Object Access Protocol (SOAP), and Universal Description, Discovery, and Integration (UDDI) in a Service-Oriented Architecture (SOA) (O'Neill, Hallam-Baker, MacCann, Shema, Simon, Watters, et al., 2003); and b) existing and previous generations of Web-based applications that involve Web browsers interacting with Web servers that do not employ XML, WSDL, SOAP, or UDDI. This work applies to all Web services described above.

Numerous Web services targeting consumers have accompanied the rapid growth of the

Internet. For example, Web services are available for banking, shopping, learning, healthcare, and government online. However, most of these services require a consumer's personal information in one form or another, leading to concerns over privacy. For Web services to be successful, privacy must be protected. Various approaches have been used to protect personal information, including data anonymization (Iyengar, 2002; Kobsa & Schreck, 2003) and pseudonym technology (Song, Korba, & Yee, 2006). Approaches for privacy protection that are in the research stage include: treating privacy protection as an access problem and then bringing the tools of access control to bear for privacy control (Adams & Barbieri, 2006); treating privacy protection as a privacy rights management problem using the techniques of digital rights management (Kenny & Korba, 2002); and considering privacy protection as a privacy policy compliance problem, verifying compliance with secure logs (Yee & Korba, 2004).

It is also important to estimate the privacy protection capability of a Web service provider. Suppose such estimates for similar Web services A, B, and C are made available to consumers. This leads to the following benefits. If the consumer has to choose one service from among A, B, and C, then the estimates can help the consumer decide which service to select (probably the service that has the highest capability for privacy protection). In addition, the fact that consumers have access to these estimates may encourage service providers to pay more attention to protecting consumer privacy and result in higher levels of consumer trust and acceptance of Web services. Alternatively, Web service providers can use such estimates to implement services that meet predefined goals of privacy protection. Predefined levels of the estimates could be expressed as quality-of-service requirements. The estimates could then be evaluated for incremental versions of a service until the predefined levels are achieved.

The objectives of this article are to a) define estimates of the privacy protection capability of a Web service provider, b) show how the estimates can be calculated, and c) illustrate the calculation of the estimates using a Web service example.

This article extends the work of Yee (2006) by: a) improving the practicality of the approach by refocusing on estimating privacy protection capability rather than measuring how well privacy is protected; b) updating the definition of the estimates; c) updating the method for calculating the estimates; d) updating and extending the application example; e) enlarging the related works section; f) adding an evaluation section; and g) improving the clarity of the writing in all sections.

The rest of this article is organized as follows. Section "Estimates of Privacy Protection Capability" introduces the privacy protection model and defines the estimates. "Calculation of the Estimates" shows how to calculate the estimates. The section called "Application Example" illustrates the calculation of the estimates. A discussion of related work then follows. "Evaluation of Approach" discusses the strengths and weaknesses of the approach. Finally, the article ends with conclusions and directions for future research.

ESTIMATES OF PRIVACY PROTECTION CAPABILITY

Privacy

In order to define estimates of a Web service provider's capability to protect consumer privacy, it is necessary first to examine the nature of personal privacy. As defined by Goldberg, Wagner, and Brewer (1997), privacy refers to the ability of individuals to *control* the collection, retention, and distribution of information about themselves. This leads to the following definitions for this work.

DEFINITION 1: *Privacy refers to the ability of individuals to control the collection, use,* *retention, and distribution of information about themselves.*

DEFINITION 2: *A provider's protection of user privacy refers to the provider's use of provisions to give a user desired control over the provider's collection, retention, and distribution of information about the user.*

Definition 1 is the same as given by Goldberg et al. (1997) except that it also includes "use." To see that "use" is needed, consider, for example, that one may agree to give out one's credit card number (private information) to pay for one's own purchase but not to pay for someone else's purchase. The "provisions" in Definition 2 refer to whatever means or technologies are needed to give the user the required control (uphold the user's privacy); for example, access control mechanisms, policy negotiation mechanisms, and policy compliance mechanisms. These provisions depend on the nature of the control required by the user. For example, if the user specifies that the user's information is not to be kept past a certain date, the provider must have in place a provision to track how long the information has been in its possession.

