Contents

Volume I

Section I. Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of Web technologies. Chapters found within these pages provide an excellent framework in which to position Web technologies within the field of information science and technology. Individual contributions provide overviews of the mobile Web, semantic Web, and Web 2.0, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of Web technologies.

Section II. Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of Web technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful Web sites, Web-based applications, and Web portals are provided.

Volume II

Section III. Tools and Technologies

This section presents extensive coverage of the technology that informs and impacts Web technologies. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support the emergence and advancement of Web technologies. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Section IV. Utilization and Application

This section introduces and discusses the utilization and application of Web technologies. These particular selections highlight, among other topics, the application of semantic Web technologies to e-tourism, e-banking, and in car repairs as well as the adoption of Web services in digital libraries. Contributions included in this section provide excellent coverage of today's online environment and insight into how Web technologies impact the fabric of our present-day global village.

Section V. Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of Web technologies around the world. Chapters included in this section analyze social marketing, e-government, Web vendors, and Web tourism. The inquiries and methods presented in this section offer insight into the implications of Web technologies at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Volume III

Section VI. Managerial Impact

This section presents contemporary coverage of the managerial implications of Web technologies. Particular contributions address Web software engineering and Web-enabled employee life-cycle process management. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how Web technologies can inform their practices and behavior.

Section VII. Critical Issues

This section addresses conceptual and theoretical issues related to the field of Web technologies, which include issues related to usage, as well as failures and successes in Web implementation. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters address privacy concerns in Web logging, Web information extraction, and Web rules. Overall, contributions within this section ask unique, often theoretical questions related to the study of Web technologies and, more often than not, conclude that solutions are both numerous and contradictory.

Volume IV

Section VIII. Emerging Trends

This section highlights research potential within the field of Web technologies while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight emerging semantic Web applications, Web personalization, and learning on the Web. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Preface

Since its development just two decades ago, the World Wide Web has grown to become the infrastructure that supports innumerable applications essential to everyday life. It's not an exaggeration to claim that if you can think it, you can create a Web page about it. We use Web sites and the information they contain to create and connect with a seemingly unlimited amount of information. As such, it is important to understand the tools and technologies that support the continued growth of the Web and contribute to its role as an increasingly-pervasive aspect of our lives.

With the constant changes in the landscape of Web technologies, it is a challenge for researchers and experts to take in the volume of innovative advances and up-to-the-moment research in this diverse field. Information Science Reference is pleased to offer a four-volume reference collection on this rapidly growing discipline, in order to empower students, researchers, academicians, and practitioners with a wide-ranging understanding of the most critical areas within this field of study. This collection provides the most comprehensive, in-depth, and recent coverage of all issues related to the development of cutting-edge Web technologies, as well as a single reference source on all conceptual, methodological, technical and managerial issues, and the opportunities, future challenges and emerging trends related to the development, application, and implications of Web technologies.

This collection entitled, **"Web Technologies: Concepts, Methodologies, Tools, and Applications"** is organized in eight (8) distinct sections, providing the most wide-ranging coverage of topics such as: 1) Fundamental Concepts and Theories; 2) Development and Design Methodologies; 3) Tools and Technologies; 4) Utilization and Application; 5) Organizational and Social Implications; 6) Managerial Impact; 7) Critical Issues; and 8) Emerging Trends. The following provides a summary of what is covered in each section of this multi-volume reference collection:

Section 1, ***Fundamental Concepts and Theories***, serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Web technologies. Chapters such as "Tips for Tracking Web Information Seeking Behavior" by Brian Detlor, Maureen Hupfer, and Umar Ruhi and "A Proposed Template for the Evaluation of Web Design Strategies" by Dimitrios Xanthidis, David Nicholas, and Paris Argyrides provide analyses of user behavior and Web design. "Mobile Social Web; Opportunities and Drawbacks," by Thorsten Caus, Stefan Christmann, and Svenja Hagenhoff presents an overview of recent trends in mobile Web usage, which is becoming an increasingly important area of study as more and more people obtain Internet access for their wireless devices. Later selections, such as "Web 2.0 and E-Discovery" by Bryan Kimes and "The Power and Promise of Web 2.0 Tools" by G. Andrew Page and Radwan Ali explore the application of Web 2.0 as well as the issues companies must address as a result. These and several other foundational chapters provide a wealth of expert research on the elemental concepts and ideas which surround Web design and access.

Section 2, ***Development and Design Methodologies***, presents in-depth coverage of the conceptual design and architecture of Web sites, services, and systems. "Paralingual Web Design and Trust in E-

Government," by Roy H. Segovia, Murray E. Jennex, and James Beatty and "Designing Medical Research Web Sites" by Jonathan Grady, Michael B. Spring, and Armando J. Rotondi discuss context-specific Web design projects, highlighting the importance of recognizing the specific needs and requirements of different development initiatives. The latter half of this section introduces concepts that relate to the development of Semantic Web services. Chapters such as "A Semantic Web-Based Approach for Building Personalized News Services" by Flavius Frasincar, Jethro Borsje, and Leonard Levering and "Building Semantic Web Portals with a Model-Driven Design Approach" by Marco Brambilla and Federico M. Facca offer specific considerations for the creation of Semantic Web services, while later selections such as "Rule Markup Languages and Semantic Web Rule Languages" by Adrian Paschke and Harold Boley and "Semantic Web Rule Languages for Geospatial Ontologies" by Philip D. Smart, Alia I. Abdelmoty, Baher A. El-Geresy, and Christopher B. Jones present more technical considerations relating to the use and communication of rule languages in the Semantic Web. With 20 contributions from leading international researchers, this section offers copious developmental approaches and methodologies for Web services and technologies.

Section 3, ***Tools and Technologies***, presents extensive coverage of the various tools and technologies used in the development and implementation of Web services and applications. This comprehensive section opens with the chapters "New Paradigms: A Collaborative Web Based Research Tool," by Hamish Holewa, and "Adaptability and Adaptivity in The Generation of Web Applications," by Raoudha Ben Djemaa, Ikram Amous, and Abdelmajid Ben Hamadou, which describe new tools that support the development of Web applications and the challenges faced in the management and creation of new technology. "Migrating Web Services in Mobile and Wireless Environments," by Myung-Woo Park, Yeon-Seok Kim, and Kyong-Ho Lee revisits Web use on wireless devices, specifically exploring the mitigation and replication of Web services among mobile devices. Later selections such as "Web 2.0 Technologies: Social Software Applied to Higher Education and Adult Learning" by Teresa Torres-Coronas, M. Arántzazu Vidal-Blasco, Ricard Monclús-Guitart, M. José Simón-Olmos, and Araceli Rodríguez-Merayo and "Interactive Whiteboards in the Web 2.0 Classroom" by David Miller and Derek Glover provide insight into the use of specific Web tools (namely social software and interactive whiteboards) in educational settings. In all, this section provides coverage of a variety of Web tools and technologies under development and in use.

Section 4, ***Utilization and Application***, describes the implementation and use of an assortment of Web technologies. Including chapters such as "Semantic Web Take-Off in a European Industry Perspective" by Alain Léger, Jean Charlet, Johannes Heinecke, Paola Hobson, Lyndon J.B. Nixon, François Goasdoué, and Pavel Shvaiko and "Semantic Web for Media Convergence: A Newspaper Case" by Ferran Perdrix, Juan Manuel Gimeno, Rosa Gil, Marta Oliva, and Roberto García provide specific insight into the application of Web tools and technologies in both the professional and private sector. "Mailing Lists and Social Semantic Web" by Sergio Fernández, Jose E. Labra, Diego Berrueta, Patricia Ordóñez de Pablos, and Lian Shi describes the use of mailing lists and presents a method for extracting data from these lists. Later selections, such as "A Context-Based Approach to Web 2.0 and Language Education" by Gary Motteram and Susan Brown and "Exploring the Effects of Web-Enabled Self-Regulated Learning and Online Class Frequency on Students' Computing Skills in Blended Learning Courses" by Pei-Di Shen and Chia-Wen Tsai suggest approaches and consider the impact of Web-based learning on student performance. Contributions found in this section provide comprehensive coverage of the practicality and current use of Web technologies.

Section 5, ***Organizational and Social Implications***, includes chapters discussing the impact of Web technology on social and organizational practices. Chapters such as "Building Trust in E-Commerce through Web Interface," by Muneesh Kumar and Mamta Sareen and and "Swift Trust in Web Vendors:

The Role of Appearance and Functionality," by Xin Li, Guang Rong, and Jason B. Thatcher discuss the growth and influence of e-commerce and the important role trust plays in impacting e-marketplaces. Specific Web implementation and resulting implications of such initiatives are explored in selections such as "Assessing the Performance of Airline Web Sites: The ARTFLY Case" by Elad Harison and Albert Boonstra and "Aviation-Related Expertise and Usability: Implications for the Design of an FAA E-Government Web Site" by Ferne Friedman-Berg, Kenneth Allendoerfer, and Shantanu Pai. This section continues with discussions of Web accessibility and customization, concluding with a discussion of educational implications of Web technology. Overall, these chapters present a detailed investigation of how Web technology is implemented and how this implementation impacts the individual and society as a whole.

Section 6, ***Managerial Impact***, presents focused coverage of Web services and technology as it relates to improvements and considerations in the workplace. "Employee Life-Cycle Process Management Improvement with Web-Enabled Workflow Systems" by Leon Welicki, Javier Piqueres Juan, Fernando Llorente Martin, and Victor de Vega Hernandez presents a real-world case of constructing a Web-enabled worklflow for managing employee-life cycle processes, which include hiring and dismissing of employees. "Web Engineering in Small Jordanian Web Development Firms: An XP Based Process Model" by Haroon Altarawneh and Asim El-Shiekh describes a model for small Web project development and explains, from a managerial perspective, how this differs from the more large-scale implementation projects adopted by larger firms. In all, the chapters in this section offer specific perspectives on how work and Web technologies interact and inform each other to create more meaningful user experiences.

Section 7, ***Critical Issues***, addresses vital issues related to Web technology, which include privacy and quality, among other topics. Chapters such as "Privacy Concerns for Web Logging Data" by Kirstie Hawkey explore the issues that must be considered when collecting user data and offer recommendations for enhancing privacy. Later selections, such as "Search Engine-Based Web Information Extraction" by Gijs Geleijnse and Jan Korst, continue the discussion of information gathering and extraction which, in this chapter, is discussed in terms of approaches to expressing and sharing structured information in Semantic Web languages. This section continues by asking unique questions about information literacy, as well as presenting new solutions to questions about the social Web and Web services profiling.

The concluding section of this authoritative reference tool, ***Emerging Trends***, highlights areas for future research within the field of Web technology, while exploring new avenues for the advancement of the discipline. Beginning this section is "The Social Semantic Desktop: A New Paradigm Towards Deploying the Semantic Web on the Desktop" by Ansgar Bernardi, Mehdi Jazayeri, Stefan Decker, Cédric Mesnage, Ludger van Elst, Knud Möller, Gunnar Aastrand Grimnes, Michael Sintek, Tudor Groza, Leo Sauermann, and Siegfried Handschuh. This selection presents the Social Semantic Desktop project, addressing design considerations of a project whose aim is to blur the lines between individual applications and users' physical workspace. Trends in marketing are explored in "Social Media Marketing; Web X.0 of Opportunities" by Lemi Baruh with the aim of introducing new techniques for advertisers whose aim is to reach consumers through social media. These and several other emerging trends and suggestions for future research can be found within the final section of this exhaustive multi-volume set.

Although the primary organization of the contents in this multi-volume work is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore to ensure that the scholar, researcher and educator have access to the entire contents of this multi volume set as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. This aggregated database provides far more contents than what can be included in the print version in addition to continual updates. This unlimited access, coupled with the continuous updates to the database ensures that the most current research is accessible to knowledge seekers.

The diverse and comprehensive coverage of Web technologies presented in this four-volume authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamental concepts and technologies while fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of all aspects of Web technology.

Web Technologies:
Concepts, Applications, Trends and Research Issues

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

Web-based systems and technologies are now used for a vast number of applications, and this chapter aims to provide an overview of the technologies themselves and also the uses to which the Web is now put, as well as the social and political impact of this use. A number of important concepts underlie the Web as well as a good deal of jargon, and some of the main concepts and terms are explained here. Design and development of web-based systems is an important topic and this is briefly discussed along with some of the tools and issues involved in this development. It is impossible to do justice to the huge range of applications of the Web in an incredibly diverse range of areas, but this chapter attempts to do just this by examining some of the most important applications. Not all aspects of the Web can be considered to be either worthwhile or healthy for society as a whole and issues like identify theft and the distribution of pornography, both of which have been made easier by access to the Web, are also discussed. No technological innovation can be useful, however, until it has been adopted and the factors leading to adoption of some Web-based systems and not others, and to adoption of some aspects of these systems by one organisation and other aspects by another organisation are also discussed. Finally this chapter also tackles the issue of researching the Web; what this involves and what sort of methodologies might be appropriate in this socio-technical area.

THE WEB: TECHNOLOGY, APPLICATIONS AND PEOPLE

Today everyone knows of the World Wide Web and very many people around the world make daily use of its facilities. It is hard to imagine what it must have been like before the Web became such an important part of our lives, but it was only in 1989 that Tim Berners-Lee, based at the European Laboratory for Particle Physics (CERN[1]), in looking for a solution to the management and sharing of the large amounts of scientific information his colleagues created, wrote a proposal for a large online hypertext database that by 1991 had become what we now call the World Wide Web (Lawrence, Newton, Corbitt, Braithwaite, & Parker, 2002; Sklar, 2009). Thus the Web began as a means of improving information sharing and document handling between the research scientists at CERN and throughout the world. It was designed to allow pages containing hypertext to be stored in a way that allowed other computers access to these pages. It was probably not until about the mid 1990s, however, that the Web began to really gain in popularity. At that time, few could have foreseen the multitude of uses it would be put to by 2010, and the number of people who would make use of it. It is no exaggeration to say that the Web has now become quite ubiquitous.

The Internet has been around much longer of course, tracing its ancestry back to the ARPANET (Advanced Research Projects Agency Network), developed to link US Defense Department researchers with those in several universities in the USA. It became operational in late 1969 (Lawrence et al., 2002; Davison, Burgess, & Tatnall, 2008). The first appearance of the term ‘Internet’ was in 1974 as an abbreviation for ‘Internetworking’ (Network Working Group, 1974), and things developed from there, with electronic mail soon becoming an important form of communication within the research community that used this technology. At this time, however, making use of the Internet was not something that the average person or business could easily do or find much value in, and it was not until the later advent of the Web that use of the Internet became common, and a general topic of conversation in many communities.

No one knows exactly the size of the Internet, but an article in New Scientist (Barras, 2009) notes that back in 2005, Google estimated that the Internet contained 5 million terabytes of data. In July 2008 when the new search engine Cuil.com commenced operation claiming to be the world’s largest search engine, Google announced that it had registered a trillion unique pages, but in reality the Internet is probably even bigger than this as some estimates suggest that the pages indexed by Google and Cuil may represent only a hundredth of the information on the Internet (Barras, 2009). This same article suggests that 210 billion e-mails were sent every day in 2008.

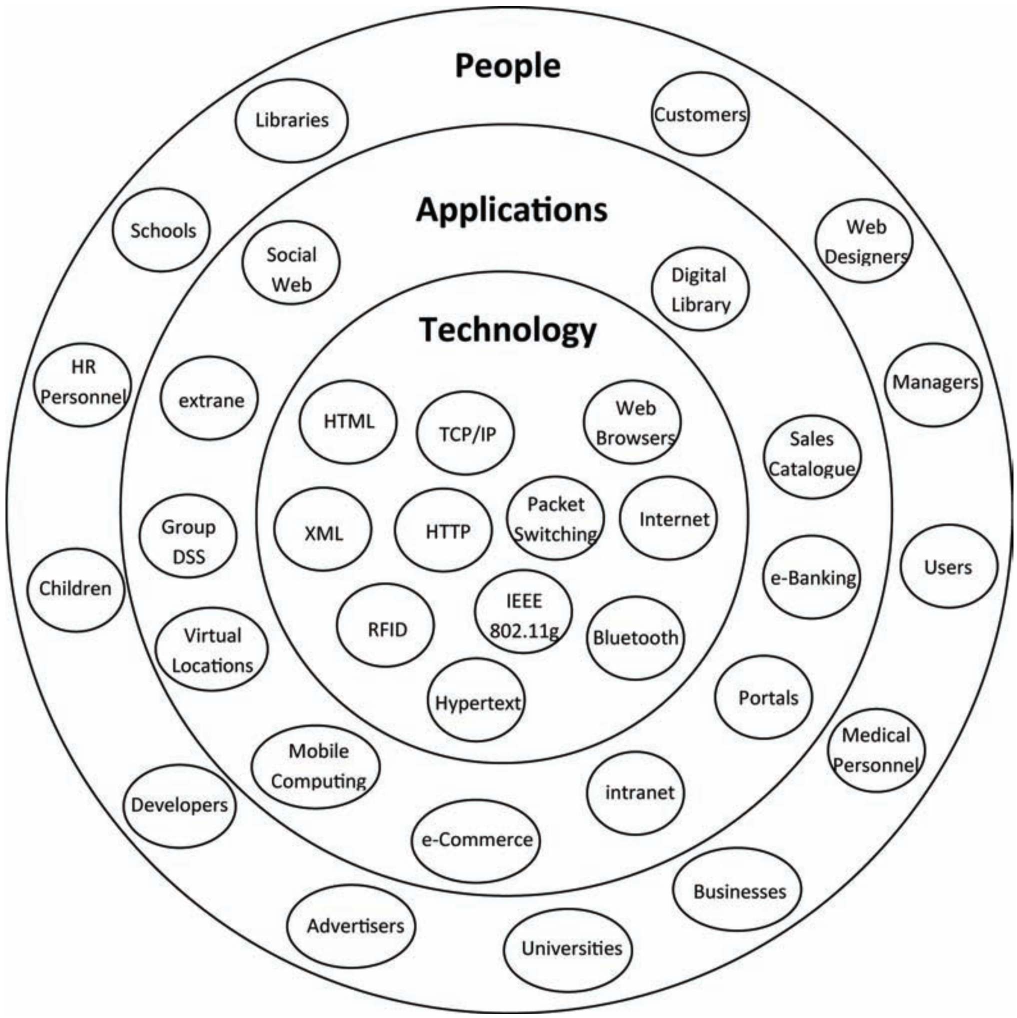
Today a great deal has been written about the Web, its concepts, its technologies, its design tools, its applications and the social and political effects that have gone with its growth. The Web is not, of course, just technology and the socio-technical nature of Web systems is an important consideration. For the purposes of this chapter, I will consider the study of Web-based systems and Web technology as consisting of three areas: technology, applications and people. Figure 1 (below) shows these as three concentric circles (with technology in the middle). Each of these circles then contains a number of entities related to that circle. (Space does not permit all relevant entities to be shown here.)

This introductory chapter will present an overview of these topics. Of necessity it cannot cover every topic fully and must be somewhat selective in its coverage with some topics only touched on and others omitted completely.

FUNDAMENTAL CONCEPTS

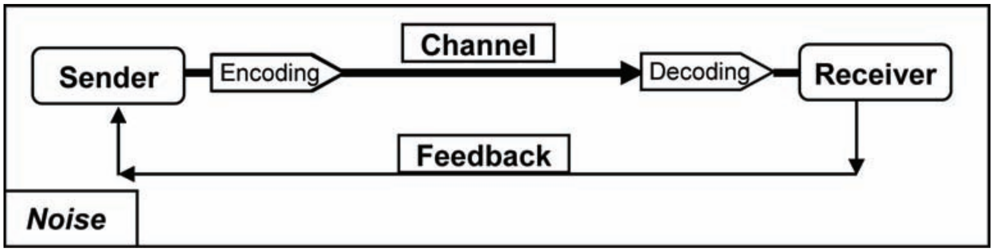
Both the Internet and the World Wide Web come with a large amount of jargon. Some understanding of this jargon and also of the concepts underlying web technology is necessary to fully appreciate the complexity and power of the Web. For those readers who may be new to some of these ideas, some of the main terms and concepts, along with a brief description of their meaning and use, will now be presented.

Figure 1. Components of web-based systems



- **Hypertext** allows words (or other objects) in one document to be linked to other documents. It provides a dynamic means of organising and accessing information where pages of information are connected together by hypertext links. A **Hyperlink** (Hypertext Link) can be text, or a picture that is associated with the location (path and filename) of another document and used to link to this other document. These documents are called **web pages** and can contain text, graphics, video and audio as well as hyperlinks. A **website** is a collection of related pages stored on a **web server**. A web server is made up of computer hardware and software, based on a PC or other larger computer.
- A **URL** (Uniform Resource Locator) gives the address or location of any specific website. Each URL defines the path that will transmit the document, the Internet protocol being used, and the server on which the website is located. Each Internet address is translated into a series of numbers called an **IP address**. A **domain name** is used by an organisational entity to identify its website and is based on the **Domain Name System** (**DNS**) hierarchy.

Figure 2. A Communication Model



- A **web browser** is a software application used to access and view web pages. Web browsers include: Internet Explorer, Firefox, Safari, Opera and Netscape Navigator.
- **Communications Model:** Communication involves a sender dispatching some form of message to a receiver. It occurs within a particular context or setting, and involves the transfer of some form of information from the sender to the receiver over some type of communications channel (Davison et al., 2008). The message is coded into an appropriate form by the sender before transmission, and later decoded by the receiver. Feedback lets the sender know how the message was received. Noise, or interference, can upset transmission and lead to the message received differing from the one that was sent.
- **Packet switching**. Data to be transmitted is broken into discrete packets consisting of groups of characters, which are then sent independently through whichever path between sender and receiver is most convenient at the time. The connection is virtual and so the data may follow different paths. Each packet is labelled electronically with codes to indicate its origin and destination, and may follow a different path through the network to that of other packets. When they reach their destination the packets are re-assembled to produce the original message.
- **Internet connection protocols**: instructions for connecting a computer to the Internet. Two important protocols are PPP (Point to Point) and SLIP (Serial Line Internet Protocol).
- **HTTP** (HyperText Transfer Protocol) is the set of rules that locate and move files of all types, including multimedia files, across the Internet. It does not process the packages of data it transmits but simply ensures they reach their destination and so defines computer links to the Web. **HTTPS** (HyperText Transfer Protocol (Secure)) indicates that HTTP is to be used, but with a different default port and an additional encryption/ authentication layer between HTTP and TCP.
- **Open Systems Interconnection (OSI)**. As networks operate in somewhat different ways, there was a need to define standards for data communication to provide a means for computers from different manufacturers to communicate with each other. Data sent over a network must arrive at its destination in a timely, correct, and recognisable format and to facilitate this, the OSI model consists of seven layers, each of which is selected to perform a well-defined function. While OSI is an international standard it is really more important as a concept and TCP/IP is the standard that is actually used.
- **TCP/IP** (Transmission Control Protocol, Internet Protocol). These are two protocols that support the basic operation of the Internet and include rules that computers on a network use to establish and break connections. TCP/IP controls the assembly of a message into small packets before transmission, controls the reassembly of packets once they reach their destination, has rules for routing individual data packages from their source to their destination and allows users to send and receive messages, find information, exchange data and download software.

- **HTML** (HyperText Markup Language) is used to describe how a web browser should display a text file retrieved from a web server. HTML defines how a page is displayed and is a derivative of **SGML** – Standard Generalised Markup Language which is a standard system (an ISO standard) used to specify document structure. HTML allows the developer of a web page to define hyperlinks between that document and any others that are required.
- **XML** (Extendible Markup Language) defines the page's actual content and also interprets the meaning of the data**.** It defines which data are displayed, whereas HTML only defines how a page is displayed. Elements of structured information include: content (pictures, graphics, text etc) and the role the content plays in the document; where the content is located in the document influences the meaning given to it.
- **XHTML** (Extensible Hypertext Markup Language) is a newer version of HTML, based on XML and designed to support newer devices.
- **Java** is a programming language used to create many web-based applications. Much of Java's syntax derived from C++ and its compiled version can run on any computer architecture in a Java virtual machine.
- An **intranet** is a private (internal) network accessible only by selected individuals within an organisation. It is based on web technology, but access is restricted so as to exclude the outside world. An intranet uses web browsers and hypertext links in the same way as the World Wide Web, the only real differences being where the web pages are located, and who can access them. (Applications of intranets are discussed further in a later section.)
- An **extranet** is a private network (based on web technologies) that links selected parts of a company's intranet with its customers, suppliers, or other authorised business partners. (Applications of extranets are discussed in a later section.)
- **EDI** (Electronic Document Exchange) is the exchange of data or 'business documents' directly between computer systems in business partner companies using a standardised data format. It has been used for more than 30 years predominantly for purchasing and inventory. This direct computer-to-computer form of EDI has, to a large extent, now been superseded by web-based purchasing systems.
- **RFID** (Radio Frequency Identification) is a technique for storing and retrieving data remotely using devices called RFID tags that can be attached to, or inserted into a product. An RFID tag incorporates a silicon chip and antennae that can broadcast a unique identification code when prompted by a reader device.
- **Bluetooth** is an open standard for short-range wireless communication (up to 10 metres) between digital devices. It comprises hardware, software and interoperability standards, protocols and requirements and is implemented through a small, low-cost radio chip that can be incorporated in mobile phones, PDAs, pocket PCs, computers, printers and similar devices. (It was initially developed by Ericsson and is named after Harald Bluetooth, a Viking and the King of Denmark between 940 and 981.)
- **The IEEE 802.11 Protocols**. The Standards Association of the Institute of Electrical and Electronic Engineers (IEEE) has developed a series of standards for wireless local area network (WLAN) devices operating in close proximity (up to 100m) under the generic title **IEEE 802.11**. There are a number of variants of this protocol, such as **IEEE 802.11a**, **IEEE 802.11b** and **IEEE 802.11g** (Wave Repo2001; O'Hara and & Petrick, 2005).
- **PDA** (Personal Digital Assistant). Sometimes now called a **Smart Phone**, these devices offer many of the communication and information characteristics of a laptop computer and mobile phone incorporated into a single device. Often a PDA includes a mobile (cell) phone along with Windows

Mobile operating system with mobile versions of Word, Excel and Outlook, Bluetooth and IEEE 802.11 connectivity and Internet access.

- **Personal Area Networks** (PAN) are ad hoc networks of personal digital devices such as laptop computers, personal digital assistants (PDA) and mobile phones able to transfer data and linked to other personal digital devices by Bluetooth, or some other wireless technology.
- The **Semantic Web** offers a common framework for data to be shared and reused across application, enterprise, and community boundaries. The World Wide Web Consortium (W3C), who are developing the Semantic Web, note that it is concerned with common formats for the integration and combination of data from diverse sources and the language needed to show how this data relates to the real world (http://www.w3.org/2001/sw/). It is an extension of Web in which the semantics of information and services on the web are defined. This then makes it possible to understand requests of people and machines who want to use web content.
- **Web 2.0** websites build on the interactive facilities of the Web and so allow users to do more than just retrieve information. This has led to the development of web-based communities and social-networking sites.
- **Internet service provider** (ISP). This is a company that offers its customers access to the Internet
- **Web hosting service provider**. These organisations provide space on their server for an organisation or individual's web page. They also offer connectivity of their servers to the Internet.
- **Social networking** sites (such as Facebook, MySpace, Twitter and LinkedIn) aim to build online communities of people who share interests. (Social networking is discussed more fully in a later section.)
- A **Wiki** is a website that allows the easy creation and editing of a number of interlinked collaborative pages. The Wikipedia encyclopedia is one of the best-known of these wikis (http://en.wikipedia.org/wiki/Wiki).
- A **Blog** (short for weblog) is a website set up by an individual to describe events and materials of interest to them and relevant to their life.

DEVELOPMENT AND DESIGN METHODOLOGIES AND TOOLS

Web development and design has much in common with the design of other information systems and a starting point should be in process of analysing and creating information systems (Tatnall, Davey, Burgess, Davison & Wenn, 2002). Creating an information system and getting it working can be considered to comprise three separate aspects:

- **Systems analysis:** the description of a logical model of the present or proposed system in non-technical terms, independent of the actual physical implementation.
- **Systems design:** the business of converting this logical model into a useable system.
- **Systems implementation:** involves the construction of the physical system to the level of hardware acquisition, programming and change management.

Web Development Issues

As many books describe the development of information systems I will say no more about this here. Web development, apart from following the logical process of information systems development, involves a number of other special considerations and I will briefly discuss some of these now (Sklar, 2009).

- Connection speed considerations. Will all your users have high speed broadband connections? If some are likely to be still using modems then the amount of data to be downloaded needs to be limited or else it will take too long to load and the potential user will give up.
- Different screen resolutions. Not all users will have the latest high resolution monitors and there perhaps need to be different version of the site for different monitor resolutions.
- Different operating systems (– Windows, Mac, Linux etc) and different web browsers may make your site appear differently. This needs to be taken into consideration and portability of design is a worthwhile goal.
- Design with the user in mind. This seems obvious, but is not always done. Consider the path taken by the eye in looking around the web page. Consider use of language appropriate to the intended user. Apart from whether the language is English, French, Spanish, German or Chinese, there is the issue of complexity – will the intended user understand? Another issue here is ensuring that users can find their way around inside the website hierarchy. The basic point here is that the website must be easily usable.
- As different cultures around the world see and understand things somewhat differently, creating different pages for different countries, as do many commercial websites, is worthwhile both from the language to be used and because different countries many need slightly different content.
- Accessibility is important. Consideration should be given to people with disabilities such as poor eyesight, colour blindness, poor hearing etc.
- Programming issues have much in common with those in information systems, except that the appropriate languages are often different.
- File and data structures – again, approaching this issue has much in common with similar issues in building an information system.
- Building a website needs graphical design capabilities as well as abilities in information systems design.
- Security. It is important that appropriate security is built into any website, relevant to the use that will be made of this site.
- Privacy of users of the website should be respected by not collecting unnecessary personal data and being careful not to pass on any data that is collected.
- Trust will be built up with website users if the site shows that it deserves such trust.
-

Web Development Tools

A multitude of different tools and commercial products exist to help with website creation which can be considered at two levels: design of the underlying code, data and file structures and design of the appearance of the screen itself. One level needs an information systems professional, the other someone with graphic design training and abilities. To create the code there are programming languages such as Java, C++ and Visual Basic and to create or edit graphics there are packages such as Photoshop or Dreamweaver.

One web development product is Microsoft Visual Studio with Visual Web Developer which includes a number of relevant different programming languages such as C++ and Visual Basic, and other tools useful for website creation. At another level, Microsoft Office Front Page and Expression Web allow website creation without the need for coding.

WEB-BASED APPLICATIONS

Since the start of its rapid growth in popularity in the mid 1990s, a huge number of web-based applications have been developed. It is, of course, impossible to describe even a small fraction of these but I will discuss just a few of the most interesting in this section.

E-Business (E-Commerce)

E-Business or electronic business (sometimes called e-Commerce) can be defined as the use of electronic means on the Web to conduct the business of buying and selling using websites with shopping carts and e-mail. This can involve many facets of a firm's operation being conducted electronically between the business and its partners, suppliers and customers (Davison et al., 2008). This is a very broad topic containing many sub-areas and represents a major use of the Web.

E-Commerce Business Models

There are several commonly described models that relate the electronic commerce aspects of a business to other entities of importance:

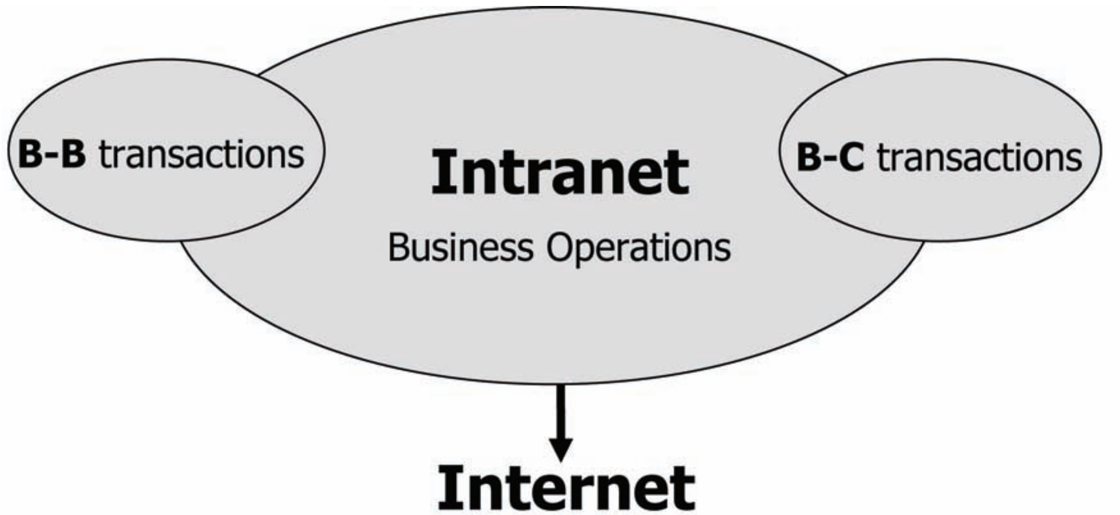
- Business-to-Business (B-B), for transactions conducted between businesses.
- Business-to-Consumer (B-C), for consumer shopping on the Web.
- Business-to-Government (B-G) is one of several other models used to connect to other entities.
- Business-to-Employee (B-E). Business operations within an organisation (such as B-E) often make use of the organisation's intranet.

E-Marketplace

A traditional approach to advertising using well known advertising media such as radio, newspapers and television is know as the 'Mass Media Model'. The key to this approach is that marketing campaigns were typically saturation campaigns that were designed for exposure to a large group of people, with the hope that a number of them would then purchase the product (Davison et al., 2008). On the other hand a 'Hypermedia Computer-Mediated Environment' represents a many-to-many communication model for an environment such as the Web where interaction between businesses can communicate with customers via a website or automated e-mail system without necessarily conversing with them directly (Hoffmad & Novak, 1996).

At the business-to-consumer level it is possible to purchase almost anything on the Web. One of the first major businesses to make use of the web was Amazon.com, launched in 1995, but since that time many other businesses have looked carefully at this business model and made use of it. The website of the UK government organisation Businesslink.gov.uk suggests that there are many different types of e-

Figure 3. E-Business and Web Technologies



marketplace. They note that these are based on a range of different business models and can be broadly divided into categories as follows:

- **Independent e-marketplace** – usually a B-B online platform operated by a third party that is open to buyers or sellers in a particular industry. To participate, some form of payment is usually required. It allows the business to access requests for quotations or advertisements in their relevant industry sector.
- **Buyer-oriented e-marketplace** – normally run by a consortium of buyers to establish an efficient purchasing environment. This can help the buyers lower their administrative costs and obtain better prices from suppliers. Suppliers can use this sort of website to place their catalogues for relevant customers.
- **Supplier-oriented e-marketplace** – set up and operated by a group of suppliers seeking to create an efficient sales channel to a large number of buyers. This often provides buyers with information about suppliers, particularly those they may not be familiar with.
- **Vertical e-marketplaces** provide online access to businesses of a particular industry sector. These include the chemical, construction, automotive and textiles industries. The advantage for suppliers in using a vertical e-marketplace is that this can increase operating efficiency and help to decrease supply chain costs, inventories and cycle time.
- **Horizontal e-marketplaces** are able to connect buyers and sellers across different industries or regions.

Online auctions where people and businesses can buy and sell a variety of goods and services are another form of e-Marketplace and eBay is a popular example of such a site. On eBay most sales take place through a set-time auction format, but other approaches are also used.

Many large retail stores also make use of the Web to both advertise and also sell their products. Before the advent of the Web telephone shopping was quite popular and allowed a number of businesses that were too small to afford their own retail premises to do business from a private home or other premises. The e-marketplace of the Web has meant a decrease in shopping of this sort but this has been replaced by a huge increase in the use of the Web by these small businesses. For a small business, the costs of having an online operation can be much lower than setting up a shop and many new 'virtual enterprises' are now operating in this area. Paying for purchase or goods or services on the Web can be facilitated by systems such as PayPal (and Paymate in Australia) that can act as an intermediary providing secure financial transactions to collect money from the buyer and pass this on to the supplier.

Travel Industry Information and Booking Services

In times past it was necessary to go to a travel agent for booking of hotels and flights, particularly if they involved international travel. The Web has changed all this with booking and information services readily available for many hotels and all but the smallest airlines. These services could be considered under the heading of e-Marketplace, but as they involve more than just the purchase of services and also provide information I have put them into a category of their own.

E-Banking

Daniel (1999) describes Internet banking as the provision of banking services to customers through Internet technology. Karjaluoto, Mattila and Pento (2002b) indicate that this involves the provision of banking services such as accessing accounts, transferring funds between accounts, and offering an online financial service. Use of web technology in the banking industry can thus be defined as the accessibility

Figure 4. IEEE Computer Society Digital Library Portal

and exchange of banking services and/or banking communication technologies on websites available through the World Wide Web by utilising Internet technology (Al-Hajri, 2005).

Karjaluoto et al. (2002a) then identify two significant benefits that may be gained from Internet banking:

- Benefits for the banks include a reduction in transactional costs along with the ability to reach customers anywhere.
- Benefits for customers include being able to take full advantage of various banking services available online.

Although e-Banking is now common in the developed world, this is not so much the case in developing countries. A recent exploratory study (Al-Hajri, 2005) of the uptake of Internet banking in Oman (a developing country) found that in Oman, the bank managers' perceptions of four issues: relative advantage, organisational performance, customer/organisational relationship and ease of use jointly provided a broader understanding of Internet technology adoption in the banking industry.

Digital Libraries

A digital library could be described as: "an information system that supports the access, retrieval, selection, organisation and management of a focused collection of multimedia objects" (Goh, Theng, Lim, Zhang, Chang, & Chatterjea, 2007). A digital library offers access to collections of selected and organised digital resources. These resources include books, journal articles and photographs (McCarthy, 2007) and a digital library's main advantage over physical libraries lies in their ease of access. Many cultural and historical associations as well as professional societies such as the IEEE Computer Society (http://www2.computer.org/portal/web/csdl) and Association for Computing Machinery (ACM) (http://portal.acm.org/portal.cfm) and the Project Management Institute (http://www.pmi.org/Resources/Pages/) have their own digital libraries.

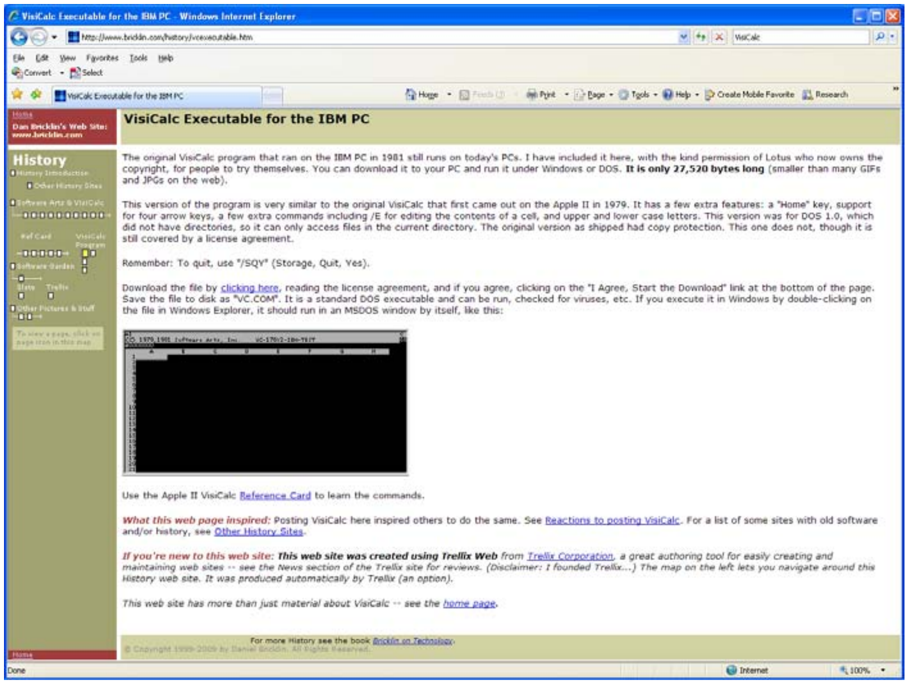
Virtual Machines and Locations

Colossus was, arguably, the world's first electronic digital computer and was used in Bletchley Park in the United Kingdom to break German military codes towards the end of World War II. A simulation of using Colossus to break the German Tunny code (Sale, 2006) is available from the Web at: http://www.codesandciphers.org.uk/anoraks /lorenz/tools/index.htm This is just one of the examples of virtual machines or operations, another is a simulation of VisiCalc, the first electronic spreadsheet which can be downloaded from: http://www.bricklin.com/history/vcexecutable.htm

The Web also offers access to a number of virtual tours of interesting locations. One such virtual tour is of the Italian city, Pompeii: http://www.italyguides.it/us/napoli/ancient_roman_city/virtual_tour_of_pompeii.htm. Another example is a tour of the Louvre Museum in Paris. This is available at: http://www.louvre.fr/llv/musee/visite_virtuelle.jsp?bmLocale=en

Each of these examples could have been accessed from files on a purchased CD, but being able to access them on the Web is yet another reason for the Web's popularity.

Figure 5. VisiCalc executable on a PC



Web Search Engines

The ability to obtain information has in the past involved going to a library and searching for this in a number of books. While that is still a worthwhile activity, it takes a good deal of time and search engines like Google, Cuil and Bing offer a much faster alternative. The convenience of using a Web search engine to find information or the answer to a question is such that people talk about 'Googling' the question and the verb 'to Google' has entered our vocabulary. There are also related specialist search engines such as Scholar Google, Google Images and Google Video. Not a lot needs to be said about search engines as they are so well known, except to remark on their power and on the huge impact they have had on our lives.

Web Encyclopaedias

An encyclopaedia in book form was (and still is) an extremely expensive purchase that many families felt obliged to make to help their children with their school work. While the book version is still useful and worth having, the online encyclopaedia has made accessing information ever so much easier. Products such as Wikipedia (http://en.wikipedia.org) have made a fundamental difference to accessing information by putting this in everyone's reach. Other Web encyclopaedia products include Encarta (http://encarta.msn.com/), Britannica online (http://www.britannica.com/) and Webopedia (http://www.webopedia.com/).

Web Portals

Web portals are now ubiquitous and researching their use in organisations and by individuals is important (Tatnall, 2007b; Tatnall, 2009d). To illustrate the wide range of sometimes quite specific applications now being filled by portals, the following list of topic categories (Tatnall, 2005) is taken from articles by the large number of academics and practitioners from around the world who contributed to the *Encyclopaedia of Portal Technology and Applications* (Tatnall, 2007a).

Portal Concepts, Design and Technology

As one might expect, portal concepts are an area of particular interest with topics such as: what is a portal? benefits and limitations of portals, comparing portals and web pages, evolution of portals, factors affecting the adoption of portals using activity theory, information visualisation, the ubiquitous portal, and portals of the mind (Tatnall, 2009d).

Research on portal design and technology also features prominently with topics such as: collaborative real-time information services via portals, digital interactive channel systems and portals, designing spatio-temporal portals for continuously changing network nodes, dynamic taxonomies and intelligent user-centric access to complex portal information, factors affecting portal design, developing semantic portals, an evolutionary approach to developing on-line learning portals in low bandwidth communities, the role of ontologies in portal design, Java portals and Java portlet specification API, large-scale ASP replication of database-driven portals, WSRP specification and alignment with JSR 168 portlet specification and user-centric knowledge representation for personalisation of Web portals.

Portal Implementation

As well as the technology itself, there needs to be some consideration of issues involved in the organisation implementing its portal application (Tatnall, 2009b). Whether the portal is based on a commercial product or if it is programmed from scratch is itself an important implementation issue. Research issues involved in the implementation of portals in specific organisations are another point of interest with topics like the following: evaluation of Web portals, portal quality issues, economical aspects when deploying enterprise portals, e-management portals and organisational behaviour, user acceptance affecting the adoption of enterprise portals, enabling technology and functionalities of shopping portals. Articles dealing with implementation issues often involve a case study of the organisation implementing the portal and discuss the goals and intentions of using a portal, how the technology was chosen, the implementation approach used and the problems incurred during the implementation. Not all implementation issues, of course, are technical ones as implementations all involve people.

Portal Uses and Applications

The largest area of research interest is in how portals are applied and used, and most of this research refers to quite specific applications such as: the Bizewest portal, the Bluegem portal, the European quality observatory portal, the future of portals in e-science, hosting portals on an e-marketplace, how corporate portals support innovation, how the Internet is modifying the news industry, industry portals for small businesses, portals for business intelligence, strategic planning portals, study of a wine industry portal, supplier portals in the automotive industry, supply chain management and portal technology, portal economics and business models, portals for integrated competence management, cultivating memories through the Beijing Olympics (2008) Advertainment portal, portals for workflow and business process management, project management Web portals, provision of product support through enterprise portals, employee self-service portals, a generic model of an enterprise portal, portal technologies and executive information systems implementation, the role of portals in consumer search behaviour and product customisation, guided product selection and comparison of e-commerce portals, business challenges of online banking portals, Web museums, Web portals as an exemplar for tourist destinations and a Web portal for the remote monitoring of nuclear power plants (Tatnall, 2009d). Within this area of applications it is possible to identify a number of major topics of interest. These are:

- **Education Portals**. Specific example include: academic management portals, large scale integrated academic portals, mobile education portals, artificial intelligence and education portals, high school portals, primary school portals, corporate e-learning portals, Weblogs, knowledge portals in education, and subject teaching portals.
- **Health and Medical Portals** examples include: empowerment and health portals, bioinformatics portals, biotechnology portals, nursing knowledge portals, network-centric healthcare and the entry point into the network and genomic and epidemiologic medical data portals.
- **Community Portals**. Topics researched in this area included: how to promote community portals, a community geographic domain names portal, designing a portal and community-community generator, local community Web portals and small businesses and the paradox of social portals.
- **E-Government Portals**. This is an area related to Community Portals and there was much research interest in government portals around the world. There were topics such as: portals in the public sector, e-government portals, e-value creation in a government Web portal in South Africa, government portals as a gateway for enhancing electronic governance in Singapore, interoperability integrating e-government portals, modelling public administration portals, service quality in the case of e-government portals, and state portals as a framework to standardise e-government services.
- **National Portals**. There is also important research into portals related to national issues: African Web portals, business module differentiation and a study of the top three Chinese portals, cross-cultural dimensions of national Web portals, growth of e-portals in Dubai, how portals help Chinese enterprises operate successfully in global markets, impacts and revenue models from Brazilian portals, Web museums and a case study of the French population.
- **Personal and Mobile Portals** is an area of growing interest as mobile technology continues to mature. Examples of this area are: accessible personalised portals, mobile portal technologies and business models, mobile portals as innovations, mobile portals for knowledge management, the MP3 player as a mobile digital music collection portal, widgets as personalised mini-portals, wireless local communities in mobile commerce and portals supporting a mobile learning environment.
- **Knowledge Management, Libraries and Professional Societies**. Knowledge Management, especially relating to libraries and professional societies is another area which attracts a number of researchers. They were interested in topics such as: designing portals for knowledge work, mobile portals for knowledge management, knowledge servers, the portal as information broker, portal strategy for managing organisational knowledge, a prototype portal for use as a knowledge management tool to identify knowledge assets in an organisation, library portals and an evolving information legacy, open access to scholarly publications and Web portals, the IFIP portal, and the portal features of major digital libraries.