It follows from Definition 2 that if the service provider is to make provisions to protect the user's privacy, it needs to know how the user wishes to control personal information. Thus, there must be a means of communicating the nature of this control, from the user to the service provider. This communication is normally carried out using a statement of privacy preferences called a *privacy policy*. Figure 1 is an example of a user privacy policy for e-learning from Yee and Korba (2005). In Figure 1, each item of information about the user corresponds to a "privacy rule" that spells out who can collect the information, how the item is to be used (purpose), how long it can be retained, and who it can be disclosed to. For example, the information item "name, address, tel" is to be used for identification; it may be collected by E-Learning Inc., it can be retained by E-Learning Inc. indefinitely, and E-Learning Inc. must not disclose it to any other party. Figure 2 illustrates the use of a privacy policy to express how the user wishes to control private information. The arrows from the user are numbered to show that the privacy policy must come first. The bidirectional arrow between the user and the privacy policy indicates that the user both specifies the policy and complies with it. On the provider side, the provisions for user control (blue box) must comply with the privacy rules in the user's privacy policy, giving the user desired control over the user's personal information. The service provider would have to agree to comply with the user's privacy policy before it can receive any of the user's private information. Where the service provider does not agree to the user's policy, the user can negotiate with the provider (Yee & Korba, 2003a, 2003b) until there is agreement, or the user can try a different provider.

Privacy Policy Violations

Once the provider has agreed to comply with the user's privacy policy and is in possession of

Figure 1. Example privacy policy for e-learning

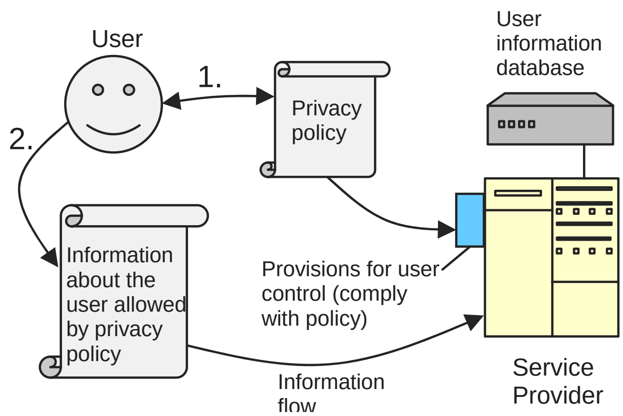
Figure 2. Using a privacy policy to express user control over private information



the user's private data, the user's privacy is fully protected, provided there are no violations of the user's privacy policy. To define estimates of a provider's capability to protect privacy or to avoid privacy policy violations, it is necessary to look at where violations can occur. To see where violations can occur, the flow of the private information is traced, from the point where it leaves the service user to where the information is used and stored. This leads to the next definition.

DEFINITION 3: *The private information path (PIP) is the path drawn through all points traversed by the private information, from the point where it leaves the service user to the point(s) where it is stored, possibly traversing points in between where it is used. The PIP can traverse multiple providers where providers disclose the user's private information to other providers.*

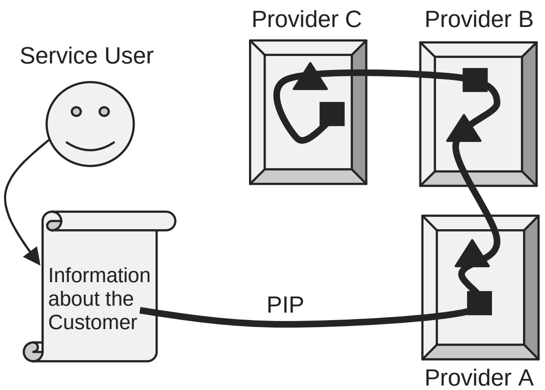
The PIP (see Figure 3) is an informal mechanism to help the security/privacy analyst visualize where attacks on the private information can happen.