Intranets

The term Enterprise Information Portal (or sometimes ‘corporate portal’) can be applied to the gateways to corporate intranets that are used to manage the knowledge within an organisation (Davison et al., 2008). These are often designed for business-to-employee (B-E) processes that offer employees a means to access and share data and information within the enterprise. An intranet offers a number of useful applications:

- **Access to company documents** such as minutes of meetings, forms, policies, procedures, phone lists, information documents, documentation and archived information.
- **Software access and download**. Access to common software applications (on a central server), software downloads, software updates (including anti-virus software).
- **Services** such as information and communications technology (ICT) technical support and diagnosis, training materials and on-line training, human resource data (e.g. leave entitlements), search facilities to search the site for a specific item.
- **Communication** – broadcast company information or policy, bulletin boards, chat, electronic mail, newsgroups, on-line meetings, video conferencing.
- **Consistent front-end to software applications** – single point of access to other systems, consistent interface to other systems, complexity of databases and applications is hidden, front-ends to legacy systems.
- **Links to outside systems** – the Internet, the company extranet (and possibly to business partner’s systems).

Extranets

Extranets have a number of uses including replacement of direct computer-to-computer Electronic Data Interchange (EDI). These extranets can use Internet technology to perform the same transactions, although sometimes rather more slowly. Extranets can also be used to assist with Supply Chain Management. A supply chain links manufacturers, retailers, customers and suppliers and involves the co-ordination of order generation, order taking, order fulfilment, order distribution and information sharing. Access by business partners to parts of the organisation’s intranet can be used to facilitate this process.

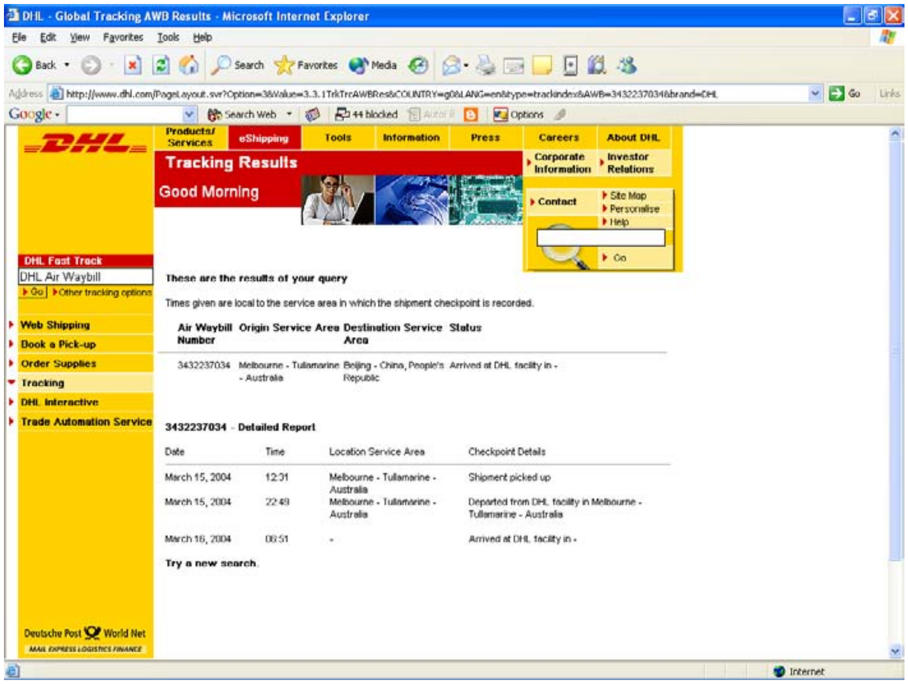
An extranet can also be used to facilitate ‘value added marketing’ as the organisation’s Web site will have basic information of interest to its customers. There may, however, be situations where it is useful to allow a customer access to its core systems to obtain, for example, account information. Another example is that a computer supplier may provide (password) extranet access to its own library for important customers.

Before the Internet, freight delivery companies like DHL (www.dhl.com.au) needed to spend a lot of time on the phone telling customers the location of their deliveries. It then occurred to someone that it would be better to let their customers see this for themselves by offering (limited) access to their own internal systems via an extranet.

Communication

The best know form of communication offered by the Web is, of course, e-mail. This is so well know to most people that I will say no more about it here except that it was available on the Internet before the Web came into existence, but was then much more difficult to use.

Figure 6. DHL's parcel tracking extranet



Another form of Web enabled communication is Skype (http://www.skype.com/intl/en/) which is a software application that enables its users to use the Internet to make almost free phone calls. Skype uses a proprietary form of Voice over Internet Protocol (VoIP) that allows the call to make use of the Internet rather than the normal phone system. Skype also offers other features including video conferencing and instant messaging.

Chat rooms are another form of communication and are offered by a number of companies. These include: Yahoo (http://messenger.yahoo.com/features/chatrooms), Match.com (http://www.match.com.au), Google Talk (http://www.google.com/talk/) and Gmail (http://mail.google.com/mail/help/chat.html). Chat simulates face-to-face communication in that the topic can be anything that the chatters want it to be and people can come and go at will. One big difference, however, is that Web chat is anonymous in many cases. In this respect it is a form of communication that is particularly related to the Web.

Group Decision Support Systems

Applications like Google Groups (http://groups.google.com/) and Yahoo Groups (http://groups.yahoo.com/) offer the possibility for groups of people to easily communicate with each other by e-mail. While this does not directly offer decision support, it does achieve part of this in allowing a group of people to communicate easily and discuss the topic under consideration.

A number of researchers have investigated Web-based group decision support systems (GDSS). Abdelhakim and Shirmohammadi (2007), for example, discuss a Web-based GDSS that can be used to select and evaluate educational multimedia and Ma, Quan and Zhiping (2009) describe a Web-based GDSS for Research and Development project outcome assessment in government funding agencies. The company DSS Resources (http://dssresources.com/) offers more product advice in this area.

The Social Web

The Web has also opened up a wide range of possibilities for people to socialise remotely in various ways. Whether socialising via the Web is a good thing or not rather depends on your point of view and I will come back to discuss this later.

Facebook (http://www.facebook.com/) is perhaps the most commonly known social networking Web site. It is designed so that people can join a network organised by their school, workplace, region or other similar entity and then interact with other people in this same network. They can then create their own personal profile, notify other people about themselves and send and receive messages from these people.

MySpace (http://www.myspace.com/) is another social networking Web site that offers similar facilities to Facebook.

LinkedIn (http://www.linkedin.com/) is a business-oriented social networking Web site that is mainly used for professional, rather than personal, networking.

Twitter (http://twitter.com/) is another social networking Web site that is used to send and receive short (140 character) text messages called tweets. These are displayed on their author's profile page and sent to other subscribers (know as followers). Twitter users can send and receive their tweets on their mobile phones using SMS (Short Message Service).

Another more specific example is **Academia.edu** (http://www.academia.edu/) which is designed, as its name suggest, to link academics and researchers.

YouTube (http://www.youtube.com/) is a video sharing Web site where users can upload and share videos they have made. These can be viewed on a PC in MPEG-4 format.

e-Learning

Electronic learning (e-Learning) involves support of learning using Web technology as the medium for teaching. In some cases, especially where the students are at a location that is remote to the teaching institution, it is used to replace face-to-face teaching entirely. In other cases it is used to supplement classroom learning. This form of teaching is used in universities and some schools, but also for training in many large companies, and particularly in companies whose operations span the globe. The largest provider of e-Learning applications is Blackboard Inc (http://www.blackboard.com/) whose products include WebCT and Blackboard. These products typically offer the facility for discussion boards, e-mail systems, live chat, Web pages and downloading content including documents. An alternative open source e-learning package is available from Moodle (http://moodle.org/).

For the student, one big advantage of e-learning is that they do not need to attend the teaching institution in person but can undertake their studies from home or their place of employment. When combined with mobile computing the possibilities for undertaking learning at any time and any location are great.

Mobile Computing and the Web

While mobile computing relates not only to the Web but also to other aspects of computing, it is particularly relevant to discuss this here as it offers the possibility of viewing Web content at any location. Few people would now question the idea that computers and communications devices can be small enough and mobile enough to use anywhere, but this has not always been the case. The first computers were huge machines filling whole rooms and weighed several tonnes and telephones were anything but portable until quite recently. Laptop and net computers, Personal Digital Assistants (PDA) and smart phones are now so small as to be extremely portable, but it is not just the hardware here that is significant but also the protocols for short-range radio communications that they require. There are two main existing standards for short-range radio communications (Davison et al., 2008):

- **IEEE 802.11** (WiFi) is a set of standards for wireless local area networks, developed by IEEE, that operates in the 5 GHz and 2.4 GHz public spectrum bands over a 50-100 metre radius at a maximum data transfer rate of up to about 50 Mbps.
- **Bluetooth** offers a 10 metre range with a peak data transfer speed of 1-3 Mbps. It is possible to operate at least ten Bluetooth devices within a 10 metre radius. Bluetooth provide a means of linking digital devices into Personal Area Networks (PAN)

Each of these protocols offers the possibility for a portable device to link to other portable devices or to access the Internet at almost any location. In city areas a number of retail premises (including McDonalds) offer free Internet WiFi 'hot spots' where customers (and those nearby) can gain access to the Internet for no cost using an IEEE 802.11 protocol in their laptop. Other locations, including most hotels, also offer wireless Internet access but at a cost.

The important point here is that these mobile devices, in conjunction with a WiFi protocol, make it possible to access the Web from almost any populated location.

Web-Based Gambling

While not permitted in some parts of the world, in others online gambling is perhaps being used at times to circumvent local gambling laws or at least to make it much easier for gamblers to indulge in this activity. Sites such as Web Gamble (http://www.webgamble.org/) and Wager Web (http://www.wagerweb.com/) are just a few of many sites that offer this facility. The Casino Gambling Web site (http://www.casinogamblingweb.com/) provides news reports and information about online gambling. For those with a gambling problem Gamblers Anonymous also has its own Web site (http://www.gamblersanonymous.org/).

ORGANISATIONAL, MANAGERIAL, SOCIAL AND POLITICAL IMPACT OF WEB TECHNOLOGIES

Organisational and Managerial Impacts

Are organisations different to manage when they make extensive use of the Web? The answer is in most ways that they are not, but there are some issues of which a manager must take account. I will mention just a few. The first is the ease of access to information by both employees and customers. An organisation can make good use of the ease with which it and its employees can gain information, but sitting an employee in front of a computer to search can also be a very time wasting exercise and it is important that proper goals and time limits are set for this type of activity. That customers can also easily obtain information about competitors and other products can be a problem which must be recognised by a business. Steps need to be taken to become aware of this problem and to seek means to overcome it

At a different level another managerial issue is in the use of an organisational intranet. It is quite easy to set up an intranet that can be used to store all sorts of company documents such as: policies, forms, procedures, minutes of meetings, internal phone lists and so on. While in the past it was necessary to distribute these documents in paper form they can now be put on the intranet and made easily available to all staff. There will now be no excuse for someone claiming ignorance of a company procedure or policy because they could not get hold of a copy of it. The intranet can also be used to broadcast messages from the CEO or other senior managers to all employees. If not abused this can be a very useful facility. Updates and patches for computer software can also be delivered in this way, making it possible for the organisation to keep much more up to date.

It is sometimes claimed that if some information, such as a catalogue or price list, is on the organisation's Web site then it must be up to date. This is, of course, absolute rubbish and a better claim is that if it is on the organisation's Web site then there is the *possibility* that it is always kept up to date. This possibility will only eventuate however, if it is *someone's job* to keep information on the company Web site up to date.

Another exciting management possibility with use of the Web is the creation of a virtual enterprise. Such an organisation does not need a shop front to interact with its customers but can order and supply its products remotely. Managing such an enterprise, where some employees operate from one location and others operate from different locations is quite different to running a business located under one roof and needs quite a different management style.

Social and Political Impacts

In common with the introduction of most new technologies, the advent and growth of the Web comes with the dual possibilities of good or ill ey and & Tatnall, 2007). Along with freedom in the transmission of knowledge comes a loss of control for authorities and the possibility of chaos. The introduction of Guttenberg's printing press in circa 1455 allowed mass production of the Bible and eventually changed the nature of Christianity in Europe. For many years printing was the technology used to distribute information. The came the telephone, and this technology allowed people to keep in contact remotely and to distribute news and information. The Web furthered this democratisation of information and allowed people to spread news and to keep in touch without the need to go through any official or governmental channels. Censorship and control of the Internet in some countries is another hot issue that is unlikely to go away. George (2005) suggests that the relationship between new technological media and political factors is far too dynamic and interdependent to be reduced to simple causal statements. He suggests that the less democratic the society, the more attractive the Internet looks as an emancipatory medium, but the more likely radical Internet use will be blocked or punished.

The role of the Internet in mobilising and assisting various protest movements is an interesting topic. Stohl and Ganesh (2009) note the importance of the Internet for spreading information, organising and constructing networks and forming individual and group identities. They also suggest that it can even act as a form of protest itself. An article in the Wall Street Journal (Qiang, 2005) discussed the role of the Internet in organising protests in China in 2005. The article noted that "the most fervently pro-nationalist segment of society overlaps demographically in China with those who spend the most time on the Internet, since both are primarily composed of young, educated, urban males" and goes on to describe how recent protests were almost exclusively organised using the Web.

The Internet & Democracy Blog (http://blogs.law.harvard.edu/idblog/2009/04/07/moldovan-youth-organize-protests-with-twitter/) describes how Moldovan youth organised protests with the aid of Twitter. It describes how Twitter not only helped rally protesters but also provided a real glimpse of what was happening on the ground. Debate also has been progressing on the role of technology in Thailand's recent protests (2009) http://neteffect.foreignpolicy.com/posts/2009/04/17/technologys_dubious_role_in_thailands_protests.

How use of the Web affects democracy and political activities is an interesting and evolving study. One example is that in recent elections in Australia both the Prime Minister (at the time) and the then Leader of the Opposition made considerable use of YouTube to spread their message. Similar use of technology also occurred in other countries and no doubt we will see an increase in the use of Web technologies of all types in the political process. A detailed study in Korea undertaken by Woo-Young (2005) found that citizen e-participation was characterised by: convenient access to detailed information, free expression and exchange of opinions, online activism led by politicised agenda and active formation of cyber groups. Woo-Young notes that Internet political portals are not connected with existing political power and capital, and that they facilitate communication between citizens.

Hutchins and Lester (2006), however, suggest that the use of the Web by environmental groups is an example of mob rule. The existence of a Web portal does not indicate the number of people subscribing to the philosophy of its owners. The Web site allows coordination of efforts, such as protests, in a way that may make the actions of a group look more important than the size of the group might support.

Francis Bacon is credited with the expression 'Knowledge is Power' and the growth in use of Web technologies has brought this to the fore with the creation of new classes of information rich and information poor depending on their access to this technology. Access to huge amount of information is now possible, much than anyone could have dreamed of a few years ago. With access to the Web many people now also have access to encyclopaedias, news, research results and much more. Those without access to the Web miss out.

Undesirable Impacts

There are also many undesirable impacts of the growth of the Web. Many people would see the increase in Internet gambling as one of these and most would see as a bad thing the Web's role in making much easier the dissemination of pornography. Theft and fraud resulting from improper Internet financial transactions are a major problem, and identity theft has been made easier by the increase in general use of the Web.

Another problem in general use of the Web is the increased possibility of misinterpretation of information. Medical Web sites abound on the Internet with almost every major disease being represented by at least a support group portal. These Web sites offer everything from emotional support and possible treatment advice to contacts within the medical community (Davey & Tatnall, 2007), but this is not always seen as useful and Theodosiou and Green (2003) identify five important problems with patients using medical portals to satisfy their needs:

- Potentially dangerous drugs and other substances may be bought by individuals for themselves or their children.
- Individuals can spend a lot of money on products or diagnostic procedures that have no scientific backing or benefit.
- The information may be more negative than the reality of the situation.
- Individuals may abandon treatment programmes of proven efficacy to pursue less-mainstream approaches.

Information that had previously been sold by its originators soon began to be dispersed without charge via the Web and the owners of the software, music and videos being freely distributed invented the term Internet piracy. Yar (2005) indicates the size of the possible loss to copyright owners in terms of billions of dollars. Plagiarism is another evil that has been made much easier and more common by use of the

Web. When it is so easy for a student to copy a passage from a journal article found in a digital library and paste it into their essay it is little wonder that plagiarism has become a major problem in universities and other educational institutions.

Finally, there is the question of whether spending large periods of time in front of a computer should be seen as a non-human activity that discourages normal social interaction. While the use of social networking sites offers many possibilities for social interaction of a sort, unless this is followed up by face-to-face contact of the normal type there could be something unhealthy about this use of the Web.

THE SOCIO-TECHNICAL NATURE OF WEB SYSTEMS

Sometimes those of us who design information systems of any type get lost in the elegance and intrinsic worth of our design efforts and forget that for an information system to have any value, it must first be adopted and put into use. There is an old Anglo Saxon saying that 'You can lead a horse to water, but you can't make it drink', and something similar can be said about the adoption and use of information systems. Because of their human and non-human aspects, Web-based information systems should be considered as socio-technical entities, and it is most important that both of these aspects are kept in mind throughout the process of systems design and implementation. This is especially true of Web-based information systems.

Building any type of information system is a difficult task, partly due to the problems in ascertaining the requirements of the intended users, but also because of the complexity of the large number of human-machine interactions (Tatnall & Davey, 2005) that such systems typically involve. This complexity is reflected in the difficulty of building these systems to operate free from error and to perform as intended (Tatnall, 2009a), and building Web based systems is no less complex.

The Information Systems (IS) discipline is primarily concerned with the ways that people build and use computer-based systems to produce useful information. It thus always has to deal with issues involving both people and machines, and with the multitude of human and non-human entities that comprise an information system (Tatnall, 2003). The discipline of Information Systems is thus neither merely a technical discipline nor a social one, but one that is truly socio-technical. Systems developers and researchers all face the problem of how to handle the many complexities due to interconnected combinations of people along with computers, peripherals, procedures, operating systems, programming languages, software, broadband connections, switching technology, data, databases and many other inanimate objects. They need to consider how all these elements relate to humans and human organisations, and how humans relate to them (Longenecker, Feinstein, Couger, Davis & Gorgone, 1994; Tatnall, 2009a).

ADOPTION OF WEB TECHNOLOGY: INNOVATION

Just because a new Web technology exists it cannot automatically be assumed that organisations or individuals will want to adopt or to use it. A Web technology will only be adopted if potential users make a decision to do so and the adoption of a technological innovation, such as a Web technology, occurs for a variety of different reasons. Thus the first step in researching the use of a new Web technology by an organisation (or an individual) is to investigate why it was adopted, and so consider the Web technology as a technological innovation. This can be done by examining the adoption of the new Web technology through the lens of innovation theory.

It is important at this stage to distinguish between invention and innovation. Invention refers to the construction of new artefacts or the discovery of new ideas, while innovation involves making use of these artefacts or ideas in commercial or organisational practice (Maguire, Kazlauskas & Weir, 1994). Invention does not necessarily invoke innovation and it does not follow that invention is necessary and sufficient for innovation to occur (Tatnall, 2009b). Clearly the Web technology can be seen as an invention, but the point here is that it will not be used unless it is adopted, and that means looking at it also as a technological innovation. Of course, the application of innovation theory to the adoption of a new Web technology assumes that the potential adopter has some choice in deciding whether or not to make the adoption. In the case of an organisation or individual considering the adoption and use of a Web technology, however, it is difficult to see any reason why they would not have a large measure of choice in this adoption decision. This makes the application of adoption theory quite appropriate when considering the use of Web technology.

A number of approaches exist to modelling how technological innovation takes place, including the Theory of Reasoned Action (Ajzen & Fishbein, 1980), the Theory of Planned Behavior (Ajzen, 1991), the Technology Acceptance Model (Davis, 1986), Diffusion of Innovations (Rogers, 1995; Rogers, 2003) and Innovation Translation (Callon, 1986b; Latour, 1996). In particular, both the Diffusion of Innovations and the Technology Acceptance Model (TAM) are very well known and widely used approaches to theorising technological innovation.

RESEARCHING WEB TECHNOLOGY AND ITS APPLICATIONS

This multi-volume book series contains a large number of research articles on a variety of topics relating to Web technologies, and in this section I will look at how research in Web technology can be categorised (Tatnall, 2009b) and how it is being undertaken. While some of articles on Web technology are fairly descriptive, perhaps examining a commercial product in some depth, others involve detailed analytical research. It appears to me that most of the articles outlining research on Web technology could be classified into three main areas which could, of course, be further subdivided:

- **Web technology:** research on the technical design of computer hardware and software for Web applications.
- **Web implementation:** research issues involved in the implementation of Web sites in specific organisations.
- **Web applications:** research into the many uses of the Web, and the social and political consequences of this use.

Web technology itself has been researched by many scholars, especially those involved in the design and implementation of Web-based systems. This is a wide field and offers many possibilities for fairly technical research articles dealing with various aspects of these systems. Commercial Web technology products and vendors each have an important role to play and their investigation and evaluation provides a profitable avenue of research. Quality issues and standards as well as measurement of effectiveness could also be validly considered. Another important consideration here is whether certain implementation factors are more likely to lead to successful *adoption* of Web technology than others. I will take this point further shortly.

As well as the technology itself, there needs to be some consideration of issues involved in the organisation implementing its Web-based application. Whether the Web technology is based on a commercial product (such as Front Page) or if it is programmed from scratch (in a programming language such as Java or Visual Basic) is itself an important implementation issue. Articles dealing with implementation issues often involve a case study of the organisation implementing the Web-based application and discuss the goals and intentions of using this: how the technology was chosen, the implementation approach used and the problems incurred during the implementation. Not all implementation issues, of course, are technical ones as implementations all involve people.

No doubt the largest area, however, consists of articles that investigate Web-based systems uses and applications, of which there are many. A major user of Web technology around the world is governments and the public sector and most government departments now have their own Web sites. Social and community-based Web sites are also common. At the personal level, research is often conducted into topics including Weblogs, widgets and MP3 players. Medical, health and bio-informatics Web sites form another significant group of applications as do the business and industrial sectors. Much research investigates organisational and management issues regarding Web technology use, human resources and enterprise information portals, Web sites for small to medium enterprises and more specific topics including shopping, the automotive industry and wine industry Web sites. The economics of setting up and using these Web sites is also discussed, as are issues of strategic planning, user acceptance, security and the law. Applications in areas such as business intelligence, artificial intelligence, semantic portals, intelligent agents and mobile technology could also be included here.

The approach used in Web-based systems research depends, of course, on the type of research being undertaken and will most likely differ depending on whether this is related to Web technology itself, implementation or applications. Should a purely descriptive article be considered as research? It is not the place of this chapter to discuss this, but the sort of article I will discuss involves at least some degree of analysis. Articles considering specific Web technology products and vendors will most likely look at some form of analysis of the benefits of this feature or that design approach and may be quite general in nature. As mentioned previously though, apart from articles discussing Web technology itself, most research will in some way relate to the use of this Web technology by some particular organisation and so will probably involve some form of case study.

One research approach that attempts to take proper account of both the social and technical aspects of Web-based information systems is that of Soft Systems Methodology (SSM), a variant on action research developed by Peter Checkland and his colleagues (Checkland & Scholes, 1991) from Lancaster University. SSM attempts to give due recognition to both the human and technological aspects of a system and acknowledges both human and non-human aspects of these systems, which it considers as entirely separate types of entity.

Another research approach is actor-network theory (ANT) that also considers both social and technical aspects of an information system. ANT, however, considers that it is not possible to distinguish between these two types of entities and so attempts to consider and handle both human and non-human entities in the same way.

Actor-network theory proposes that everything we do involves hybrid entities (Latour 1993) containing both human and non-human elements. ANT was developed to analyse situations where separation of these elements is difficult (Callon 1999; Tatnall and Gilding 1999). One could question, for instance, which parts of an information system are just inanimate objects and which are the result of human interactions. If we consider a Web portal, for example, it is difficult to differentiate its technical aspects from the influence exerted by the socio-cultural background of the development team (Cusumano & Selby, 1997; Sahay, 1997). What seems, on the surface, to be social is partly technical, and what may appear to be only technical is partly social.

ANT handles this difficulty in determining the social-technical divide by refusing to allow the possibility that either purely technical or purely social relations can exist. It instead offers the notion of heterogeneity to describe situations such as the development of a website or other web-based system that involves computer hardware, computer software, communications hardware, communications software, telecommunications authorities, cables, portal hosting sites, Internet service providers, data, human analysts, human programmers, human users and so on. The use of heterogeneous entities that can be partly social and partly technical (Bijker, Hughes & Pinch, 1987) then avoids questions of: 'is it social?' or 'is it technical?' as missing the point, which should be: "is this association stronger or weaker than that one?" (Latour, 1988, p. 27). ANT considers both social and technical determinism to be flawed and proposes instead a socio-technical account (Latour, 1986; Law & Callon, 1988) in which neither social nor technical positions are privileged.

"ANT was developed to analyse situations in which it is difficult to separate humans and non-humans, and in which the actors have variable forms and competencies." (Callon, 1999, p:183)

In order to address the need to treat both human and non-human actors fairly and in the same way, ANT was designed upon three fundamental principles (Callon, 1986b):

- **Agnosticism:** analytical impartiality is demanded towards all the actors involved in the project under consideration, regardless of whether they are human or non-human.
- **Generalised symmetry:** explains the conflicting viewpoints of different actors in the same terms by use of an abstract and neutral vocabulary that works the same way for human and non-human actors. Neither the social nor the technical elements in these 'heterogeneous networks' (Law, 1987) are then given any special explanatory status.
- **Free association:** requires the abandonment of all distinctions between the technological and the social (Callon, 1986b; Singleton & Michael, 1993).

Actor-network theory thus attempts impartiality towards all actors in consideration, whether human or non-human, and makes no distinction in approach between them. Callon (1986b, p. 200) puts it this way: "The rule which we must respect is not to change registers when we move from the technical to the social aspects of the problem studied." Callon (1987) further proposes that entities gain strength by gathering a 'mass of silent others' into a network to give them greater strength and credibility. This network then becomes durable partly due to the durability of the bonds that hold it together.

In ANT, an actor is any human or non-human entity that is able to make its presence *individually felt* by the other actors (Law, 1987). It is made up *only* of its interactions with these other actors (de Vries, 1995), and Law (1992) notes that an actor thus consists of an association of heterogeneous elements constituting a network. It should not be considered as a 'point object' but rather as an association of heterogeneous elements themselves constituting a network. Each actor can thus also be considered to constitute a simplified network (Law, 1992). In this sense, an actor can in many ways also be considered as a black-box, and when the lid of the box is opened it will be seen to constitute a whole network of other, perhaps complex, associations (Callon, 1986a). In many cases, details of what constitutes an actor – details of its network – are a complication we can avoid having to deal with all the time. We can usually consider this entity just as an actor, but when doing this it must be remembered that behind each actor there hide other actors that it has, more of less effectively, drawn together (Callon, 1987).

After development, as technological innovations are often not adopted in their entirety or in exactly the form that their proponents suggested, ANT makes use of a theory of Innovation Translation (Latour, 1986; Law & Callon, 1988; Latour, 1996) which suggests that before adoption, an innovation is first 'translated into a form which is more appropriate for use by the potential adopter. Callon et al. (1983) propose that translation involves all the strategies through which an actor identifies other actors and reorganises them in its own way.

The main advice on method suggested by the proponents of actor-network theory is to "follow the actors" (Latour, 1996) and let them set the framework and limits of the study themselves. The process followed in an ANT analysis is thus far from linear, and not just simply a matter of collecting data and then analysing it.

I will argue that two things make actor-network theory very appropriate for researching and discussing web-based systems and for framing all but the type of research that only describes the technology itself. First is its treatment of both human and non-human actors and of the interactions between them. There is no doubt, in my view, that both human and non-human actors including the hardware, software and communications technologies themselves, jointly effect the outcome of implementing any web-based system. To consider one and ignore the other would give a very one sided view of what is going on. For example, suppose that a particular technology is too expensive or too difficult to use. There is then little likelihood of it being adopted and used properly. On the other hand suppose that this technology does not fit with the way that a particular organisation does its business. This is not necessarily due to the nature of the technology alone any more than it is due alone to the human factors of the way that business is done. It is more likely due to the interaction of each of these factors. In another situation, what one person or organisation considers the perfect technological solution will not necessarily suit another. The reasons it might not suit them could be complex and have more to do with cultural or social issues than technical issues. A consideration of both human and technological aspects of these systems then is essential.

Another advantage of using ANT is in its treatment of the adoption of innovations. Most other approaches to innovation adoption consider only whether some technology is adopted or not and do not give put much store on partial adoption. When investigating this area it is often the case that one person or company will adopt certain features of Web technology and not others that it could have been expected to adopt. There will then often be another similar company that adopts other different features of the same technology. One must then question the reason for this, and actor-network theory's approach using Innovation Translation has the ability, I would suggest, to explain this well. ANT suggests that before adoption, a technological innovation must first be 'translated' into a form appropriate for adoption by the organisation concerned. It so offers the means for explaining partial adoptions. In my own research I have found actor-network theory a very useful research methodology in working with socio-technical systems involving Web technology (Tatnall, 2009c).

ISSUES AND TRENDS: CONCLUSION

It is always dangerous to attempt any predictions into the future of technology. Thomas Watson (Senior), then President of IBM, is alleged to have stated in 1943: "I think there is a world market for maybe five computers". Whether Watson made this statement of not, and there is little evidence that he actually did, it highlights the danger in making future predictions related to information and communications technologies. I am, however, I think fairly safe in saying that for the future of the Web three things seem fairly clear.

1. The Web will continue to grow in size as move users (particularly in developing countries) move to adopt web technologies and more information is put onto the Internet. No doubt this will put considerable pressure on the infrastructure, but with new technologies this problem should be overcome.
2. The speed of access to the Web will continue to increase as governments around the world put in new higher speed broadband infrastructure. This will mean that websites can contain even more multi-media material.
3. More people will access the Web with the aid of mobile computing technologies, meaning that the Web will become more accessible everywhere.

Questions that do not have a clear answer are whether access to most websites will continue to be free of cost and whether governments around the world will keep their hands off the Web or want to exercise a greater degree of control as some governments now do. Given that the Web has been around for only about 15 years it will be interesting to see what a book about the Web in 15 years time will say – perhaps there will then be no need for such a book as the Web will have become so well know that there will be no need for one.

ENDNOTE

1 Conseil Eroeen pour la Recherche Nucleaire (CERN) – an international scientific organisation based in Geneva, Switzerland.

About the Editor

Arthur Tatnall (BSc, BEd, DipCompSc, MA, PhD, FACS) is an associate professor in the Graduate School of Business at Victoria University in Melbourne (Australia). He holds bachelor's degrees in science and education, a graduate diploma in computer science, and a research MA in which he explored the origins of business computing education in Australian universities. His PhD involved a study in curriculum innovation in which he investigated the manner in which Visual Basic entered the curriculum of an Australian university. He is a member of three IFIP working groups (WG3.4, WG3.7 and WK9.7) and is also a fellow of the Australian Computer Society. His research interests include technological innovation, information technology in educational management, information systems curriculum, project management, electronic commerce, and Web portals. He has written several books relating to information systems and has published numerous book chapters, journal articles and conference papers. He recently edited *Encyclopedia of Portal Technology and Applications* for IGI Global.

Section I
Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of Web technologies. Chapters found within these pages provide an excellent framework in which to position Web technologies within the field of information science and technology. Individual contributions provide overviews of the mobile Web, semantic Web, and Web 2.0, while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of Web technologies.

Chapter 1.1

ICT and Interculture Opportunities Offered by the Web

Laura Corazza
Università di Bologna, Italy

BACKGROUND

In Italy, as in other European countries such as Germany and France, the words "multicultural" and "intercultural" have distinct meanings[1]. In some ways the passage the one from the other indicates the evolution of a concept that, when examined in detail, forces us to re-examine educational political, and cultural choices in a society.

"In Italy, especially in the field of pedagogy, the term multicultural indicates a situation where cultures co-exist side by side but as yet, have not found a means of comparison and relating to each other . <…>. The term *intercultural*, which originated in France and then spread to other European countries, on another hand, describes a situation of interaction between different cultures, often describing a prospect, a possible point of arrival or an objective to strive for; a situation in which the people of different cultures begin to open up to reciprocal relationships, thereby bringing about the possibility of integration, characterised by a political and cultural pluralism which aims at reciprocal respect and appreciation between the respective cultures"[2]. With Multiculturalism, people accept to live with those from other cultures with tolerance but without promoting forms of exchange and democratic co-existence. The form of social organization that derives from this is that of the "melting pot" which encourages the development of ghettos or "Little Italy" and "China towns". However the Intercultural approach is reciprocal. It is for those who accept and listen, those who are tolerant, those who are not afraid of "contamination" but constantly seek to mediate between different points of view and backgrounds.

Among various other factors, it is globalization, encouraged by new communication and information technologies, that has contributed to the transformation of contemporary world-wide society into a multicultural society. These technologies have made it possible to communicate easily and at low cost with every corner of the planet. We can observe events which are taking place all over the world and take part in collective cultural processes. The Internet is made up of interconnected nodes without a centre. It encourages the growth of new trans-national communities on various levels, ranging from the political and professional to the scientific. It produced some elements of standardization, such as the use of a single language, English and has lead to uncommon social contacts on a worldwide level. At the same time however, these new communication technologies can also be viewed as a further cause of the divide between those who can access information and participate in the creation of knowledge and those who cannot.

FOCUS

The concept of freedom of access to information is an integral part of the philosophy and history of the Internet. It is also guaranteed by the characteristics of computer mediated communication and tools such as e-mail, forums, mailing lists, blogs and portals. CMC has changed the concept of communication itself. Leaving behind the one-way logic of communicator- receiver (typical of traditional mass media) the situation has become one where individuals are nodes in a network, part of an interconnected environment. The individual has the active role of social participant in communication rather than being a passive consumer (as in the case of television).

In addition to this, there are a number of new opportunities available for the user. It is now possible to influence the information circuit significantly. People can provide information as well as obtain it, they can teach as well as learn and participate not only as an individual, but as part of a group. From the moment a person becomes aware of this new communicative reality and has the possibility of taking part in it, he or she possesses new rights and also responsibilities. The rights include the opportunity to access the Web and its contents independently of limits (economic, time, and movement) and diversity (cultural, social, cognitive, or physical). To this we can add the right to learning. This must take into consideration, not only the acquisition of technical and procedural knowledge but also cognitive, emotive and social competences which are needed in order to participate with full awareness in a form of communication which is also building knowledge. There also the ever present problem of standardized positions, so the individual must be aware of personal expectations and needs, and adopt a critical, constructive attitude and be able to question, make hypotheses, choices and checks. Moreover, it is necessary to do this in a social setting which requires emotional control and an ability to collaborate, mediate and negotiate.

The communicative environment is that of the Web where the passage between the exchange of information and the building of knowledge is potentially fast, thanks to the network that allows for an exchange rather than a one-way flow of information. This environment is one of democratic co-existence based on mutual respect. It appreciates individuality and cultural and social diversity. At the same time the right to access is also accompanied by certain responsibilities towards others. Anyone who takes part in this communicative process becomes an adherent of the philosophy of Internet. As a direct consequence of its genesis and evolution, it appears to be more closely associated with the technology of freedom rather than that of control, and with democratic relationships rather than ideological imperialism.

There are various types of free information on the web today. They can be placed into two categories: new forms of news agencies and new forms of publishing. Both fit into to the intercultural and democratic view which requires free information, originating “from below” that is, from all the links in the network, combined with fast transmission speeds and a high level of diffusion. Examples of the first category are blogs and more organised agencies such as Misna, an international press agency run by congregational missionaries in Africa, Asia, Latin America and Oceania. Though possessing few resources it can boast many successes and has earned “recognition after only a brief period of activity including the award of the ‘St Vincent 2002’ journalism prize”[3].

The archives of scientific literature (papers, journal articles, addresses made at conferences) are another important example of freely available information on the Net. Offered in an electronic format at no cost, by the very universities that finance the research and believe in the principle of free access to information, they are potentially useful to everyone from college students in America to the doctor in a hospital in Tanzania

Thus we can state the Internet’s contribution to interculturalism has manifested itself in three ways: the creation of a cyber-culture; in a new concept of knowledge; and in the participation “from below” in the building of learning:

Internet as a place of communicative interaction and universal culture.

For Lévy, what is interesting about cyberculture is the coming together of all differences and heterogeneity. He believes in the ability of cyberspace to bring out the best of human intelligence in every person through communicative relationships which create a collective intelligence and a cyber-culture. In this sense we can assert that cyber-culture is both a transculture and an inteculture, since it is universal without being oppressively uniform.

If we take cyberspace to be the *location*, then communication is the *means* that permits the creation of this collective intelligence and cyber-culture. Computer users can communicate with each other in a novel way on the Internet since they can be more than mere passive users and isolated consumers like today’s television viewers. Communication is not limited to “one to one” exchange. In cyber culture it is reciprocal, interactive and communitarian. Moreover it is universal as anyone can be an active communicator. The expansion of interconnections displays the fact that there is one general humanity. This is what Levy means by “universal”: the idea of universality in the Enlightenment sense of the word, where our goal is the unity of human kind and the affirmation of universal principles such as the rights of Man. All human beings can come into reciprocal contact virtually and become conscious collectively of their existence. The more we add links, the more diverse and heterogenic material is circulated on the net. Humanity is becoming aware of itself (universality) but this awareness has no one meaning. It does not pass through one central point and is not bound by any set of laws unlike science where, for example, universal gravitation is the same everywhere. What is interesting in cyber-culture is the bringing together of all differences and heterogeneity

Internet as a location for new knowledge which is open, complex, multidisciplined, individual, and collective at the same time.

Morin (2000) has highlighted the problem of the inadequacy of knowledge (which is *divided* by the boundaries between disciplines while the reality of the world is increasingly global and interconnected) and the challenge of complexity. Complexity is a method and a form of knowledge which requires a dialogical approach. Gregory Bateson also spent his life demonstrating the interdependence between elements and the interconnections between different worlds and disciplines. He theorises about the ecology of ideas, an ecosystem in which there is a plurality of levels of application of ideas, using a systematic approach which, from the point of view of learning means giving importance to contexts, relationships and functions.

So the new idea of knowledge, does not only refer to concepts that are to be *transmitted* but, above all, to the itineraries and the network of individual and collective experiences which are in a state of perpetual change.

This is the challenge that the individual can take up, not withstanding the risks of cognitive standardisation on one hand, and fragmentation or individualism on the other. Morin's "tête bien faite" requires the full use of intelligence in the organisation of ideas, in the search for links, routes and new itineraries, knowing full well that it is not possible to attain totality but that we must put into *practice* collective and individual cognitive *practices* at the same time because they exploit the power of connectivity. "If a document is put on the World Wide Web you are doing two things at the same time: firstly, you are increasing the amount of information that is available, but secondly, you are doing another thing with the links between your document and the others: you offer the surfer who finds your document your point of view. So you are not merely offering information but a point of view in a collection of information. The World Wide Web is not only an enormous mass of information, it is the expression of thousands of different points of view. It should be viewed from this aspect" (Levy, 1995). There is space for every diversity and every point of view on the Web which doesn't have to become individualism, if you allow yourself to become enchanted by hypertextual logic, by the links and maps and if you allow yourself to feel part of a whole, a collective intelligence and a universal culture.

Internet as a place for forming an opinion, expressing a critical judgement, and participating in the building of knowledge.

A surprising example of the impact of the Internet on the power of the individual and thus of the group, is the increase in public access to health information. This is not just another step in the spread of knowledge, but a political change which introduces a new balance of power. More and more patients arrive at their doctor's with information they have found on the Web. It may be incomplete or taken from dubious sites, but they begin their treatment in a more knowledgeable and participative way. Even though there are limits and the information is certainly not enough to provide specialist knowledge, it is enough to modify the power/knowledge rapport in the doctor/patient relationship.

The potential for forming opinions, and thereby expressing judgements and making demands aided by the Web, is becoming more apparent in the political development of citizens. People can participate in public debates as they once did in the classical agora. They can inform themselves and take up positions through blogs, messaging systems and online journalism.

If we say that technology is not neutral and the choice of technology produces profound effects, the most evident effect of the Internet is the transition from vertical to horizontal communication. The first has an undeniably authoritarian nature, even if the intentions of those using it are democratic, since it requires a silent, passive viewing. The second however, permits active participation, and while this alone is not enough to confer unquestionably democratic credentials, it certainly transforms the quality of communication. In general, the passage from one-way communication to interactivity does not automatically guarantee a growth in democracy. On the contrary it can increase the use of extorted consensus to legitimise solutions taken without the effective participation of citizens.

The key question is thus the following: Can the Internet be used to manipulate consensus? Is there a social use of new technologies? Up to now citizens have been subjected exclusively to vertical information offered by television, which creates passivity in viewer. The condition of citizens using the web, benefiting from horizontal communication which blurs the distinction between producers and consumers and the supremacy of the former over the later, is totally different. Everyone becomes a supplier of information, and as such, an active player in communication. The most marginalized of Internet users can have word power equal to that of a government, especially when the news they wish to communicate is information that others want to suppress at any cost. Censorship becomes much more difficult, but with one condition: that there is a real mass internet information literacy program and a true universal service. Without this there is the risk that an information apartheid emerges. Moreover, there is also the danger of *hyper-information,* where citizens are unable to pick out the important information and check its validity due the potentially unlimited quantity of information available. It is for this reason too that the role of education in permitting a social use of new technologies is increasing. It has an important part to play in training active, knowledgeable citizens, to guarentee an adequate command of the tools necessary for developing the competences required by society.

According to Rifkin, cultural production is the first level where the economic life of a country is played out. In consequence of this, there is a strong move to control such production in the direction of a standardised predetermined models (Rifkin, 2000).

But if it is true that the Internet is disliked by governments because it cannot be censored or controlled easily, it can also become a tool in the democratic education of citizens, if the move towards liberty prevails over that towards standardisation. A conscious citizen is a person who participates in the building of a free, universal society which is constantly developing and changing. The process of building knowledge that can come about through the use of the network of ideas and information available on the Internet produces social progress. This is what Dewey calls "social efficiency": everything that makes an experience valid for the community, as well as oneself; everything that makes it communicable and useful in the demolition of social barriers. The same efficiency that he considers to be the final aim of education in a democratic society.

CURRENT LIMITS AND FUTURE DEVELOPMENTS

Technology of Freedom or Technology of Control?

Whether we consider technology to be neutral, or something that can structure the user's activities, we cannot avoid reflecting on the responsibilities of those who use it and the need for user-education. Whilst there is a great potential for helping humanity, we face a number of new questions. A critical analysis can reveal both positive and negative aspects, opportunities and risks, and a possible direction to take in order to achieve a democratic use for the civic education of the citizen. The key question is that posed by Stefano Rodotà: Are we using the technology of freedom or the technology of control? Can the use of technology be free from rules? Is it necessary to reflect on which direction we should be striving for?

We need to free ourselves from some vices of form and clichés that linger, such as technological arrogance (and the idea that technology does not need rules), the optimism of the market (which in reality favours economic interests over social equality) and the political-ideological simplification which sees technology as a cure for all evils (in reality technology is not neutral but requires careful use)

The Digital Divide

Regarding access to the new communication technologies and the internet in particular, there are no equal opportunities between the technologically advanced rich countries and countries which are technologically behind. In a message of 2002, the secretary general of the United Nations Kofi Annan underlined the importance of communication technologies and exhorted poor countries on the African continent to unite to create a digital revolution which had become indispensable. In collaboration with the ITU International telecommunications union the UN organised the first World Summit on the Information Society, WSIS with the aim of building a common vision of the information society and adopt a plan of action to bring it about[4].

The first principle of the Geneva declaration states:

We, the representatives of the peoples of the world, assembled in Geneva from 10-12 December 2003 for the first phase of the World Summit on the Information Society, declare our common desire and commitment to build a people-centred, inclusive and development-oriented Information Society, where everyone can create, access, utilize and share information and knowledge, enabling individuals, communities and peoples to achieve their full potential in promoting their sustainable development and improving their quality of life, premised on the purposes and principles of the Charter of the United Nations and respecting fully and upholding the Universal Declaration of Human Rights.

It is not enough to be connected to resolve the fundamental problems of underdevelopment and to ensure that the Information Society becomes a vehicle for democracy, justice, equality and respect for individuals and their personal and social development. Beyond the mere physical availability of a computer, other factors such as economic/social resources and levels of literacy, influence the successful use technology. It is the development of the necessary competences and a fruitful, informed use of the internet that is the challenge for the current Information Society and lifelong learning in particular.

CONCLUSION

In conclusion Internet is a wonderful opportunity (comparable with the impact on culture of the invention of the printing press) not only when we consider the technical changes in the exchange of information and the spread of knowledge, but also for the political, social and educational implications. In substance we have to start to conceive and use new democratic environments for the production of culture, new forms of diffusion which offer efficient tools for communication between individuals, disciplines and political and social points of view. To use a more traditional pedagogical language, what emerges from the analysis of the spontaneous (and in some cases experimental) use of the internet is the necessity to use the great potential for communicative and didactic renewal which is beginning to manifest itself, in order to produce a culture that overcomes individualism and is oriented towards forms of collaboration which widen the opportunities for democratic participation in the information/knowledge process. By moving in this direction perhaps we can cement the relationships between individuals, groups, states, and political organisations providing a glimpse of the added value of cooperation, reciprocity, peace, and thus interculture.

KEY TERMS

Cyberculture: For Lévy, what is interesting about cyberculture is the coming together all differences and heterogeneity. He believes in the ability of cyberspace to bring out the best of human intelligence in every person through communicative relationships which create a collective intelligence and a cyberculture. In this sense we can assert that cyberculture is both a trans-culture and an interculture, since it is universal without being oppressively uniform.

Democratic Education: Morin has highlighted the problem of the inadequacy of knowledge (which is *divided* by the boundaries between disciplines while the reality of the world is increasingly global and interconnected) and the challenge of complexity. Complexity is a method and a form of knowledge which requires a dialogical approach. Gregory Bateson also spent his life demonstrating the interdependence between elements and the interconnections between different worlds and disciplines. So the new idea of knowledge, does not only refer to concepts that are to be *transmitted* but, above all, to the itineraries and the network of individual and collective experiences which are in a state of perpetual change. The process of building knowledge that can come about through the use of the network of ideas and information available on the internet produces social progress. This is what Dewey calls "social efficiency": everything that makes an experience valid for the community, as well as oneself; everything that makes it communicable and useful in the demolition of social barriers. The same efficiency that he considers to be the final aim of education in a democratic society.

Democratic Information: The concept of freedom of access to information is an integral part of the philosophy and history of the internet. It is also guaranteed by the characteristics of computer mediated communication and tools such as e-mail, forums, mailing lists, blogs and portals. CMC has changed the concept of communication itself. Leaving behind the one-way logic of communicator-receiver (typical of traditional mass media) the situation has become one where individuals are nodes in a network, part of an interconnected environment. The individual has the active role of social participant in communication rather than being a passive consumer (as in the case of television).

Information Society: It is now possible to influence the information circuit significantly. People can provide information as well as obtain it, they can teach as well as learn and participate not only as an individual but as part of a group. From the moment a person becomes aware of this new communicative reality and has the possibility of taking part in it, he or she possesses new rights and also responsibilities. The rights include the opportunity to access the web and its contents independently of limits (economic, time, and movement) and diversity (cultural, social, cognitive or physical). To this we can add the right to learning. This must take into consideration, not only the acquisition of technical and procedural knowledge but also cognitive, emotive and social competences which are needed in order to participate with full awareness in a form of communication which is also building knowledge.

Intercultural Education: In Italy, as in other European countries such as Germany and France, the words multicultural and intercultural have distinct meanings. In Italy, especially in the field of pedagogy, the term multicultural indicates a situation where cultures co-exist side by side but as yet, have not found a means of comparison and relating to each other. The term *intercultural*, which originated in France and then spread to other European countries, on the other hand, describes a situation of interaction between different cultures, often describing a prospect, a possible point of arrival or an objective to strive for; a situation in which the people of different cultures begin to open up to reciprocal relationships, thereby bringing about the possibility of integration, characterised by a political and cultural pluralism which aims at reciprocal respect and appreciation between the respective cultures.