Privacy violations can be classified as internal and external violations, as follows:

DEFINITION 4: *An internal violation (IV) (or inside attack) of privacy policy is one that is carried out by an insider of the provider organization (i.e., someone who has special data access privileges by virtue of an association with the organization [e.g., employee]), whose access and use of the private information does not comply with the user's privacy policy. An external violation (EV) (or outside attack) of privacy policy is one that is carried out by a noninsider of the provider organization, whose access and use of the private information does not comply with the user's privacy policy.*

An example of an internal violation is where an employee secretly copies private information and sells it to the provider's competitors, in violation of privacy policy. Other examples of internal violations are from the category of unintentional or accidental violations, where the user's private information could be leaked (e.g., private data inadvertently sent in an e-mail) or misplaced (e.g., recently, a prominent bank was discovered to be faxing confidential customer records to a farmer) due to poor business processes. Thus, an internal violation may be very difficult to detect since on the surface the employees may appear to comply with the user's privacy policy. An example of an external violation is where an attacker unknown to the provider plants a Trojan horse inside the

Figure 3. Example PIP; squares indicate storage points, triangles indicate use points



provider's computer system to steal confidential private data.

Estimating a service provider's capability to protect privacy involves looking at what provisions are in place to prevent IV and EV, that is, prevent attacks that violate the user's privacy policy.

Provisions against IV would have to cover both violations due to poor information management (e.g., lack of suitable tracking mechanisms) and violations that are intentional and malicious. These violations correspond to information management vulnerabilities within the provider organization that allow the violations to occur. Examples of such vulnerabilities are:

- Lack of anyone in the provider organization who is accountable for the private information in the organization's possession.
- Poor business processes that lack mechanisms to track which data are used where or used for what purpose; for example, employees casually providing the names of clients for a survey.
- Poor education and enforcement of company policies regarding the proper care and handling of personal information; for example, employees bringing work home that contains private information in the clear.
- Divulging personal information unwittingly to an attacker who uses social engineering.
- Lack of adequate security provisions to protect private information; for example, private data stored in the clear in data bases.
- Poor working conditions that give rise to employees feeling unfairly treated by management (can lead to employees seeking revenge through IV).

The following provisions aim to prevent IV or lessen the probability of it occurring:

- Educating employees and effectively enforcing company policies regarding the proper care and handling of personal information.
- Training employees on how to recognize and resist social engineering that targets the divulgence of personal information.
- Use of a privacy policy compliance system (PPCS) (Yee & Korba, 2004; Lategan & Olivier, n.d.) that automatically ensures that the user's privacy policy is not violated.
- Use of a monitoring system to monitor how insiders make use of the private data; the monitoring can be done in real time or offline (users' sessions recorded).
- Use of cryptographically secure logs (these logs can be later inspected to check for policy violations) to record each transaction involving private data on all servers.
- Use of reputation mechanisms to record and indicate the past performance of the provider organization in terms of integrity (e.g., Better Business Bureau).
- Use of seals of approval that attest to the fact that the provider organization has undergone and passed rigorous inspections of its processes; for example, ISO 9001: 2000 (International Organization for Standardization, n.d.).

This list is of course not exhaustive. A provider may employ none, one, or more than one of these provisions.

In the case of provisions against EV, the question to ask is: "What are possible EV violations of a privacy policy?" These violations are carried out by attackers who have not been granted access to the targeted private information. These attackers target a range of security vulnerabilities, from software systems that can be breached to access the private information to simple theft of laptops and other devices used to store private information.

Our estimates of the capability to protect privacy will depend on the provisions that have been put in place against both IV and EV vulnerabilities.

There are situations in which multiple service providers may be involved in a single service. In these situations, a provider may share private information with other providers. For example, an online book store (e.g., Amazon.com) may make use of an online payment service (e.g., Paypal.com) and a shipping service (e.g., fedex.com) in order to sell the consumer a book. For the sake of exposition, the *first* provider is the one with which the user chooses to interact. *Second* providers are providers with which the first provider shares the user's private data in order to complete its purpose (such as selling a book in the example above). *Third* providers are ones with which the second provider shares the original user's private data in order to use the third providers' services. Similarly, it is possible to define *fourth* providers, *fifth* providers, and so on. For convenience, label second, third, fourth, and so forth providers as *chained* providers. In order to evaluate the first provider for its capability to protect privacy, it is necessary to carry out the same evaluation for all chained providers that are linked to the first provider in terms of service usage, as just described, and that receive the original user's private information due to this linkage. In other words, IV and EV would need to be examined not just for the first provider but also for each chained provider in turn. Second providers would be identified in the original user's privacy policy under "Disclose-To" (see Figure 1). Similarly, third providers would be identified in the first provider's privacy policy, fourth providers would be identified in the second provider's privacy policy, and so on. Of course, all second providers have to agree to comply with the first provider's privacy policy (the first provider is the "user" here), all third providers have to agree to comply with the second provider's privacy policy, and so on. Further, the first provider would incorporate into its privacy policy the portions of the original user's privacy policy that relate to the private information to be shared with the second providers, each second provider would incorporate into its privacy policy the portions of the original user's privacy policy that relate to the private information to be shared with the third providers, and so on.

Past Violations

Intuitively, a service provider's record of past privacy violations should impact its future capability of privacy protection. As for a sex offender, one could say that the fact that a service provider has violated privacy in the past means that it is more likely to lack the capability of privacy protection in the future. However, the comparison may not be so clear cut. A service provider may be intensely motivated by profit and public image. In fact, one could argue that a company that has violated privacy in the past is more likely to put measures in place to avoid violating privacy in the future in order to protect its public image and profit, especially if knowledge of the past violation is in the public domain. In this case, the capability of privacy protection in the future is *increased* if it has violated privacy in the past, not decreased. The influence of a provider's past privacy violations on its future capability of protecting privacy can be postulated as depending on at least the following factors:

- The type of service provider, for example, profit-oriented, nonprofit-oriented: A profit-oriented provider will probably want to put measures in place to avoid future privacy violations to protect its profit, increasing its future capability of protecting privacy;
- The severity of the past privacy violation: The type of information violated and the number of people affected by the violation contribute to this severity, for example, a disclosure of credit card numbers affecting 10,000 people would generally be regarded as more severe than a disclosure of personal e-mail addresses affecting 100 people; probably the more severe the violation, the more the service provider is motivated to avoid violations in the future, likely increasing its future capability of protecting privacy;
- The time when new measures against future violations were installed: If the installation occurred after the past violations, this could indicate that the service provider was serious about avoiding future violations, likely increasing its future capability of protecting privacy. Of course, the installation may have been carried out for other reasons (e.g., window dressing to prop up the company's shares); it is difficult to be sure, but in general perhaps the provider can be given the benefit of the doubt.

Given the above discussion, it is suggested that past violation information not be integrated into estimates of future capability of protecting privacy, but rather that it is treated simply as *contextual information*, to be considered in conjunction with the estimates developed below as "support," that is, suggesting an increase in future privacy protection capability. This is primarily due to the imprecise nature of any conclusions that might be drawn from past violations, as discussed. Table 1 shows how the above factors from past violations can, to varying degrees, support the future capability of protecting privacy. To use Table 1, one would first calculate the estimates of future privacy protection capability as presented below. Then these estimates would be supported by the entry in Table 1 that corresponds to the choice of past violation influencing factors down the left side and across the top of the table. If the service provider has no past privacy violations, Table 1 does not apply, and the estimates are not affected by past violations.

Note that the above ideas on provider behavior in response to a privacy violation have not been verified. This is left for future work.