ENDNOTES

[1] In North American and the majority of English speaking culture however the term *multicultural* is most widely used (especially in education). This can be observed when consulting ERIC, the bibliography data base of the U.S. Department of Education which specializes in topics relating to pedagogy and didactics and representative of North American scientific literature. In its thesaurus *intercultural education* is only considered as a synonym for *multicultural education*. The only exception is *intercultural communication*.

WEB SITES

The Open Archives Initiative develops and promotes interoperability standards that aim to facilitate the efficient dissemination of content. The Open Archives Initiative has its roots in an effort to enhance access to e-print archives as a means of increasing the availability of scholarly communication. Continued support of this work remains a cornerstone of the Open Archives program. The fundamental technological framework and standards that are developing to support this work are, however, independent of the both the type of content offered and the economic mechanisms surrounding that content, and promise to have much broader relevance in opening up access to a range of digital materials. As a result, the Open Archives Initiative is currently an organization and an effort explicitly in transition, and is committed to exploring and enabling this new and broader range of applications. As we gain greater knowledge of the scope of applicability of the underlying technology and standards being developed, and begin to understand the structure and culture of the various adopter communities, we expect that we will have to make continued evolutionary changes to both the mission and organization of the Open Archives Initiative.

Public Library of Science,http://www.plos.org/

PLoS, a nonprofit organization of scientists and physicians committed to making the world's scientific and medical literature a freely available public resource. As of 2006 it publishes *PLoS Biology*, *PLoS Medicine*, *PLoS Computational Biology*, *PLoS Genetics* and *PLoS Pathogens*. PLoS ONE is a new journal to be launched soon.

Our goals are (1) to open the doors to the world's library of scientific knowledge by giving any scientist, physician, patient, or student—anywhere in the world—unlimited access to the latest scientific research. (2) Facilitate research, informed medical practice, and education by making it possible to freely search the full text of every published article to locate specific ideas, methods experimental results, and observations. (3) Enable scientists, librarians, publishers, and entrepreneurs to develop innovative ways to explore and use the world's treasury of scientific ideas and discoveries.

Chapter 1.2
Mobile Social Web:
Opportunities and Drawbacks

Thorsten Caus
Georg August University of Göttingen, Germany

Stefan Christmann
Georg August University of Göttingen, Germany

Svenja Hagenhoff
Georg August University of Göttingen, Germany

ABSTRACT

As mobile Internet usage continues to grow, the phenomenon of accessing online communities through mobile devices draws researchers' attention. Statistics show that close to 60 percent of all mobile Internet traffic worldwide is related to the use of mobile social networks. In this chapter, the mobile social Web is defined, categories of mobile communities explained, and success factors and drawbacks discussed from the technical, social, and economic perspectives. Challenges, including low transmission rates, changes in usage patterns, search for new revenue sources, as well as the need for development of original mobile Web content and applications are addressed. The technical requirements for the mobile use of online communities are identified. The chapter closes with a summary of potential economic and social prospects of the emerging mobile social Web.

DOI: 10.4018/978-1-60566-368-5.ch002

INTRODUCTION

Until recently, the Internet was a domain restricted to stationary computers, but nowadays it can also be accessed through mobile devices equipped with web browsing capabilities. Now it is not only possible to surf the web using wireless access and mobile devices, but there is also a growing number of mobile Internet applications and services. Increasingly, mobile social networking applications have been made available to a large number of mobile phone users.

Internet users have accepted online communities and internalized the concept of the Social Web also referred to as Web 2.0 (Koesch, Magdanz, & Stadler, 2007). Private as well as business users have become familiar with various online communities (Patrzek, 2007; von Tetzchner, 2008). On the one hand, mobile social networks are becoming more widespread because of the increasing dissemination of new wireless communication technologies (Heng, 2006, p. 5). On the other hand, a large number of devices are designed to implement new communications technologies, for example, the Universal Mobile Telecommunications System (UMTS) in Europe (Heng, 2006, p. 1).

Studies conducted by Opera Software, an Internet software and services company, demonstrate that 40 percent of all mobile Internet traffic worldwide is related to the use of online communities. In some countries the share is as high as 60 percent: for example, in the United States, South Africa, and Indonesia (von Tetzchner, 2008). Research into the various ways of using the Social Web in a mobile context is now of paramount importance. In this chapter, *mobile social web* is defined, categories of mobile online communities and their success factors explained, and selected opportunities and drawbacks of the mobile online communities discussed from a technical, social, and economic perspectives.

BACKGROUND

The Social Web can be viewed as a concept and a platform that utilizes social software (e.g., forums, wikis, blogs, etc.) to fulfill or support some of the important human needs, such as: self-realization, acceptance, social connectedness, and safety (Maslow, 1943, p. 372-383). The purpose of the Social Web is to support human communication and facilitate social contact. The Social Web encompasses numerous Internet applications, such as social networking sites, massively multiplayer online role-playing games, photo and video sharing, online stores and auction houses, virtual worlds, and wiki collaborations. The most popular and widespread actualizations are online communities (e.g., MySpace, Facebook, StudiVZ or XING). The term "Social Web" is often used in everyday language as well as in scholarly literature as a synonym for "virtual" and "online communities" (Hummel, 2005, p. 5), although these terms do not differ greatly (Fremuth & Tasch, 2002, pp. 5-6).

In the past years many academic disciplines have dealt with the Social Web. Various attempts to provide a definition have resulted in three different approaches: technical, social, and economic. The technical approach focuses on the Internet as a medium or platform for a community. The sociological point of view stresses the forming and functioning of communities, whereas the economic perspective examines potential gains and intended profits (Hummel, 2005, p. 8-11).

These three perspectives have led to a variety of definitions of online communities with differing points of emphasis. A detailed overview of common definitions is given by Fremuth and Tasch (2002), Hummel (2005) and Markus (2002). In identifying an *online community* one perspective emphasizes that it is formed by a group of people, while another stresses its web platform. The definition used in this chapter combines both approaches, for an *online community* is seen as a social group that interacts through a web platform over an extended period of time.

An online community can be characterized by four elements (Gebert & von Rosenstiel, 1992, p. 122-123; Hamman, 2000, p. 225):

- group of people with shared objectives (e.g., interests, goals)
- interaction over an extended period of time
- closeness due to bonds and relationships
- shared space for interactions governed by certain rules (for example, role definitions).

Without shared objectives there would be no interaction and relationship and, subsequently, no community at all (Markus, 2002, p. 36). Interactions within the community are seen as topic-oriented communication as well as the execution of actions (Kim, 2000, p. 5). Both can take place independently of time and location (Winkler & Mandl, 2004, p. 14). The process of founding and maintaining such online communities usually takes place on the Internet (Eigner & Nausner, 2003, p. 58). The second defining characteristic is the web platform, which can be seen as an Internet communication system which acts as an intermediary. It enables and facilitates meetings, the maintenance of the community, and its interaction with other people (Reichwald, Fremuth, & Ney, 2002, p. 8).

There are different ways of categorizing online communities (Brunold, Merz, & Wagner, 2000, p. 30-37; Fremuth & Tasch, 2002, p. 21; Hummel, 2005, p. 46). A reasonable approach is to categorize them according to similarities, for they play a major role in online communities. Therefore, an online community can be geographic (bound to an area), demographic (classification according to nationality, age, gender), or based on shared interests or activities (Kim, 2000, p. 5).

Online communities can be viewed as social systems. Relationships and interactions can only develop once a web platform has been established, which makes it difficult to start a community (Leitner, 2003, p. 36). The network-effect character of online communities shows this very clearly. There will only be accelerated growth once a critical amount of relationships and interactions between users has been achieved. This is due to the fact that users do not benefit before this point is reached (Reichwald, Fremuth, & Ney, 2002, p. 8). Even though this development is difficult to predict, an operator is able to influence the development of an online community by making it more attractive (Reichwald, Fremuth, & Ney, 2002, p. 9-10). The success factors that have been identified are listed in Table 1.

THE MOBILE SOCIAL WEB

The mobile use of online communities can be referred to as the *mobile social web*. In this context, *mobility* is understood as the unrestricted transfer of text, voice or data independent of user's physical location (Kurose & Ross, 2005, pp. 536-538). Therefore, mobile online communities are free of interruption caused by the movement of the user from one location to another. The devices employed can be either wireless or wired (Kurose & Ross, 2005, p. 504). Suitable types of devices are mobile phones, smart phones (Michelsen & Schaale, 2002, p. 51) and personal digital assistants, as these can always stay switched on and do not need to be booted. Although mobility does not necessarily require wireless connections to these devices, wireless mobile networks are used most commonly (Gerum, Sjurts, & Stieglitz, 2003, p. 145). European standards, for instance, include the Global System for Mobile Communication (GSM) extensions, Enhanced Data Rates for GSM Evolution (EDGE) standard (Herzig, 2001, p. 399), General Radio Packet Service (GPRS) protocol (Stader, 2001, p. 37), and the 3rd generation Universal Mobile Telecommunications System (UMTS) technology (Kurose & Ross, 2005, pp. 534-535). The mobile social web involves opportunities as well as drawbacks, as will be discussed below.

Opportunities of the Mobile Social Web

The features of mobile communities generally correspond to those of traditional online communities. They are enhanced by a new way of accessing the community-web-platform through mobile, wireless devices. On closer examination,

Table 1. Success factors on online communities (adopted from Koch, Groh, & Hillebrand, 2002; Leitner, 2003)

Users' point of view	Corporations' point of view
• Advantages of usage, for example in the form of problem solving or entertainment • Simple compilation of contributions • Easy technical access, usage and adequate stability • Equality, credibility and trust • Non-commercial orientation	• Personal network and personal characteristics of entrepreneurial team • Product or service idea in business model • Available resources and capabilities • Marketing strategy with viral emphasis • Potential for speedy marketing

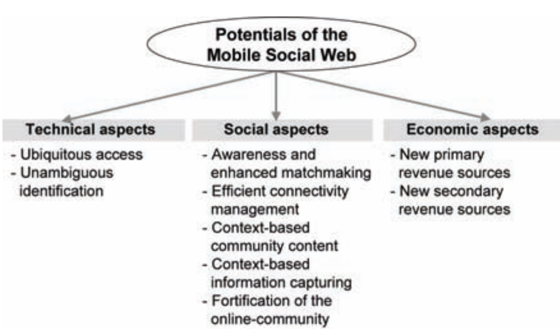
these communities do not only seem to benefit from mobile access, but also from additional potentials resulting from mobility and localization possibilities. Furthermore the question arises, whether this newly opened potential encompasses not only technical and social aspects but economic aspects as well (see Figure 1).

Technical Aspects

Mobile wireless devices facilitate ubiquitous access to online communities (Koch, Groh, & Hillebrand, 2002, p. 2). The user is able to gain access anywhere and any time, while being liberated from the world of stationary Internet and permanently installed devices (Reichwald, Fremuth & Ney, 2002, p. 6). Furthermore, users benefit from being reachable at all times by being armed with mobile wireless devices (Wiedmann, Buckler, & Buxel, 2000, p. 86). Therefore, the users can stay online and be accessible continuously and without interruption. No time is lost: for example, by turning the devices on or logging in. Thus, interaction becomes more spontaneous and expressive.

Mobile wireless devices make it possible to identify the user via his PIN and SIM card, both of which are requirements of mobile communications (Tasch & Brakel, 2004, p. 4). This explicit possibility of identification can be used to identify the user in an online community. The user's mobile device then serves as a membership card or an individual entrance ticket (Reichwald, Fremuth, & Ney, 2002, p. 7). Identifying the user can be automated, making it more reliable. It is also more authentic and results in more confidence within the community (Hummel, 2005, p. 72).

Figure 1. Overview of the mobile social web potentials



Social Aspects

A local context can be defined by identifying a user's current whereabouts (Koch, Groh, & Hillebrand, 2002, p. 3). A user's whereabouts could be presented to other users through geomapping or textually. Furthermore, an awareness service could be employed in addition to existing information services, such as "buddy lists" (Tasch & Brakel, 2004, p. 7). Contacts and friends in the vicinity of the user can be shown on the mobile device. Mobile online communities could thus improve interactions between community members and extend social ties. For example, people with similar interests can get together spontaneously. Contexts can be used to find out about the accessibility of mobile community users (Groh, 2003, p. 9). Depending on the user's current whereabouts a service can provide information about if and how a person may be contacted and the user can decide how to do this. The contact information can simply rely on such area aspects as availability of UMTS. Personal preferences can also be used for this purpose.

Another potential feature is to filter content according to current contexts (Groh, 2003, p. 9). A personal information service can select information about places of interest in the vicinity of the user's current location and report it to the user (context specific presentation of information). Moreover, context specific capturing of content is conceivable (Groh, 2003, p. 8). Metadata (e.g., location data or location names) and information and news services form the basis for this idea. For example, an entry reviewing the quality of food and drinks in a local café could be generated automatically by entering the name of the café or its location.

Personal meetings can be organized more easily as the awareness of a person's location increases, matching the users' interests is extended, and the management of accessibility becomes more efficient. Stronger relationships between persons will typically result when they are geographically close and have personal encounters (Larsen, Urry, & Axhausen, 2006, pp. 12-13). These aspects are not available in stationary online communities because they depend on time and location. Face-to-face communication can lead to an improved quality of relationships because interactions become closer and more intense. All of the above will result in the strengthening of a community (Schneider, 2003, p. 99).

Economic Aspects

Mobile communities allow an opportunity for spontaneous, affective, and meaningful community activities, which may result in closer relationships between community members than in the case of traditional online communities. Data input and output can be accomplished more easily through context specific services (Diekmann et al., 2006). Therefore, community mobile operators assume that users will be more willing to pay for participation in mobile communities than in stationary online communities (Reichwald, Fremuth, & Ney, 2002, p. 12). The following list provides details of primary and secondary revenue sources for mobile operators (Reichwald, Fremuth, & Ney, 2002).

Primary revenue sources arise from operating a mobile online community (Reichwald, Fremuth, & Ney, 2002, p. 11). Three possibilities can be identified:

- *To levy usage fees:* Users pay for the usage of mobile information and interactivity services and for community content. The fees depend on the usage of the services or they are usage-independent (Reichwald et al., 2002, pp. 24-25). Users pay either for the usage of each single service or for using services during a certain period of time. Both approaches have proved unsuccessful in the case of non-mobile online communities (Reichwald et al., 2002, pp. 23-24). It may be expected that the advantages of mobile communities and their improved attractiveness are great enough to generate an increased willingness to pay (Reichwald, Fremuth, & Ney, 2002, p. 12). Moreover, users are generally accustomed to paying for mobile services.
- *Advertising and sponsoring:* Even now, non-mobile online communities allow the generation of advertisements tailored for special target groups by analyzing user profiles. In comparison to mass advertisements, this approach involves less wastefulness (Schubert & Ginsburg, 2000, pp. 51-52). For example, depending on the user's current location, advertisements can be provided. Companies willing to sponsor certain activities are another potential source of revenue (Reichwald et al., 2002, p. 20).
- *Data transmission fees:* Fees for using telecommunication (TC) services have to be paid to the TC companies. The operator of a mobile online community could negotiate a share of the revenues. For this revenue sharing purpose, cooperation between the TC company and the community operator is needed, and accounting models have to be developed.

The users themselves can become the potential generators of possibilities to earn money for the community. Their content contributions can be used for market research as well as ideas about new services and products. Documented behavior, usage patterns, and preferences can be used to filter properties of target groups. The main potential for community operators has to be made up by selling the gathered knowledge as consulting services or by using it for themselves (Reichwald, Fremuth, & Ney 2002, p. 12). Mobile communities can facilitate activities at a higher level of utility and quality, as data are potentially more differentiated and reliable compared to stationary activities.

Drawbacks of the Mobile Social Web

Mobile online communities have drawbacks, as summarized in Figure 2.

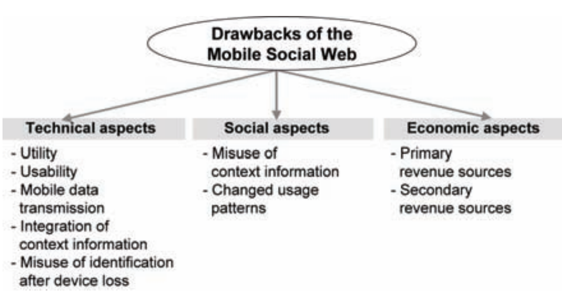
Technical Aspects

The utility of a service is a success factor as well as a challenge. It has to be decided which services should be accessible in a mobile community to make it attractive (Yom, 2002, p. 177). Not only information and interaction services have to be selected, content needs to be chosen, too. Restricted possibilities of data presentation and device handling as well as limited capacities of mobile devices affect the utility.

Other factors influencing usability are data transmission costs, low data transmission rates, device handling problems, and inconvenient data input and output possibilities (Bliemel & Fassott, 2002, p. 14). The fees of mobile network operators are mostly based on data volume. Therefore, a community user will have to pay fees depending on the intensity of his or her usage.

Low data transmission rates are often a problem for mobile device users. Established GSM services, such as Short Message Service (SMS), provide an adequate transmission rate; however, there are only limited possibilities for data presentation. Consequently, it makes more sense to opt for 3rd generation technologies like GPRS and UMTS, especially as the increasing dissemination of these technologies renders this alternative increasingly feasible.

Figure 2. Overview of the drawbacks of the mobile social web



An appropriate localization technology must be integrated in order to realize enhanced mobile services and provide new functionalities of mobile online communities, such as contextual community content, context-oriented information collection, or efficient connectivity management. The localization of end devices connected to cellular networks via their radio cell is currently still expensive. However, free and precise localization using Global Positioning System (GPS) is not yet feasible, as the vast majority of users do not have GPS-compatible end devices.

The possibility of unambiguous identification poses another problem. In case a mobile device gets lost, unauthorized persons may pretend to be the original user, as mobile devices usually have only a very low degree of security (Reisinger, 2007). This is especially a problem when users believe in the trustworthiness of the identification using mobile end devices.

Social Aspects

The electronic capturing and processing of the user context as well as the opening of communities for mobile usage can lead to negative consequences. Publishing the actual location of a user means an intrusion into his or her privacy and a limitation to intimacy. Being spied upon undiscovered could be the result of using contextual services. Parents could use these services to locate their children. Partners in a relationship could use it to track each other. The risks involved may lead to a fear of misuse or limited intimacy, resulting in the merely conditional use of contextual services. In stationary online communities, we observe that little emphasis is put on intimacy - users publish a multitude of personal data (Gross & Acquisti, 2005, p. 4-8). Hence, it remains open whether the added value of contextual services or the fear of misuse and limited intimacy will prevail.

At present mobile radio services, including SMS or telephony, are preferably used for contacting persons one already knows (Tasch & Brakel, 2004, p. 4). Stationary online communities are commonly used to create new relationships: i.e. contacting persons hitherto unknown to the user (Fremuth & Tasch, 2002, p. 24). The projection of mobile radio usage patterns onto stationary online communities could lead to the change from a preferably theme-oriented usage towards a person-oriented or communication-oriented usage of mobile online communities (Reichwald et al., 2002, p. 13). Mobile community activities would then be realized preferentially with already known persons. Such trends could jeopardize the establishment of theme-orientated mobile online communities.

Economic Aspects

A commercial design of mobile online communities has to identify primary and secondary revenue sources for their operators. Commercial intentions should be declared and openly communicated to the community (Leitner, 2003, pp. 43-44). This is the only way to grant trust and authenticity from the very beginning. Using primary revenue sources involves the following challenges:

- **Collection of usage fees:** So far, the stationary Internet largely provides free content and services (Reichwald, Fremuth, & Ney, 2002, p. 11). Internet users are accustomed to free services. There is a possibility that this factor will have a negative impact on the willingness to pay for mobile services. Users already pay for mobile data services such as SMS or mobile Internet access (Reichwald et al., 2002, p. 27). Fees for the use of services or content would increase these costs.
- **Advertising and sponsoring:** Advertising in online communities was often frowned upon in the past (Leitner, 2003, pp. 41-42). Even now, although an increased number of advertising banners are placed, the acceptance of advertising does not seem to be self-evident. Moreover, advertising messages on mobile devices are still fairly uncommon. It is unclear whether a satisfactory advertising effect can be achieved by mobile advertising in online communities. It is assumed that the perception duration of advertisement tends to drop with mobile usage compared to the stationary Internet (Heinonen & Stransdvik, 2007, p. 610; Reichwald et al., 2002, p. 22). Even when advertisements are noticed, little space for advertising messages is available due to the small displays of mobile devices (Michelsen & Schaale, 2002, p. 20).
- **Mobile data transmission fees:** As yet volume-billing models for the use of the mobile Internet are widespread; this could be a restriction to the time-consuming use of a mobile online community (Reichwald et al., 2002, p. 28). This can lead to lower data volumes, resulting in fewer payments to mobile radio operators. As a consequence, these operators would be less willing to forward payments to a community operator. It remains to be seen how this revenue potential develops through billing models for mobile Internet usage and cooperation.

There are also new challenges for the secondary revenue sources: Using a mobile online community as an instrument for market research can be profitable for an operator, but it seems reasonable that the users need to know that this is drafted on the basis of content and the analysis of their usage habits (Leitner, 2003, p. 43-44). This could especially affect success factors of an online community like equality, credibility and trust. Sharing part of the revenues with users could be a solution.

FUTURE TRENDS

A growing number of Internet services make their applications available to mobile users. This can be attributed to the increasing proliferation of mobile broadband Internet access (especially UMTS in Europe). Three variants of mobile implementation are available. Users can browse profile pages and photo albums via WAP and add new images and texts by means of SMS and Multimedia Message Service (MMS). The ShoZu service,[1] in contrast, performs as an integration platform and allows mobile users to upload and download content at multiple online communities with a single message. One Connect™ provided by Yahoo is another illustration which integrates social communities (e.g., MySpace, Dopplr, Facebook or Last.fm), instant messaging services (e.g., Yahoo! Messenger, MSN Messenger), and the ordinary communication channels of mobile phones. Finally, as the example of the COSMOS project[2] shows, a comprehensive use of mobile technical and social opportunities appears to be no so distant future—the COSMOS project integrates contextual services into the existing mobile social web. Users are informed about the geographical distance between them and may send messages to contacts within their own vicinity. The above-mentioned trends are expected to advance in the future; yet, the possible dominance of one of them cannot be predicted.

CONCLUSION

The analysis of the potentials of mobile online communities leads to the conclusion that the social significance of the mobile Internet goes further than providing communities with an additional access channel. Besides mobile access and instant connectivity, unambiguous identification and contextual services can also be realized.

The mobile web platform gains efficiency and facilitates not only flexible, spontaneous, and emotional interactions, but also credible and intensive ones. Reckoning with these possibilities, a community mobile operator can take an economic perspective and identify revenue sources that make the commercialization of mobile communities feasible.

However, the specific technical and social characteristics of mobile communities can cast doubt upon their prospective potentials. Commercialization appears less promising as the willingness of users to pay fees is rather low. Mobile advertising poses additional problems despite its context-relatedness. Moreover, the realization of secondary revenue sources can lead to problems of trust.

The assumption that the social significance of the mobile Internet will go beyond providing an additional access channel to online communities has so far only partially been confirmed. Many challenges to mobile communities remain to be resolved in the future for the economic perspective to gain relevance and the commercial interpretation to become a success.

KEY TERMS AND DEFINITIONS

Cosmos: The Community-Driven Systems Management in Open Source (COSMOS) project is a collaboration of software developers aimed to create standards-based tools for system management.

Mobile Internet: Use of TCP/IP based services and protocols with mobile devices via wireless communications technologies.

Mobile Social Web: Refers to mobile social networks and other Web 2.0-based applications in which people access and form online communities by using mobile devices.

Mobile Wireless Devices: Handheld electronic devices with wireless capability to connect to the Internet. Examples include mobile phones, smart phones, and personal digital assistants.

Mobility: Unrestricted transfer of text, voice or data independent of user's physical location.

Online Community: A social group that interacts through a web platform over an extended period of time.

Social Web: Refers to Web 2.0-based technologies and applications that are used to support communication and facilitate social contact, such as, social networking sites, massively multiplayer online role-playing games, photo and video sharing, online stores and auction houses, virtual worlds, and collaborative wikis.