Definition of the Estimates

An estimate of a service provider's capability for protecting the service user's privacy may be defined as follows:

Table 1. Support for future privacy protection capability based on the service provider's response to past violations

	Nonprofit-Oriented Service Provider		Profit-Oriented Service provider	
Severity of Past Violations	No New Measures Installed Post Violations	Some New Measures Installed Post Violations	No New Measures Installed Post Violations	Some New Measures Installed Post Violations
Low	Very Low Support	Low Support	Low Support	Medium Support
Medium	Very Low – Low Support	Low-Medium Support	Low-Medium Support	Medium-High Support
High	Low Support	Medium Support	Medium Support	High Support

- **DEFINITION 5:** An *estimate* of a provider's capability for protecting user privacy is a numerical rating (e.g., percentage) that indicates the approximate degree to which the provider is capable of avoiding IV and EV.

In Definition 5, suppose for example that the estimate (rating) of a provider's capability for protecting user privacy is 70%. This means that the provider's installed provisions are *capable* of avoiding violations of user privacy approximately every 7 out of 10 times. This does NOT mean that the provider's installed provisions *actually* avoid the violations approximately every 7 out of 10 times. An estimate as described in Definition 5 only rates capability; rating actual privacy protection performance would be much more complex and is not needed to achieve the benefits claimed for the approach proposed here.

In Definition 5, the capability to avoid IV and EV depends on effective protective provisions (e.g., encrypting the private data, together with careful encryption key management) that the organization has in place to prevent violations. Let E denote an estimate of capability to protect privacy. By Definition 5, E will need to account for the provisions used against IV and EV.

To account for the provisions against IV, we propose that a special privacy impact assessment (PIA) (Treasury Board of Canada, n.d.), explained below—extended to identify vulnerabilities that can lead to malicious IV—be carried out to identify IV vulnerabilities. Suppose that such an assessment identified that m IV vulnerabilities and countermeasures (provisions against IV) are in place for p of these vulnerabilities. To account for provisions against EV, we propose that a special security threat analysis (Salter, Saydjari, Schneier, & Wallner, 1998), explained below, oriented towards discovering EV vulnerabilities be carried out. Suppose that this analysis identified that n security vulnerabilities and countermeasures (provisions against EV) are in place for q of these vulnerabilities. Then, one formulation of E is (See Box 1).

Another formulation of E is:

$E_2 = (e_i, e_e)$

where e_i accounts for the provisions used against IV and e_e accounts for the provisions used against EV, and (See Box 2).

E_1 has the advantage of providing a single number for ease of comparison between different providers. A threshold t for E_1 may be predetermined such that for E_1 above t, the provisions

Box 1.

$$E_1 = (p + q) / (m + n), \quad \text{if } m + n > 0, \quad \text{so that } 0 \le E \le 1$$
$$= 1, \quad \text{if } m + n = 0.$$

Box 2.

$$e_i = p/m, \quad \text{if } m > 0, \quad \text{so that } 0 \le e_i \le 1$$
$$= 1, \quad \text{if } m = 0$$

$$e_e = q/n, \quad \text{if } n > 0, \quad \text{so that } 0 \le e_e \le 1$$
$$= 1, \quad \text{if } n = 0.$$

installed by the provider against IV and EV are deemed to give it an adequate capability to protect privacy.

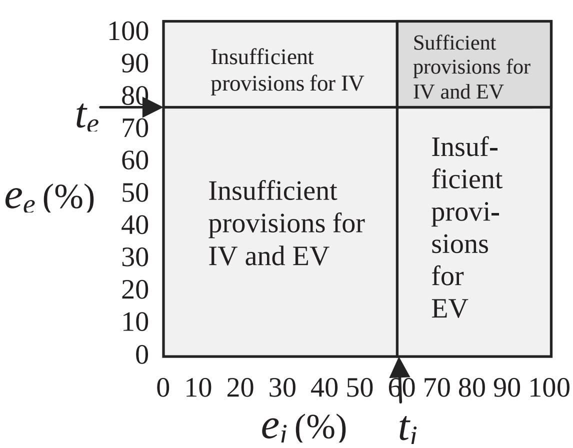
E_2 has the advantage of focusing in on where an organization stands in terms of its provisions against IV or EV separately. Thresholds t_i and t_e may be predetermined for e_i and e_e respectively, such that for e_i or e_e above its respective threshold, the corresponding installed provisions against IV or EV are deemed to give the provider an adequate capability to protect against IV or EV. In practice, e_i and e_e may be expressed as percentages that define a region in a 100 x 100 plane in which a provider's capability to avoid privacy policy violations is adequate (acceptable) (shaded region in Figure 4).

We will use both E_1 and E_2. The thresholds t, t_i, and t_e may be set by a privacy authority, such as a privacy commissioner, responsible for ensuring that the public's privacy is protected.

For chained provider situations (see above), the evaluation of E requires special treatment. The following rule is proposed for these situations.

- CHAINED RULE: *E evaluation for a service with chained providers:* A first provider passes E evaluation (i.e., each estimate is above or equal to its threshold) if and only if the first provider and each of its chained providers that receives the original user's private information all pass E evaluation.

Figure 4. Region (shaded) in which a service provider's capability to protect privacy is acceptable



The chained rule ensures that if at least one chained provider that receives the original user's private data fails E evaluation, the corresponding first provider is also regarded as having failed, even if it itself passes. This outcome seems to agree with personal wishes since the original user would not want private information abused by a chained provider after the user placed trust in the first provider.

CALCULATION OF THE ESTIMATES

Determination of *m* and *p* for IV

This determination requires a special PIA (Treasury Board of Canada, n.d.) in order to identify IV vulnerabilities and provisions against these vulnerabilities. A basic description of how a PIA is carried out, along with an extension to identify vulnerabilities that could lead to malicious IV follows.

A PIA is a comprehensive process designed to assist organizations to determine the impacts of program and service delivery initiatives on individual privacy. It has the following main stages:

a. Project Initiation: Define the scope for the PIA, allocate team resources, and adapt PIA tools according to the scope. The team may consist of privacy and security experts, legal experts, program managers, system managers, and so on.
b. Data Analysis: Describe proposed business process diagrams and identify clusters of personal information in business processes. Develop detailed data flow charts

c. Privacy Analysis: Complete privacy analysis questionnaires. Discuss answers to questions that require further detail. Identify and describe privacy issues and implications
d. Privacy Impact Assessment Report: Summarize the privacy risks and evaluate the degree of risk involved. Identify and discuss actions or options to mitigate the risks. End by taking any other considerations into account and describe the path forward.

We are primarily interested in the vulnerabilities identified by the privacy analysis portion of the PIA through a series of questionnaires. The latter are concerned with the management of private information in order to comply with privacy legislation. To identify vulnerabilities that could lead to malicious IV, we propose extending the privacy analysis with an additional questionnaire designed to discover risks that could result in malicious IV, as shown in Table 2, to be used in conjunction with the PIP.

In identifying vulnerabilities, the PIA team may weigh the vulnerabilities in terms of how likely they are to lead to violations, and eliminate the ones that are unlikely to be violated. The weighing process may consider such factors as risk to the violator that the violator could be caught as well as the violator's motivation for the violation.

The total number *m* of IV vulnerabilities is the sum of the number of vulnerabilities identified using this questionnaire and the number of vulnerabilities identified in the above PIA that are potential internal violations. The number of provisions already in place countering these vulnerabilities gives *p*. Since an organization may plan to install a certain number of such provisions