Chapter 1.3
Social Semantic Web and Semantic Web Services

Stelios Sfakianakis
ICS-FORTH, Greece

ABSTRACT

In this chapter the authors aim to portray the social aspects of the World Wide Web and the current and emerging trends in "Social Web". The Social Web (or Web 2.0) is the term that is used frequently to characterize Web sites that feature user provided content as their primary data source and leverage the creation of online communities based on shared interests or other socially driven criteria. The need for adding more meaning and semantics to these social Web sites has been identified and to this end the Semantic Web initiative is described and its methodologies, standards, and architecture are examined in the context of the "Semantic Social Web". Finally the embellishment of Web Services with semantic annotations and semantic discovery functionality is described and the relevant technologies are explored

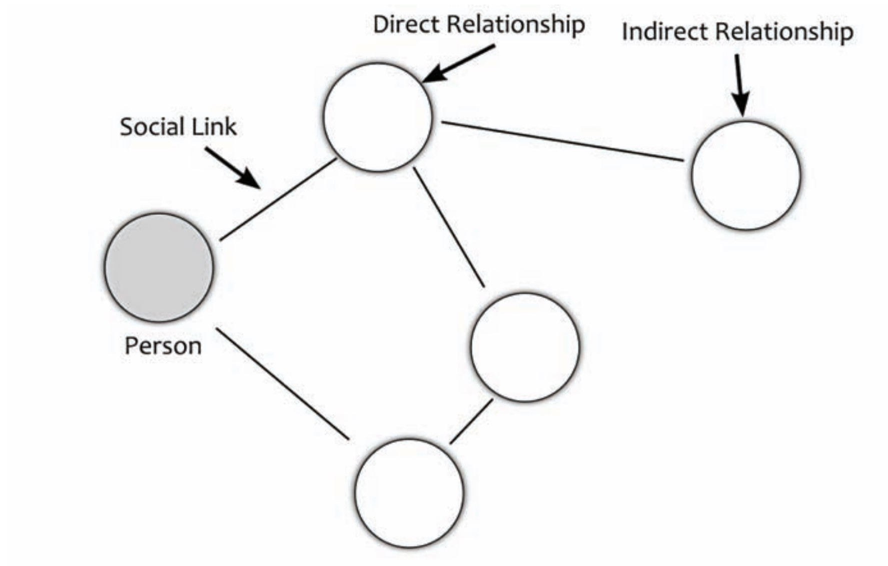
INTRODUCTION

The World Wide Web (WWW or, simply, the "Web") has been used extensively as a huge network of interconnected islands of data where documents are linked, searched for, and shared, forming a massive, albeit not always well organized, digital library. Sharing of digital content has always been the major requirement for the Web since its inception and will continue to be one of its most important features in the years to come. Nevertheless, what we experience nowadays is the endeavor for extending this sharing to cover also additional artifacts beyond plain documents, like data, information, and knowledge. The power of the hyperlinks, connecting different, possibly disparate entities, can also be exploited in order to connect information sources and people: not just "dumb" machine readable data but dynamic content like user profiles and ultimately people themselves for building virtual communities. The vision is that the current web of computers and documents will be broadened to the web of people. A "People Web" is the one where users are the nodes of the graph, the edges being their relationships and interactions in space and time, thus constructing new virtual societies (see Figure 1).

This new environment is leveraged by the introduction of an array of technologies collectively identified as Semantic Web (Berners-Lee, Hendler, & Lassila, 2001). The Semantic Web builds upon

DOI: 10.4018/978-1-60566-340-1.ch011

Figure 1. A social graph



the existing Web and provides the necessary substrate for giving "meaning" and "Semantics" to Web resources and Web interactions. The benefits will be many in a number of application domains and while the challenges, technological and other, are numerous, the momentum is strong and the Semantic Web slowly but steadily enters in a number of diverse domains like health and life sciences.

Furthermore the Semantic Web promises a great potential for supporting the construction and smooth operation of Web communities of people. In this chapter we study its fusion with social software and software for machine to machine communication over the Web for supporting this vision.

BACKGROUND

Since its launching in 1990, the Web has grown exponentially both in terms of size and in terms of use and utility to people and organizations. The inherent simplicity of hypertext and its feature limited, in comparison to previous hyper linking systems, one-way, inexpensive links (Universal Resource Identifiers – URIs) but also the employment of the Internet as its networking substrate led to its wide adoption and success.

In spite of its success and popularity the early version of the Web lacked in many respects, ranging from user accessibility and user interface design to the ability to repurpose and remix existing Web-based data in not pre-established ways. Although the hyper linking facility allowed the interconnection of different documents on the Web, the "traditional" Web suffers from fragmentation in the sense that the huge graph lacks any organization and discipline. This "anarchy" in the Web has also been its driving force for the success it has enjoyed so far but created the need for having special machinery, e.g. search engines like Google, to deal with the efficient indexing and discovery of the available information. Despite the fact that the search engine technology has made important steps in indexing and searching massive amounts of data on the Web, there's still the issue that keyword based searching is limited on its potential and usually finding "what the user wants" proves to be a tedious task. Another major limitation of this environment is that the people are not part of the equation. Users are expected to be the actors triggering the Web interactions but they are not allowed to participate and be involved enough in these interactions:

- Content delivered is not personalized. What the user gets back is usually not in-line with her interests or other preferences and there's no feedback link going from the user back to the system she interacts with so as to guide future interactions.
- Contextual information is not taken into consideration. The people as complex systems do not act in an easily predetermined way and the context of their actions is usually ignored or not taken advantage of. This context information ranges from the user's profile, which is also dynamic in nature, to the specific objective she/he is trying to achieve at a specific point in time.
- Content is passive and static, stored and maintained in back end databases, which the users do not have the ability to enrich or customize to their own needs
- Communication and collaboration of the users to build Web communities are not supported enough. Discussion forums were the sole way to build such communities but with no means to support intelligent integration of the different forums or to enhance the user collaboration experience.

These and other requirements are the ones that the Social Web tries to tackle. Social Web does not represent a shift or radical change in technology per se but rather a shift on the perception of the human – machine interaction by placing the users in the centre of the system and in control of these interactions. But from the other end of the spectrum there is also a clear need for making the Web itself more intelligent to support these machine facilitated social interactions. The Semantic Web could provide for such an enabling technology and recently the convergence of the Social and the Semantic Web and the experimentation of the two working in complementary ways have gained a lot of attention and research interest.

SOCIAL WEB OR WEB 2.0

The situation described in the previous section led to the emergence of a new breed of Web applications and sites that were collectively identified as "Web 2.0" by Tim O'Reilly (2005) and whose major design principle is to "*harness network effects to get better the more people use them"*. The value of "Web 2.0" sites and applications therefore comes to a large extent by the number of users participating and actively communicating and sharing through them so the term "*Social Web*" is actually a synonym. The social nature of this Web is evident when the collaboration of people and their active contribution is considered. The very essence of such sites is the building and maintenance of Web based *virtual communities* of people that produce and maintain *collective knowledge*. Examples of such community oriented and social networking sites include:

- Blogs, i.e. Web sites managed by individuals that provide news or opinions on certain subjects (typically personal online diaries), where typically other people are able to leave comments. In addition to comments, the hyperlinking facility of the Web has been extensively used to provide "trackbacks" (i.e. reverse hyperlinks that identify who is talking about me) and recommended blogs ("blogrolls"). Therefore blogging has been emerged as a method for anyone to publish content on the Web and building online communities of people that communicate, share, and integrate.
- "Social bookmarking" sites (e.g. http://del.icio.us/) where users can store and share their bookmarks with the additional

possibility to provide metadata through the means of tags, i.e. terms that denote concepts, meaning, intent, etc. These sites provide for user maintained and collaborative indexing of the Web content in a way that it may be more efficient to search there for something than in general purpose Web search engines.
- "Wikis" (e.g. http://en.Wikipedia.org), which are collaboratively built Web sites where the users, through custom made and user friendly interfaces, are able to create, share, enhance, and manage the content.
- Content sharing sites, e.g. YouTube (http://www.youtube.com/) for videos or Flickr (http://www.flickr.com/) for photographs, where the users upload their multimedia content and share it online with other users.
- Social networking sites, such as Facebook (http://www.facebook.com/) and MySpace, for online communities of people who share interests and activities or who are interested in exploring the interests and activities of others.
- Classified advertisement sites, e.g. Craigslist (http://www.craigslist.org), which offer advertisements for jobs, resumes, services, etc. grouped in categories.

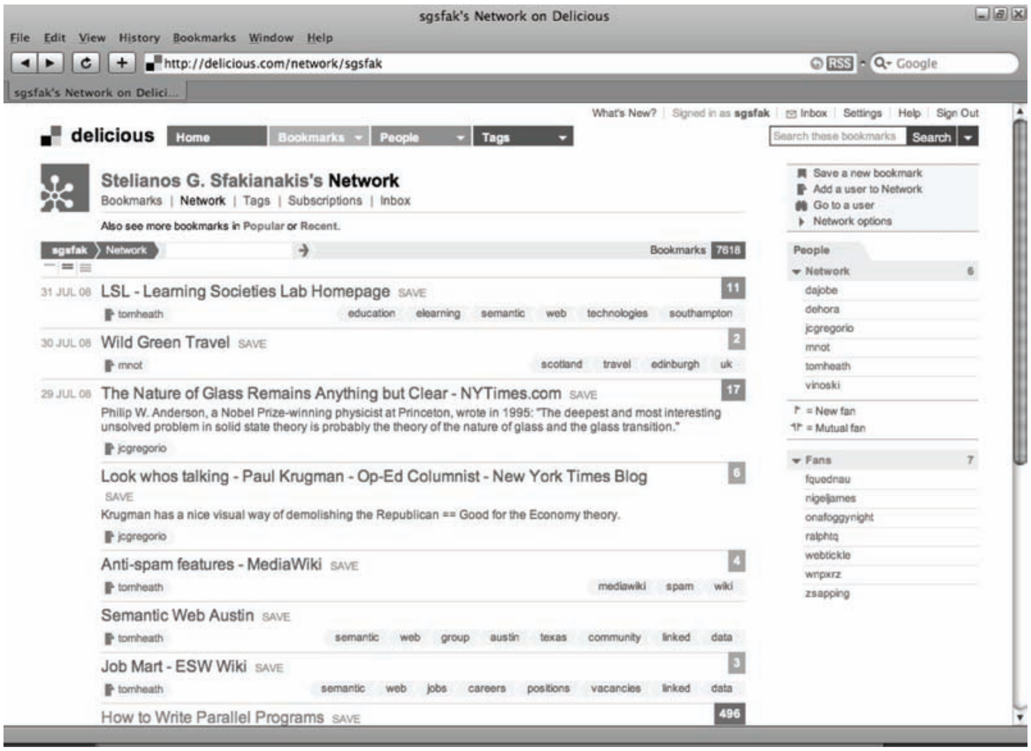
If we take only "Wikis" as an example we can see that these Web sites have been used in a multitude of ways:

- As online encyclopedias, e.g. Wikipedia
- As free dictionaries, e.g. Wiktionary (http://en.wiktionary.org)
- As free libraries of educational books, e.g. Wikibooks (http://en.Wikibooks.org)
- As software development repositories and issue tracking systems, e.g. Trac (http://trac.edgewall.org/)
- As open forums to promote research interests, like OpenNetWare (http://openwetware.org/) for biology and biological engineering
- As open educational centers to support learning activities, e.g. Wikiversity (http://en.Wikiversity.org/)
- As social event calendars, like Upcoming (http://upcoming.yahoo.com/)

The single distinctive feature of Wikis and a central trait of the social Web sites is the *user generated content* and its "open" editing: anyone can edit an existing Wiki article or create a new one for a particular topic if it doesn't exist already. The users therefore are responsible for adding content and maintaining the information that is available from these sites. Of course such an approach can raise a lot of concerns about the validity of the content, the lack of authority, etc.[1] and there have been cases in the past where such skepticism was proven true, such as the Seigenthaler incident[2]. Nevertheless this open model has worked quite well in practice and in general so that at the time of this writing Wikipedia is considered by many a serious competitor to the Encyclopedia Britannica. The reason for this can be explained as another instantiation of the "wisdom of crowds" phenomenon (Surowiecki, 2004): the participation of many people, possibly with different background, habits, way of thinking, and so on, in a decision making process usually yields better results than when the individual opinions are considered separately from one another.

The contribution of user content and the sharing of the uploaded information are the main forces for the formation of *online communities* of people. In Figure 2 an example of this community creation process is shown for the Del.icio.us online bookmarking site. Online bookmarking sites like this provide the means for storing and organizing bookmarks of Web sites on the Web instead of the users' desktop browsers. By storing their bookmarks in a central area the users are additionally enabled to create their online social networks by registering other users as members

Figure 2. Del.icio.us networks of users



of their network so that they can be notified about the bookmarking activity of these users. These networks therefore connect users with their friends, family, coworkers, or even totally strangers when they unexpectedly meet each other on the Internet and discover they have similar interests. Facilitated by these network links the users can subsequently observe each other's online behavior and even proactively send interesting Web sites addresses to their peers, easier and quicker than using email or instant messaging.

What the previous examples show is that in the Social Web users are in the limelight: they are the primary actors in the data sharing process through their contributions and online behavior. They are usually indulged by the low cost entry and participation in these Web sites, and, to a lesser extent, by the visual appeal the Web 2.0 sites offer to the viewer. The modern Web sites are actually Rich Internet Applications (RIA), where the majority of the business and control logic resides on the client (i.e. the Web browser), leveraged by technologies like AJaX[3] and Comet[4] which provide more responsive user interfaces.

The Social Web offers a meeting point for people to collaborate and share information in an open environment. The openness is a distinctive characteristic of Web 2.0 and it's supported by Open Data APIs like content syndication via RSS/Atom[5] and lightweight Web services interfaces like Open Search[6] . These technologies enable the view of Web sites as Web applications and their synthesis ("mashup") in more complex applications. An example of such combination of existing Web sites and their data to create new/aggregated content is Housing-Maps (http://www.housingmaps.com/) where houses to rent or buy are located through Craiglists and projected over geographic maps drawn from Google Maps (http://maps.google.com) so that a user can easily locate the information he wants in an interactive and visual way. A more general and reusable way to combine and "mix" content from different Web sites is offered by Yahoo! Pipes[7] which can be thought of a simple but effective way to build "workflows" and "dataflows" on the Web.

The above discussion shows that collaboration between people but also between Web sites/applications supports the notion of "collective intelligence" to the Social Web. An instance of this intelligence built collectively is the creation of "folksonomies" for categorization of resources. A quite popular way of classifying content in Web 2.0 Web sites is through "tagging". A tag is a keyword which acts like a subject or category. The user is allowed to attach whatever keywords she wants to identifiable content such as links in the case of social bookmarking, or videos and photographs in the case of digital content sharing. The important thing is that tags can be shared, used in searches, or recommended based on the choices of other users for the same content.

The new term "folksonomy", as a fusion of the words "folks" and "taxonomy", has been suggested to describe this method of classifying content through tags that are collaboratively generated and shared. Of course these "poor man's" classification schemes are informal in nature, could contain duplication in meaning, or be simply erroneous but again they are contributed by the users and the more people contributing the more robust and stable these "folksonomies" become. A self adapting and auto regulating method is usually followed through the use of tag clouds (Figure 3). In simple terms a tag cloud is a visual representation of a user's tags where each tag is weighted based on the user preferences and how many times he has used the tag. Through such an approach "good" tags are likely to prevail assuming that the user participation is high.

Collaboration, sharing, "mashing", annotating and "tagging" content are roughly the distinctive features of Web 2.0 and although in most of the cases the approach is not formal or the solutions are suboptimal the user participation and their socialization needs have driven the evolution of Web of documents to the Web of People (Ramakrishnan & Tomkins, 2007).

SEMANTIC WEB

To the other end of the spectrum, with roots in Artificial Intelligence research, the Semantic Web emanated as an extension to the current version of the Web that aims to enhance it by the promotion of higher level sharing and integration of data and information. According to Berners-Lee et al. (2001):

The Semantic Web is not a separate Web but an extension of the current one, in which information is given well-defined meaning, better enabling computers and people to work in cooperation.

The Semantic Web aims to support the representation and exchange of information in a meaningful way so as to make possible the automated processing of descriptions on the Web. The objective is to enrich the unstructured information in the current Web with machine processable descriptions of the Semantics in order to make its navigation and exploration by software agents as easy as it's for the human users today, or even easier. In this context Semantic Web promotes a shift from the current "syntactic" world to the future "Semantic" world of services, applications, and people and aims to make the machine to machine communication feasible so that not only data but also information and finally knowledge are shared.

The Semantic Web Technology Infrastructure

In technological terms the Semantic Web architecture consists of an array of technologies that can roughly be visualized in a layered design layout as depicted in Figure 4. The basic infrastructure in the bottom layers in this stack of technologies is

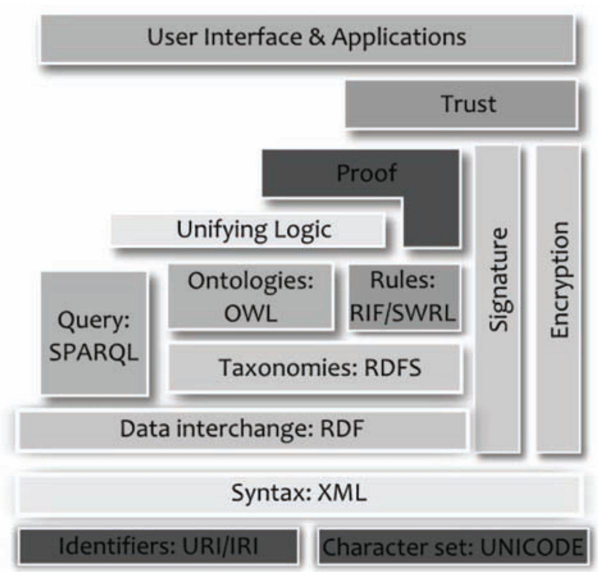
Figure 3. A tag "cloud"

the exactly the same to the syntactic Web: Uniform Resource Identifiers (URIs) used for identification of Web resources, universal encoding schemes for characters, i.e. Unicode, and XML and its related technologies (e.g. XML Namespaces) as a ubiquitous data serialization format. Some of the upper layers like Proof and Trust are missing or are work in progress. Here we will concentrate on the middle layers where the core infrastructure technologies of the Semantic Web reside: RDF, RDF Schema/OWL, and SPARQL.

The *Resource Description Framework* (RDF) is a syntax neutral data model that enables the description of Web resources in a simple way (Lassila, Swick, et al., 1999). At the core of RDF there is a model for representing and describing *resources* through named *properties* (also known as *predicates*) and their values. The resources can be anything that can be identified with a URI. Although in the initial specification of RDF resources were limited to Web documents and Web sites, it is possible and quite frequent in practice to describe, by the means of RDF and the various URI schemes, real world entities like people, or more abstract things like relationships and concepts. The use of URIs and especially the HTTP based ones for identifying persons or other physical entities may seem strange at first but this is in compliance with the architecture of the World Wide Web (Berners-Lee et al., n.d.) which strongly suggests the use of URIs for identifying anything that can be of importance irrespective of how abstract or tangible it may be.

The properties serve both to represent attributes of resources and to represent relationships between resources. They are also identified though URIs to make them unique. The combination of resources and the properties that connect them builds the simple RDF data model. In this data model the primary informational building block is the "triple" which denotes the subject – property - object expressions (Figure 5). The subject denotes the resource, and the predicate denotes traits or aspects of the resource and expresses a

Figure 4. The Semantic Web stack of technologies



relationship between the subject and the object. Since an object of a triple can be the subject of another one, a set of RDF triples forms a *directed graph* where the RDF resources, both subjects and objects, are the nodes of the graph and the predicates are the labeled arcs. As an example, in Figure 6 there's a simple RDF graph. The graph shown in the figure describes an entity identified through the URI "http://ssfak.org/stelios/", apparently denoting a person, which has a "name" property with the value "Stelios Sfakianakis", a property denoting the homepage of an organization a person works for relating it to the resource "http://www.ics.forth.gr/cmi-hta/", and a "maker" property that connects it (backwards, as an object) to the resource identified as "http://ssfak.org".

RDF as an abstract model is independent of any specific serialization syntax. The normative representation syntax for RDF graphs is XML but more lightweight formats, such as Turtle (Beckett & Berners-Lee, 2008), exist.

The simplicity and flexibility of RDF is evident but in certain cases its generality must be formally confined so that software entities are able to correctly exchange the encoded information. For example, stating that an animal is the creator of a Web page does not make sense in the real world but RDF does not forbid anyone for making such a claim. Ontologies (Uschold & Gruninger, 1996) provide such a tool to specify what can be expressed in the context of an application domain or in a real world scenario, what is the underlying meaning, and how the information presented can be further processed to generate more information.

Figure 5. RDF Data Model

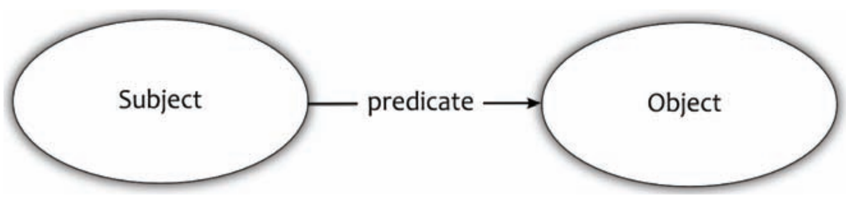


Figure 6. Abstract representation of RDF triples

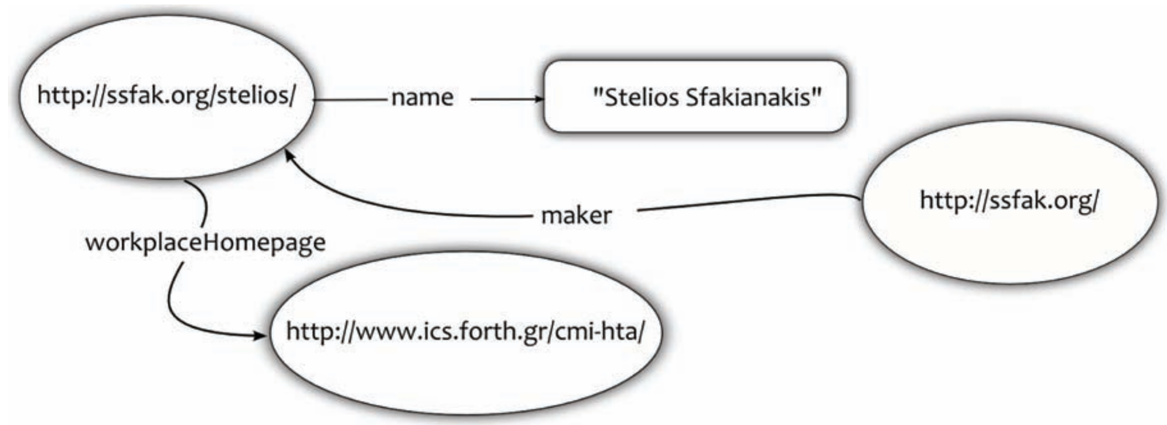


Moreover ontologies and their less powerful relatives like taxonomies and thesaurus provide the means for achieving a common interpretation of a domain and a shared understanding of the concepts and relationships involved. In the Semantic Web there are two main technologies for providing such rigor: RDF Schema and OWL (Brickley & Guha, 2004; Dean, Schreiber, et al., 2004). RDF Schema provides the means for defining classes, class hierarchies, properties, property hierarchies, and property restrictions. Its expressive power is basically limited to the representation of concepts, their relations, and taxonomies of concepts. On the other hand the Web Ontology Language (OWL) was introduced to address the need for more expressiveness and extends the RDF Schema by providing three variants: OWL-Lite, OWL-DL, and OWL-Full. Without delving into details, the different species of OWL provide different degrees of expressiveness and are able to define existential restrictions, cardinality constraints in properties, property types like inverse, transitive, and symmetric, and a lot more. The added features of OWL allow the ontologies built in conformance to it to be formally treated and the data represented are amenable to "reasoning" and inference, i.e. they can be processed according to formal logic rules to deduce new information. All these happen on the basis of the Web infrastructure: RDF resources and their URI references are used, the open world assumption is followed, since partial information on the Web is a quite frequent phenomenon, and the ontologies themselves can be freely intermixed and meshed since hyperlinks are employed everywhere.