Table 2. Questionnaire to identify vulnerabilities leading to malicious IV

	Question	Rationale
1.	Is the private information of high value to outside agencies or a competitor?	The higher the value, the more a malicious attacker will be tempted to steal and sell the information.
2.	What are some possible ways for an unauthorized insider to gain access to the private information?	This question will identify security weaknesses.
3.	What are some possible ways for an authorized insider to violate the privacy policy?	This question will identify nonsecurity weaknesses (e.g., using the private information for a different purpose).
4.	Does the organization have an employee assistance program that includes counseling and help with financial difficulties?	Such a program may eliminate some financial motivation for a malicious IV.
5.	Does the organization have an ombudsman or other impartial agent to assist employees with their grievances?	Such an impartial agent may eliminate or reduce the motivation to seek revenge by committing a malicious IV.
6.	Does the organization have a history of perceived injustices to employees?	If the answer is "yes," employees may be motivated by revenge to commit a malicious IV.
7.	Does the organization conduct a stringent background and reliability check on a candidate for employment prior to hiring the candidate?	While a background and reliability check is not guaranteed to weed out potential inside attackers, it should eliminate those with criminal backgrounds.
8.	Does the organization require candidates for employment to disclose any potential conflicts of interest they may have with respect to their new employment and any outside interests prior to hire? Does the organization require ongoing disclosure of conflicts of interest after hire?	Eliminating conflicts of interest should reduce related motivations for malicious inside attacks. For example, an inside attacker may secretly compromise private information in favor of an outside interest, believing that the compromise is undetected.

in the future, it is possible to obtain *p*, reflecting both provisions in place and planned. However, the author's opinion is that *p* should count only provisions already in place, since something that is planned may never actually happen.

Determination of *n* and *q* for EV

This determination requires a threat analysis of security vulnerabilities in the organization's systems that could allow EV to happen. An overview of threat analysis follows.

Threat analysis or threat modeling is a method for systematically assessing and documenting the security risks associated with a system (Salter et al., 1998). The results can help development teams identify the strengths and weaknesses of the system and serve as a basis for investigations into vulnerabilities and required mitigation. Threat modeling involves understanding the adversary's goals in attacking the system based on the system's assets of interest. It is predicated on that fact that an adversary cannot attack a system without a way of supplying it with data or otherwise accessing it. In addition, an adversary will only attack a system if it has some assets of interest. The following threat modeling terminology is selected from Salter et al. (1998):

- *Attack path*: A sequence of conditions in a threat tree that must be met for an attack goal (threat) to be achieved. A valid attack path (one with no mitigated conditions) is a vulnerability.
- *Threat*: The adversary's goals, or what an adversary might try to do to a system. Threats to a system always exist, regardless of mitigation.
- *Threat Tree or Attack Tree*: An analysis tool that describes the attack paths for a particular threat. A threat tree is comprised of hierarchical conditions and allows the threat to be characterized. The root of the threat tree is the threat to which the tree corresponds.

The method of threat analysis given by Salter et al. (1998) was intended for external threats to systems. The steps in this method are:

1. Create attack trees for the system.
2. Apply weights to the leaves.
3. Prune the tree so that only exploitable leaves remain.
4. Generate corresponding countermeasures.
5. Optimize countermeasure options.

However, the above steps are oriented towards the development and implementation of systems. In this work, it is not necessary to optimize the countermeasures since we are not concerned with implementation. On the other hand, it is necessary to identify the threats before creating the attack trees. Thus, the above steps are modified to:

1. Identify threats on the user's private data.
2. Create attack trees for the provider's service.
3. Apply weights to the leaves.
4. Prune the tree so that only exploitable leaves remain. Count the number of such leaves or vulnerabilities (this gives the *n*).
5. Determine if countermeasures are in place for the vulnerabilities found in Step 4. Count the number of these vulnerabilities so mitigated (this gives the *q*).

A description of each step follows.

Step 1: Identify threats on the user's private data. This step requires experience and imagination and may involve confirming details with management or the developers of the service.

Examine the architecture and all available details of the service and enumerate possible outside threats on the user's private data. Represent the system pictorially to get the big picture. It is useful to identify the main or root threat which includes most if not all other threats, for then only one attack tree needs to be created. Disregard any existing provisions against outside threats; they will be accounted for in Step 5. For example, a possible outside threat for an online banking service is theft of private information from the bank's customer information database.

Step 2: Create attack trees for the provider's service. Corresponding to each treat identified in Step 1, systematically create an attack tree by putting yourself in the adversary's place in finding the weak points in the work processes or the service system and the paths which will lead to realizing the threat. This analysis terminates in a series of vulnerability leaves for each attack tree. (In this work, each attack tree is represented by hierarchical indented headings rather than pictorially, which can take up too much space and become unwieldy).