Since RDF is the common interchange and representation model of information, the Semantic Web transforms the hyperlinked syntactic World Wide Web to a huge database or a Global Giant Graph, as Tim Berners-Lee put it. The standard query language for this huge database is SPARQL (Prudhommeaux & Seaborne, 2008), which is similar to SQL. In addition to the query language the SPARQL standard defines an application protocol for the submission of queries to RDF sources and the retrieval of results. With the query language and the access protocol defined, the SPARQL specifies a Web friendly interface to RDF information, whether this is actually stored as RDF triples or not. It is therefore feasible to make SPARQL queries to relational or other databases through an appropriate wrapper or transformation process that translates, either online or in some preprocessing step, the internal data to an RDF compliant format. As a result these Semantic Web technologies enable the connection of data between different and heterogeneous data sources, effectively allowing data in one data source to be linked to data in another data source. (Bizer, Heath, Idehen, & Berners-Lee, 2008)

SOCIAL SEMANTIC WEB

In recent years the cross pollination of Semantic Web technologies and Social Networking has emerged as an interesting roadmap. The Semantic Web technology can significantly enrich and expedite the Social Web in order to establish the *Semantic Social Web* (*Greaves, 2007;*Gruber, 2007*).* In the Semantics-enabled social Web content can be easily connected, integrated, navigated, and queried so that the benefits of today's Social Web can be greatly enhanced and augmented beyond the limited user experience offered by social networking sites alone or the restricted keyword based search and matching.

What does the Semantic Web offer to the Social Web? First and foremost, the Semantic Web technologies can be used to provide rigor and structure to the content of the user contributions in a form that enables more powerful computation. Currently social Web applications are more focused on the distribution and the management of content and the social interactions around it rather than the provision of Semantically rich descriptions of the data. Although there are popular, "low end" technologies like "microformats" and tagging/"folksonomies" to cater for the annotation and the description of data, these seem to be ad hoc and unstructured efforts in comparison to the formal Web ontologies and metadata descriptions. On the other hand, as already described, the Semantic Web promotes the global distribution and integration of resources in a single, giant, interoperable graph. So, additionally, the standards and infrastructure of the Semantic Web can enable data sharing and computation *across* independent, heterogeneous social Web applications.

Furthermore, the Semantic Web can enhance the Social Web with additional intelligence as Jemima Kiss (2008) wrote:

If Web 2.0 could be summarized as interaction, Web 3.0 must be about recommendation and personalization.

An example of such added value is the case of Semantic Wikis (e.g. Schaert, 2006; Völkel, M., Krötzsch, M., Vrandecic, D., Haller, H., & Studer, R., 2006). The Semantic Wikis support the annotation with Semantics descriptions the links and the content they provide and take advantage of these annotations for providing more intelligent search and navigation. The annotation is usually done by some extended version of the Wiki editing syntax so that every link to another page or any important attribute of the current page is annotated with a property identifier. For example in a Semantic Wiki's page about the Europe the amount of its population, which is a number, can be wrapped with the appropriate metadata that denote that this number represents the population. Such metadata annotation makes structured search easy, e.g. for queries like what is the population of Europe, or which continents have population above a certain amount. Additionally it facilitates the users in providing more active content in the pages by incorporating "online queries" in the Wiki pages, in the sense that the page's content can be dynamically generated by the results of these queries on the metadata annotations. Although the details may vary from one implementation to another, there's usually an underlying model based on RDF and OWL to support these Wikis and the content can be exported in a Semantic Web compliant format. DBPedia is an interesting example of a truly Semantic Web Wiki which offers the content of Wikipedia in a machine-readable and searchable format (Auer et. al., 2007).

In another application area, Semantic Web technologies can facilitate the browsing experience of people and the searching capabilities of the Web search engines. Unlike traditional search engines, which "crawl" the Web gathering Web pages information, Semantic Web search engines index RDF data stored on the Web and provide an interface to search through the crawled data. Because of the inherent Semantics of RDF and the other Semantic Web technologies, the search and information retrieval capabilities of these search engines are potentially much more powerful than those of current search engines. Examples of such early Semantic Search Engines include the Semantic Web Search Engine (SWSE, http://www.swse.org/), Swoogle (http://swoogle.umbc.edu/), and Zitgist Search (http://www.zitgist.com/). These and other Semantic Web search engines explore and index the documents of the Semantic Web and its ontologies by the means of user friendly interfaces that hide the details and complexities of the technology.

Blogs, which are one of the most prominent examples of the Social Web, can also be enhanced with Semantics. Augmenting a blog with content and structural metadata is usually called Semantic Blogging (Cayzer, 2004; Bojars, Breslin, & Moller, 2006). Putting Semantics in a blog's contents means that the topic of the content is described in a machine processable way. On the other hand describing the structure of the blog Semantically entails the description of the entities that compose it: the posts, the comments, the users, etc. To this end there are a number of efforts to make the Semantic Web more social by building new ontologies to support people in their social interactions and provide Semantics to the Social Web. Two of such ontologies, SIOC and FOAF, are of particular importance in the context of Semantic Blogging and are described below.

SIOC

Existing online community sites usually provide rich information for specific interest groups but they are isolated from one another, which makes difficult the linking and merging of complementary information among different sites. The Semantically-Interlinked Online Communities (SIOC) project aims to link online community sites using Semantic Web technologies. It defines methods to describe the information that communities have about their structure and contents, and to find related information and new connections between content items and other community objects. SIOC again is based around the use of *machine-readable information* provided by these sites.

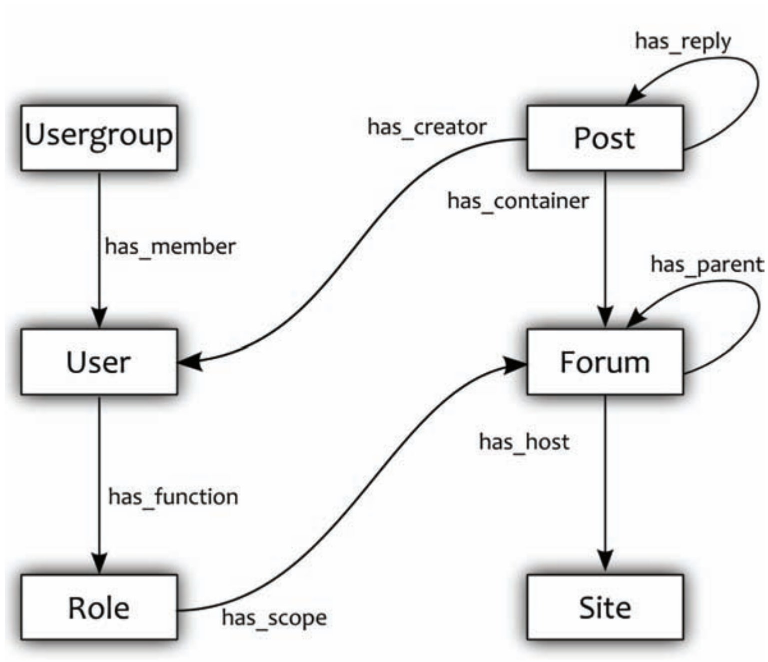
The main entities of SIOP are shown in Figure 7 and it's easy to see the role and the function of the main concepts. The entity Site refers to the location of an online community or set of communities, which hosts one or many blogs. A Forum can be thought of a discussion area on which posts are made. In a Forum a number of posts are contained where a Post represents an article or a message send by a user to the forum. Posts can be connected as people reply to previous posts and these connections can cross site boundaries since the identifiers of posts (as well as any Semantic Web resource) are universal and unique.

From the figure above it can be said that SIOP defines a common schema for the different blog sites and discussion forums. This of course needs not be their internal schema but a common, shared, and standard representation of their information model. Adopting SIOP therefore is a major step in achieving the integration of social content in Web 2.0.

FOAF

The Friend-Of-A-Friend (FOAF) project focuses on expressing mostly personal information and relationships in a machine-readable form. A central entity in the FOAF vocabulary and the one most frequently used is the Person (Figure 8). According to FOAF a Person may have names, e-mails, interests, publications, etc. It can also be connected to other resources like the Web site of the organization he/she works for (foaf:workplaceHomepage property), a personal blog site (foaf:weblog), the Website of his/her school (foaf:schoolHomepage), or to other people that he/she knows (foaf:knows).

Figure 7. The main classes and relationships of SIOC



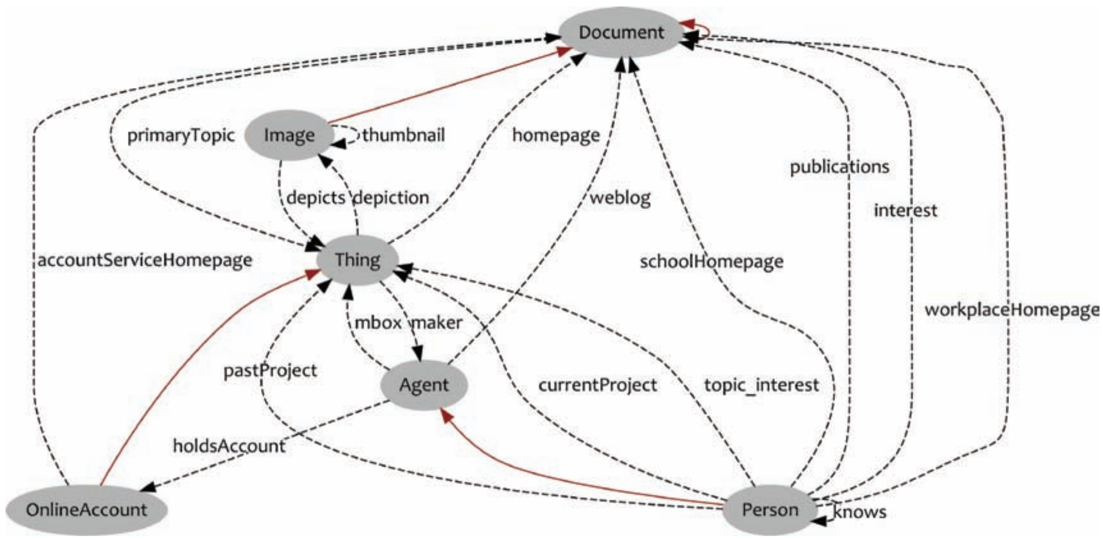
A lot of personal information can be therefore represented and parts of the real world's social graph can be inferred by following the foaf:knows relationship.

Of particular importance to the Social Web is the support the FOAF vocabulary offers to link the physical persons (foaf:Person) to the accounts they hold in a number of social Web sites (e.g. Flickr, Facebook) through the foaf:holdsAccount property. It is therefore possible through a single FOAF document that could be indexed in a Semantic Search engine to join all these different accounts and the information each of them exposes. Integration of different social content and behavior can be achieved and the resulting graph of information is searchable in an unambiguous and machine interpretable way.

Semantic Web Services

Application integration requires an agreed infrastructure to be in place for the exchange of information over the network. Over the last couple of decades there have been several attempts for defining such an infrastructure, such as Sun/RPC, CORBA, Microsoft's DCOM, Java RMI, and others. Currently Web Services are the favorite and most popular technology for building distributed systems over the Internet. As a middleware technology Web Services represent a new generation that tries to mitigate the problems of legacy integration technologies such as CORBA by adopting a more Web friendly substrate. Such a different approach seems to be needed in order to support business-to-business integration over the Internet where crossing organization borders has implications on the security, interoperability, scalability, maintenance, flexibility, and other aspects of application integration. In order to achieve these goals the Service Oriented Architecture (SOA) has been proposed. Informally speaking, in such architecture (Web) Services are network accessible entities that offer a number of functionalities to their callers. The SOA environ-

Figure 8. The main classes and relationships of FOAF



ment should be highly dynamic as suggested by a number of real world phenomena, like network instability, changing real world requirements and settings, etc. The need for "late binding" of services and clients is important and Figure 9, depicting the main entities of SOA and their interactions, shows that a middle service repository or registry is introduced. This repository stores "offers" of functionality as these are published by service providers, and subsequently performs matching with the corresponding "requests". After some matching has been performed the corresponding parties (services and their clients) are free to communicate and exchange data.

On the technology side Web Services put more emphasis on the following:

- Transport over widely accepted Web and Internet protocols like HTTP/HTTPS and SMTP
- XML message payloads to provide the extensibility, introspection, and interoperability required in building complex multi party systems
- Platform and programming language independence

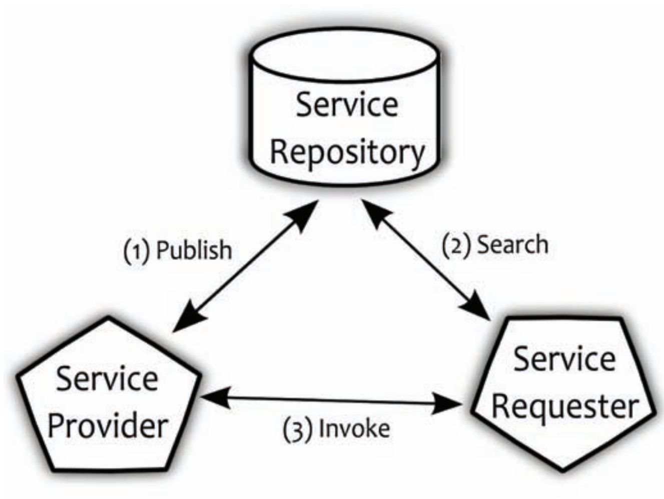
The Web itself is built around these very directions: open protocols, text based (markup, e.g. HTML) message and document content, and abstraction over implementation details. In essence the underlying infrastructure is roughly based on the following technologies:

- SOAP messaging format, which is based on XML, to provide a wrapper format and protocol for data interchange between Web services
- Web Service Description Language (WSDL) documents to describe the services' functionality and data exchange

On top of these a number of standard technologies have been specified for handling discovery (UDDI), security (WS-Security), trust (WS-Trust), composition (WSBPEL, WSCL), etc. Nevertheless for this discussion the WSDL standard is the most pertinent specification because it specifies in a machine readable format the structure of the XML messages exchanged.

Integration of computation and functionality is an additional field where Semantic Web shows a great potential of use because the Web

Figure 9. Web service architecture



Services, at their present incarnation, provide syntactic interoperability only. The WSDL service descriptions are restricted to the syntactic aspects of service interaction: how the service can be invoked, which operations may be called, what are the number and the type of the parameters each operation needs, etc. However, what the service does and in what order its operations have to be called in order to achieve certain functionalities is usually described only in natural language either in the comments of a WSDL description or in UDDI entries or other documentation. *Semantic Web Services* (McIlraith, Cao Son, & Zeng, 2001) is an "umbrella" definition to include the annotation of existing Web services with Semantics and their publication, discovery, and composition.

The vision again is to make feasible the machine to machine communication by providing machine interpretable descriptions of the services. Such descriptions will make possible the automatic discovery, composition, and invocation of services. Because of this a lot of efforts in metadata descriptions are centered on the Semantic Web and its technologies, namely RDF and OWL. In the area of the Semantic Web Services the following technologies and standards are relevant to the Semantic description of Web services:

- **UDDI (Universal Description, Discovery and Integration)** allows the discovery of potential business partners on the basis of the services they provide. Each business description in UDDI consists of a businessEntity element that describes a business by name, a key value, categorization, services offered (businessServices) and contact information for the business. Each businessService element contains descriptive information such as names and descriptions, and also classification information describing the purpose of the relevant Web service. Using UDDI, a Web service provider registers its advertisements along with keywords for categorization. A Web services user retrieves advertisements out of the registry based on keyword search. So far, the UDDI search mechanism relied on predefined categorization through keywords, but more recently specifications to use OWL in UDDI are emerging as a uniform way to express business taxonomies.
- **Semantic Annotations for WSDL and XML Schema** (SAWDL; Kopecký et. al., 2007) is a means to add Semantics inline to WSDL. It is actually a set of extensions to

WSDL 2.0 but can also be used for WSDL 1.1. With these extensions the service provider can attach references to Semantic concepts for the functionality of an operation or the type/meaning of a parameter and additional information for the transformation (mapping) of the XML data either to ("lift") or from ("lower") the corresponding Semantic terms. The Semantic domain model used is external to these annotations and could be expressed in OWL or other ontology language of choice.

- **OWL-S** (formerly DAML-S) builds on top of OWL and allows for the description of a Web service in terms of a Profile, which tells "what the service does/provides", a Process Model, which tells "how the service works", and a Grounding, which tells "how to access the service" (Martin et al., 2004). The service profile describes what is accomplished by the service, any limitations on service applicability and quality of service, and requirements that the service requester must satisfy in order to use the service successfully. The process model gives details about the Semantic content of requests, the conditions under which particular outcomes will occur, and, where necessary, the step by step processes leading to those outcomes. In the process model a service can be described as an atomic process that can be executed in a single step or a composite process that, similar to a workflow, can be decomposed in other processes based on control structures like 'if-then-else' and 'repeat-while'. Finally, Grounding descriptions supply information about the communication protocol and other transport information (such as port numbers) and the message formats and serialization methods used in contacting the service. The only currently specified grounding mechanism is based on WSDL 1.1 and will be extended to WSDL 2.0 as soon as it's finalized.
- **The Semantic Web Services Framework (SWSF)**, initiated by the Semantic Web Services Initiative (SWSI, 2004), includes the Semantic Web Services Language (SWSL) and the Semantic Web Services Ontology (SWSO). SWSL is a logic-based language for specifying formal characterizations of Web service concepts and descriptions of individual services. SWSO is an ontology of service concepts defined using SWSL and incorporates a formal characterization ("axiomatization") of these concepts in first-order logic.
- **WSMO (Web Services Modeling Ontology)** defines the modeling elements for describing several aspects of Semantic Web services (Feier et al., 2005). These elements are Ontologies, which provide the formal Semantics to the information used by all other elements, Goals which specify objectives that a client might have when consulting a Web service, Web services that represent the functional and behavioral aspects which must be Semantically described in order to allow semi-automated use, and Mediators that are used as connectors and they provide interoperability facilities among the other elements. It also defines the Web Service Modelling Language (WSML) which formalizes WSMO and aims to provide a rule-based language for the Semantic Web.
- **BioMOBY** (http://www.biomoby.org/) is a Web Service interoperability initiative in the field of bioinformatics aiming to facilitate the integration of Web-based bioinformatics resources. Currently there are two approaches to achieve such integration: The first approach, based on the Web Services paradigm, is referred to as "MOBY Services" (MOBY-S), while the second one is called "Semantic MOBY" (S-MOBY) and is based on concepts from

the Semantic Web. MOBY-S uses a set of simple, end-user-extensible ontologies as its framework to describe data Semantics, data structure, and classes of bioinformatics services. These ontologies are shared through a Web Service registry system, MOBY Central, which uses the ontologies to Semantically bind incoming service requests to service providers capable of executing them. S-MOBY on the other hand employs RDF and OWL and the document oriented infrastructure of the WWW (the GET/POST methods of HTTP) for publishing and retrieving information from its discovery servers.

As shown above this is an area of active research. So far SAWDL enjoys the approval of W3C being one of its recommendations but of course is lacking when compared with WSMO and OWL-S. Nevertheless SAWSDL can be combined with these most prominent technologies and it remains to be seen whether such approaches are adequate or something more powerful should be introduced.

CONCLUSION

The social aspects of the Web show an uprising evolution and all the indications imply that this trend will continue. The current Web 2.0 sites are quite successful in attracting people share their data and interests, and build online communities, but the next step will be to enrich them with more Semantics in the lines of the Semantic Web to provide a unifying platform for people and machines to use and collaborate. The need for Semantics (Breslin & Decker, 2007) is evident for enhancing the social networking sites with advanced filtering and recommendation services and also to provide data portability and integration between different sites and networks. This is an active area where the Semantic Web technologies can greatly help.

There have been a lot of discussions about what will be the "killer application" of the Semantic Web, which means some breakthrough in the domain that will show beyond any doubt the full potential of the Semantic Web. Nevertheless we think that Semantic Web technologies are used slowly and without much "noise" in a lot of different areas and as "extension to the existing Web" are not clearly visible but are certainly catching on. There is a common view nowadays that the Semantic Web will not supersede the Syntactic Web in any way but they will happily coexist in a symbiotic manner: the Web of documents will be enriched by the Web of data and information.

In terms of the core infrastructure what we see as emerging trend is the use of simple REST Web services (Fielding & Taylor, 2002) that present a small entry barrier and a transition from the SOAP and WSDL Web Services technologies backed by big commercial corporations like IBM and Microsoft to more flexible and agile architectures. These architectures are more bound to the existing Web and also are more Semantic Web friendly since they share common basic infrastructure and interaction protocols (e.g. Web protocols like HTTP used as application protocol and not for transport, full support for URI to access network resources and Semantic concepts, etc.). The whole history of the Web clearly shows that successful distributed systems of this scale are built on open access, open protocols, and open source methodologies combined with collaborative behavior by the people (developers, users) involved.

Research questions and issues for further investigation abound in this Semantic new world. First of all the issue of trust and security and how this is incorporated in the Semantic Web machinery should be tackled on. For example currently a user can claim anything in his FOAF document, or a malicious application can publish RDF information that contains false statements. The notion of identity and validation of the identity is important and there is ongoing work in this area, e.g. the incorporation of user certificates or Web based authentication mechanisms like OpenId[8]. Semantic Web has also increased demands for supporting indexing and reasoning over the managed content. The scalability concerns are real when we think about a Semantic Web search engine of the size of Google. Finally the adoption of these technologies by the users needs work to be done in the presentation layers as well. Easy to use, friendly, and functional user interfaces are necessary for making the transition to the Semantic Web more painless and transparent for the users.

KEY TERMS

Semantic Web (SW): The creator of the World Wide Web Tim Berners-Lee defines the SW as "a web of data that can be processed directly or indirectly by machines". A similar definition coming from the World Wide Web Consortium (W3C) describes the Semantic Web as "a Web that includes documents, or portions of documents, describing explicit relationships between things and containing Semantic information intended for automated processing by our machines."

Social Web/Web 2.0: The way people socialize and interact with each other through the World Wide Web. This term is also used to denote a large number of Web sites that are devoted to people and their social interactions through the creation of online communities of users that share digital content and information, discuss, or enable communication in any possible, Web-facilitated way.

Web Service (WS): A Web Service is defined by the World Wide Web Consortium (W3C) as "a software system designed to support interoperable machine-to-machine interaction over a network". Since this definition is quite general the term "Web Service" commonly refers to systems that communicate using XML messages that comply with the SOAP messaging format. In such systems, there is often machine-readable description of the operations offered by the service written in the Web Services Description Language (WSDL).

Klaus Moessner
University of Surrey, UK

ABSTRACT

The world becomes ubiquitous, and mobile communication platforms become oriented towards integration with the web, getting benefits from the large amount of information available there, and creation of the new types of value-added services. Semantic and ontology technologies are seen as being able to advance the seamless integration of the mobile and the Web worlds. We provide background information on the Semantic Web field, discuss other research fields that bring semantics into play for reaching the ontology-enabled ubiquitous mobile communication vision, and exemplify the state of the art of ontology development and use in telecommunication projects.

DOI: 10.4018/978-1-60566-028-8.ch011

INTRODUCTION

Nowadays, mobile and Web environments converge in one shared communication sphere. Technologies stemming from Semantic Web and Mobile Communication fields get combined to achieve this convergence towards the vision of ontology-enabled ubiquitous mobile communication. Knowledge Management and Semantic technologies fields produce ways to describe, specify and manage information in a machine processable form, in particular, acquire, evolve, reuse, and combine knowledge (Fensel, 2001). Certain formats and protocols stemming from these fields are already being applied to telecommunications: vCard[1], CC/PP[2], UAProf[3]. However, these specifications are only applicable to a limited number of telecommunication scenarios, and management of information about resources in mobile environment could be substantially improved, e.g., by alignment of heterogeneous information sources in knowledge-based service enablers.

Ontologies and architecture knowledge layers play an ever-increasing role in service platforms and mobile communications. As integration of Telco, Internet and the Web takes place, in order to achieve interoperability, telecommunication systems and services tend to rely on knowledge represented with the use of shared schema, i.e., on ontologies similar to as envisioned on the Semantic Web (Tarkoma et al., 2007). However, specific ontology-based implementation solutions for mobile systems are rare, and best practices for such interoperability are not established. In this chapter, we address a problem of ontology-based interoperation in order to integrate independent components in a system providing value-added mobile services.

We present the overall state of the art ontology-related developments in mobile communication systems, namely, the work towards construction, sharing and maintenance of ontologies for mobile communications, reuse and application of ontologies and existing Semantic Web technologies in the prototypes. Social, collaborative and technical challenges experienced in the project showcase the need in alignment of ontology experts' work across the mobile communication projects to establish the best practices in the area and drive standardization efforts. We indicate certain milestones in integration of Semantic Web-based intelligence with Mobile Communications, such as performing ontology construction, matching, and evolution in mobile service systems and alignment with existing heterogeneous data models.

The chapter is structured as follows. In Section 2 we provide a motivation for discussing the convergence between the areas of Semantic Web and ubiquitous mobile communications. Section 3 gives an overview of the core ontology technologies involved, related and relevant research and development fields and challenges in the area. In Section 4, two illustrative case studies for the converged area are described. Section 5 concludes the chapter and Sections 6 indicates future research directions.

WHY SEMATICS IN UBIQUITOUS MOBILE COMMUNICATIONS?

In this section we motivate why combination of Semantic Web technology with ubiquitous mobile communications is beneficial. Semantic technologies in mobile communication have been somewhat considered to the less extent comparing to other fields, such as semantics in e-sciences, e-government, e-enterprise, e-communities, etc. However, as the mobile world starts to integrate with the Web world in delivering new value-added services, the area of semantics ubiquitous mobile communication inevitably gains a larger importance and potential.

Ubiquitous computing, also referred to as pervasive computing, is the seamless integration of devices into the users every day life. Applications should vanish into the background to make the user and his tasks the central focus rather than computing devices and technical issues (Weiser, 1991). When applying to mobile communication scenarios, ubiquitous computing can be viewed as when user moves around and changes circumstances, he can always be connected and well served without being aware of the technical issues under the scene. To achieve the goal, information from all the involving participants, such as user, network, service provider etc., needs to be collected, shared and interoperable with each other, known by one or more operational agents but agnostic to the user. Such information is diverse in their language, format and lack of semantic meaning for autonomous processing by computer or operational agent. The Semantic Web can be a rescue with its vision to achieve global information sharing and integration.

An example of combination of the two fields can be a service enabler that could be used by other services and thus make their construction simpler. For example, such an enabler could access distributed information on user's location, availability and friends and inform other services about which groups of friends are available and located at the same place. Services that assist with scheduling business meetings or parties, or the ones that are targeted at selling products for groups of users can be among the services that need such information from the enabler. To achieve the output, the enabler would take external structured data represented in a formal way (e.g., in RDF): for instance, information about user's availability from PIDF files, information on who is a friend of whom from FOAF profiles, information about location from data stemming from such standards as IETF RFC4119, RFC4589. Then the enabler would combine the gathered information, apply certain rules to deduce the result and pass it to other mobile services via an interface.

GROUNDING FOR SEMANTICS IN UBIQUITOUS MOBILE COMMUNICATIONS

In this section, we describe existing developments relevant for the combined field of ubiquitous mobile communications and the Semantic Web.

Ubiquitous Mobile Communication Existing Developments

A lot of work has been undertaken to implement the vision of ubiquitous mobile communications by investigating the underlying technologies. Examples include, but not limited to, user-related context collection, such as sensor network, Bluetooth, GPS, user-related context modelling and transmission, such as CC/PP, UAProf, 3GPP, MPEG-21, multimedia content description, such as MPEG-7, service discovery and service context modelling, such as UPnP, Jini, Bluetooth SDP, agent technologies, such as FIPA, ACL. Network mobility, security and QoS management, such as Hierarchical mobile IP, IPSec, DiffServ etc. The combination of these technologies with Semantic Web has become an inevitable trend in a ubiquitous mobile communication environment. Some of such joint developments are presented later in Section: Relevant research fields.

Semantic Web Existing Developments

Existing developments of the Semantic Web include languages (i.e. core formalisms to specify domain knowledge or services), methodologies and tools. In this section we outline the major developments in these areas and indicate their role and contributions in the area of Semantic Web enabled mobile platforms.

Languages and Formalisms

RDF(S)

RDF (Lassila & Swick, 1999; Manola & Miller, 2004) became a W3C recommendation in 1999. It is a general-purpose language for representing resources on the web in terms of named properties and values (McBride, 2004). With RDF it is not possible to define the relationships between properties and resources. For this purpose, RDF Schema (Brickley & Guha, 2004) has been specified. It became a W3C recommendation in 2004 and is basically an extension of RDF. More specifically, it is a formal description language for eligible RDF expressions. In particular, a schema defines the kinds of properties available for resources (e.g., title, author, subject, size, colour, etc.) and the kind of resource classes being described (e.g., books, Web pages, people, companies, etc.). RDF Schema is a simple ontology and a simple ontology definition language. RDF and RDF Schema are usually denoted RDF(S).

RDF(S) bases on some syntactical principles of XML (e.g. URIs) and has been equipped with an XML syntax as well. The most basic Semantic Web language which provides the syntactical basis for all other Semantic Web languages is RDF(S). RDF(S) is not provided completely with a formal logical semantics, thus reasoning is only on partially supported.

Topic Maps

Topic Maps are a data modelling language and became an ISO standard (ISO/IEC 13250) in 2000. A Topic Map offers a means to create an index of information which resides outside of that information. It describes the information in documents and databases by linking into them using URIs. A Topic Map consists of topics, associations (relationships between topics), occurrences (information resources relevant to a topic). Topics and occurrences can by typed. Types in Topic Maps are themselves topics and thus there is no real difference between a topic and a type.

There exists SGML, XML and RDF language support for Topic Maps. However, they are very simple and do not have a formal semantics and thus no sophisticated inference support. Nevertheless, because of their simplicity, they are often used in industry applications.

OWL

OWL (Dean & Schreiber, 2004) became a W3C recommendation in 2004. OWL is mainly based on OIL and DAML+OIL, which are obsolete Semantic Web languages and therefore not mentioned further here. OWL is equipped by an RDF syntax and includes three sub languages:

OWL-Lite roughly consists of RDF(S) plus equality and 0/1-cardinality. It is intended for classification hierarchies and simple constraints. OWL-Lite corresponds semantically to the formal Description Logic *SHIF(D)* and cannot express the whole RDF vocabulary.

OWL-DL contains the language constructs of OWL-Lite. OWL-DL corresponds semantically to the Description Logic *SHOIN*(D). Although strictly more expressive than OWL-Lite, it still provides computational completeness and decidability.

OWL Full does not correspond to a formal logic anymore as it builds upon the complete RDF(S) vocabulary which also lacks a correspondence to a formal logic. The language incorporates maximum expressive power and syntactic freedom, but offers no computational guarantees.

Semantic Web Languages in Progress

In this subsection, we consider Semantic Web languages which have been submitted to the W3C and thus have communities promoting them. At least some of them can be expected to become W3C recommendations. Examples of such languages are:

- *Languages based on the Logic Programming Knowledge Representation paradigm*: The trend to the aforementioned paradigm exists already since the year 2000 when the development of RuleML[4] has started. RuleML is a set of languages revolving around the Logic Programming paradigm and being equipped with an RDF syntax. Other examples of Semantic Web Languages with Logic Programming semantics are WRL[5], a set of three layered rule languages of increasing expressivity, and SWRL[6], a language which combines OWL and RuleML but is computationally intractable. Furthermore, a W3C working group[7] has been formed for establishing standards for Semantic Web rule languages.

- *Semantic Web Service Modelling Languages*: Semantic Web Services will play an important role in the Semantic Web as they combine Web Services with semantics. Examples for Semantic Web Services Languages are WSML[8] and SWSL[9]. The languages serve for the specification of ontologies describing Semantic Web Services. E.g., WSML is used to describe WSMO[10] and SWSL is used to describe SWSO[11].

Ontologies and Tools

Apart from the languages to describe data, specific ontologies related to the mobile communication domains and appropriate ontology management tools are necessary to implement the vision of ubiquitous mobile communications.

In a nutshell, the state of the art in development of the ontologies addressed by ubiquitous mobile communications comprises:

- Ad-hoc small-size schemata on certain general purpose topics are specified in ontology languages.
- Detailed, XML-based standards on certain narrow telecommunications topics.

Certain standardisation schemata and activities to be considered for the development of the ontology framework for mobile communications are listed later in Section: Mobile Ontology. Additional efforts coming from the Semantic Web community are listed in Table 1.

Typically, existing ontology management tools are adopted and explored in the semantic telecommunications projects. Stemming from the SPICE project (Zhdanova et al., 2006), examples of relevant and popular ontology management tools used, as well as encountered problems in their exploitation and an expected resolution times, are provided in Boxes 1 and 2.

As the ontology data are processed within the ubiquitous mobile communication applications, exploration and reuse of further ontology management technology is on the roadmap of the research and development field.

Major Challenges and Approaches

In this section, we define major challenges that are under development or need to be developed in the joint area. From ubiquitous mobile communication point of view, the challenges can be viewed from three perspective, i.e., from the user, the network operator, and the service provider. From user's point of view, there is an expectation of autonomous, non-stop service being provided with satisfying quality whatever terminal he/she uses, whenever he/she needs and wherever he/she goes without having to set the configuration. From network perspective, there is a challenge of ensuring the service delivery by providing a smooth handover, a guaranteed QoS and security level etc. when delivery circumstance changes, for example, from one type of network to another. From service provider point of view, the anticipation is to provide only one version of service, which, however, can be used by any device via any networks. To face these challenges, when designing a ubiquitous service delivery based on ontologies, the information from and about the user, network condition, the content/service being provided, together with any context information (to support personalization and service push to the user), need to be described in an unambiguous and interoperable manner in order to perform effective service delivery. Therefore, common ontologies describing such domain knowledge, as well as best practices in their reuse are required. Generally, challenges faced from ontology point of view include:

- **Heterogeneity:** Resolving inconsistencies, format differences (syntactic and semantic

Table 1. Ontologies related to the mobile ontology

Ontology Name	Producer	URL	Description	Development Status
MeNow	Chris Schmidt	http://crschmidt.net/foaf/menow/menow.rdf	The motivation for the MeNow schema is to be able to describe a variety of aspects of the current status of someone, either online or off, in a way that the data can be easily aggregated or retrieved. This schema allows the definition of a variety of terms that would be common in many applications: describing the current book you are reading, music you are listening to, mood you are in, and more.	
Pervasive SO – Describing User Profile and Preferences	Harry Chen, UMBC	http://pervasive.semanticweb.org/doc/ont-guide/part1/	Pervasive Computing Standard Ontology (PERVASIVE-SO) is a set of RDF/OWL ontology documents. Each ontology document is identified by a unique XML namespace and defines the ontologies of a specific domain. In a pervasive computing environment, computer systems often need to access the profiles and the preferences of a user in order to provide services and information that are tailored to the user. The profile of a user includes typical contact information (telephone numbers, email addresses, name, etc.) and information that describe other computing entities that can act on the behalf of the user (e.g., the personal agent of a user). The preference of a user is a description of the environment state that the user desires the computer systems to honor or achieve whenever it is possible.	Frozen in 2004
Platform for Privacy Preferences	Brian McBride, HP	http://www.w3.org/TR/p3p-rdfschema/	The Platform for Privacy Preferences Project (P3P) enables Web sites to express their privacy practices in a standard format that can be retrieved automatically and interpreted easily by user agents. P3P user agents will allow users to be informed of site practices (in both machine- and human-readable formats) and to automate decision-making based on these practices when appropriate. Thus users need not read the privacy policies at every site they visit.	Frozen in 2002
Gadget	Morten Frederiksen	http://www.wasab.dk/morten/2004/10/gadget	Definitions of various terms related to (typically) electronic gadgets such as GPS receivers, cameras and mobile phones.	Frozen in 2004
ConOnto: Context Ontology	Mohamed Khedr	http://www.site.uottawa.ca/~mkhedr/contexto.html	ConOnto describes the different aspects of context-aware systems. ConOnto includes location, time, activities, software and hardware profiles. ConOnto also includes meta-information that describes negotiation and fuzzy ontologies to be used in systems that will negotiate and infer about context information.	
Ambient Networks: General, Cost, QoS Ontology	Anders Karlsson, TeliaSonera	http://kiwi.intra.sonera.fi/an_costs.owl		Created in 2005

differences in formalization), business process mediation.

- **Versioning** when merging or combining ontologies representing different knowledge domains, ontology and instance data evolution and maintenance during updates.
- **Scalability:** Scalable repositories for ontology instance data (currently popular ontology management toolkits such as Jena and Sesame do not always meet industrial standards).
- **Ontology and instance data visualization**, user interfaces.
- **User/community generated content:** formalization, acquisition and employment (when building innovative mobile services in Web 2.0 style of social applications alike to YouTube, Flickr, LinkedIn, Google Base, etc.).
- **Semantically described mobile and web services** (no yet widely accepted "standard" solutions).
- **Service composition and discovery**, user-driven creation of new services by composing service enablers, mash-ups.
- **Integration with the non-semantic web services and formats**, which use traditional technologies such as WSDL, SOAP and UDDI, XML.
- **Integration with legacy applications**, which are not terminologically a service, but can be upgraded to be a service, e.g. MPEG codec.

Relevant Research Fields

The following research areas are related to, impact and will be potentially impacted by the described involvement of the Semantic Web in Mobile Communications.

Multimedia

Today, the amount of digital multimedia information is growing over the World Wide Web, in broadcast data streams and in personal and professional databases. One of the major challenges for ubiquitous mobile communication is to enable any mobile devices, e.g. mobile phone, PDA, to access, exchange and consume a rich set of multimedia content seamlessly over dynamic and heterogeneous networks. The need of semantic description of the multimedia information becomes apparent. The MPEG-7 and MPEG-21 are the dominant efforts for multimedia content and service description framework.

MPEG-7 is known as the multimedia description standard and offers several tools, i.e. Description Schemes, to annotate multimedia content at different levels. The main parts are: Description Definition Language (DDL), Visual, Audio and Multimedia Description Schemes (MDS). The DDL is a language that allows the creation of new Description Schemes and, possibly, Descriptors. It also allows the extension and modification of existing Description Schemes. The DDL is based on XML Schema Language, but with MPEG-7 extensions specifically for audiovisual description. The Visual description tools provide structures to describe basic visual features, such as color, texture, shape, motion and localization etc. The Audio description tools provides structures for the description of audio features that are common across many applications, such as spectral, parametric, and temporal features, and that are application-specific features, such as audio indexing, recognition and signature. MPEG-7 Multimedia Description Schemes provides the description tools for generic media entities, such as vector, time and more complex media entities. The latter can be grouped into 5 different classes according to their functionality: Content description, Content management, Content organization, Navigation and access and User interaction.

MPEG-21, the 21st century multimedia framework, goes further and provides tools to describe the environment to enable transparent multimedia creation, delivery and consumption between heterogeneous environments. The main parts are Digital Item Declaration (DID), Digital Item Identification (DII), Intellectual Property Managements and Protection (IPMP), Rights Expression Language (REL), Rights Data Dictionary (RDD) and Digital Item Adaptation (DIA). The Digital Item Declaration (DID) specification contains three normative sections, a model to describe a set of abstract terms and concepts to form a useful model for defining Digital Items, a representation to describe the syntax and semantics of each of the Digital Item Declaration elements, and a Schema comprising the entire grammar of the Digital Item Declaration representation in XML. The DII specification provides mechanisms to uniquely identify Digital Items, Intellectual Property related to the Digital Items such as abstractions, Description Schemes and types of Digital Items. IPMP is an extended efforts based on MPEG-4 to develop new systems and tools with enhanced interoperability. The REL, together with the RDD that supports the REL and provides extensive semantics, provides a universal method for specifying rights and conditions associated with the distribution and use of digital items and thus facilitates the creation of an open DRM architecture. DIA provides tools to describe the Digital Item usage environment including: Usage characteristics, such as user info, usage history, User preferences and physical characteristics such as disabilities, Device characteristics such as display, memory and battery, Network characteristics, such as error characteristics and bandwidth, and Natural environment characteristics such as noise and illumination. This is to facilitate transparent access to distributed digital items by shielding users from the technical complexity, such as network and terminal installation, management and implementation issues.

Web Service (SOA)

Service-Oriented Architecture (SOA), especially a Web service-based SOA, has the potential in speeding up the application development process and the agility in responding to the change of business needs. This is due to the loose coupling of client from service and the set of standard protocols and technologies used by the Web service, such as XML, WSDL, SOAP, and UDDI. The inherent features of SOA, i.e. reusability, interoperability, scalability and flexibility, can virtually meet the requirement of a supportive framework for ubiquitous mobile communication.

Coming along with Semantic Web is Semantic Web service, where Web service is described with added computer-processable semantics, and thus a number of services can be concatenated autonomously to compose a new service for a more complex task. This will benefit service provision in a ubiquitous environment where all information from user, network, together with the requested service and any intermediate service are required to make a delivery decision autonomously. In accordance with this advance, the set of standard protocols and technologies for Web services are evolving to reach their semantic counterparts or brand new standards are created. For example, the ontology languages, RDF, RDFS, and OWL are developed to add computer-processable semantics on top of the exiting syntax provided by XML. WSDL specifies a way to describe the abstract functionalities of a Web service and concretely how and where to invoke it. Semantic Annotations for WSDL (SAWSDL)[12] defines mechanisms using which semantic annotations can be added to WSDL components based on an earlier effort, namely WSDL-S[13], which adds semantic expressivity to the service description by extending original WSDL elements. SOAP, as the message exchange protocol and originally XML-based, can be combined with RDF and OWL in order to introduce semantics to assist the flexible service invocation (Zhao, 2004). Similarly, enabling UDDI to store semantic markup and handle semantic enquiries has been investigated in recent years (Luo et al., 2006). Correspondingly, service-oriented architectures require machine-processable semantics to achieve its full potential. In particular, DERI[14], targets this challenge by offering a set of tools and techniques ranging from ontology construction to description language. The later include Web Service Modelling Ontology (WSMO), Web Service Modelling Language (WSML) and a Web Service Execution Environment (WSMX)[15].

Security, Privacy, Trust

In recent years, the security and trust aspects of Web services are standardised by OASIS[16] with a WS-security specification released in 2004. WS-security insets security-related information to Web service messaging that provides for message integrity and confidentiality using security token and digital signatures. The use of Semantic Web technologies enables Web into a genuinely distributed and global content and service provider. Inherent with this are the issues of more widespread security, trust, information quality and privacy.

To achieve a security solution for Semantic Web service, the traditional security solutions can be described as one of the contextual information attached to the service and can be interpreted on the other end at semantic level. This solution has the advantage of not requiring to design a bottom-up Semantic Web service security architecture and thus provides the service provider with flexibility of control. However, embedding security and trust policies into every Web service may not appear to be an attractive solution and can result in tight coupling between services and particular security implementations. An alternative is to design an integrated Semantic Web security framework with security mechanisms available at various layers of the network. This may provide a comprehensive solution when more security and trust issues and challenges arise from the traditional communication domain. For example, when seamless interconnecting heterogeneous networks, particularly when security issue are jointly considered with other issues, such as QoS and mobility management, in the overall communication process.

Human Communication Interface

The design of the Human Communication Interface (HCI) for Web applications has always been of great importance. The Web technology is evolving with Semantic Web, the interaction must also evolve. With the emergence of the Semantic Web and Semantic Web services, which give information well-defined meaning and enable computer work in cooperation with humans, the interactions with Web-delivered information has become possible and thus the complexity of the human communication interface has increased. For example, instead of being an information receiver only, user can interact with information to construct new information and build knowledge. In addition, with the user terminal getting smaller and smaller in size like PDA, Pocket PC, together with the service being more customized to the user's personal need and preference, the human interface design becomes even more challenging than ever.

In ubiquitous mobile communication environment, human computing interfaces form one of the major contextual information of the user as well as one of the major component in the delivery path. Therefore, it is essential to bring interaction design principles with other contextual information into the semantically structured information in order to facilitate this evolution of the Web. On the other hand, with the popularity of Semantic Web and wide acceptance of its technology in integrating knowledge from various heterogeneous parties, embedding Semantic Web technology into the HCI design is envisioned to be a necessity for automating the deployment of rich user interfaces.

Lower Layer of Mobile Communication

One of the important contextual information to be included, and maybe semantically described, when customizing Semantic Web content and service to the user ubiquitously are the network conditions in the delivery path, e.g. bandwidth, QoS, Security, latency, jitter etc. Signalling and/or information exchange is required between the application layer and the underlying network layers for request and response. Enhancements to the communication protocols with semantic capabilities are envisaged to be required in order to assure user's satisfaction in ubiquitous service delivery. In addition, there have been extensive efforts to tackle the network layer integration of QoS, security and mobility management over heterogeneous network in a mobile environment.

Autonomous Computing

The vision of autonomous computing is to enable computing system operate in a fully autonomous manner. The challenges of autonomous computing are robustness, simplicity for the end-user and seamless integration (Hercock, 2002). With the vision of being a global information integrator by making information computer-interpretable, Semantic Web technologies can help realizing the vision of autonomous computing, particularly in a ubiquitous mobile communication environment where constant changes take place and autonomous process are expected.

Grid, Semantic Grid

Grid development is targeted at the problem of efficiently using computing power of distributed resources for achieving a common set of tasks.

Typical Grid toolkits include GLOBUS[17]. Semantic Grid is oriented towards enhancing typical Grid services or processes with ontology-based descriptions (Goble et al., 2004). Different types of Grid resources can be used by ontology–enabled mobile services to reach their goals.

ONTOLOGY FRAMEWORK STUDIES

In this section, we describe ongoing research and development combining the areas of ubiquitous mobile communication and Semantic Web. One can view convergence of Semantic technologies with mobile communication from two sides: inclusion of the Semantic technologies in solutions delivered by mobile communication project from one side; and mobile communication use cases in core Semantic technology projects from the other side. On the one hand, work on development of mobile communication applications, enablers and services with involvement of ontologies has been carried out in the following mobile communication projects: SPICE[18], MobileVCE[19], Mobilife[20], OPUCE[21], Ambient Networks[22], etc. On the other hand, research and development involving mobile aspects has been carried out in the following Semantic Web projects: TripCom[23], SWING[24], ASG[25], SmartWeb: Mobile Access to the Semantic Web[26], etc. In this section, we provide detailed illustrating examples of the ontology work carried out for mobile communication solutions, specifically, mobile ontology (SPICE project) and an ontology solution for multimedia (MobileVCE project).

Mobile Ontology

Mobile environments and the Web converge forming a shared Distributed Communication Sphere (DCS). This causes the appearance of new settings to be supported, e.g., when the user utilizes mobile and fixed devices to interact with systems. Interaction and connectivity of mobile applications with the Internet increase. To ensure interoperation of mobile and Web services, applications and tools (running on heterogeneous various service platforms in such a sphere), developers need to have a shared specification of objects belonging to the sphere and their roles. Certain ontologies have already been developed for the mobile communication domain by employing area with employment of Semantic Web formalisms (Korpipää et al., 2004; Pfoser et al., 2002). However, widespread and global adoption of such ontologies remains a challenge.

Approaching the problem of interoperation between the Web and mobile service technologies, Mobile ontology, a comprehensive "higher-level" ontology for mobile communication domain, is being developed. Currently, definition and implementation of the Mobile ontology is managed as a collaborative effort amongst participants of the EU IST SPICE Integrated Project.

Mobile Ontology Introduction

What's Mobile Ontology for?

Mobile Ontology is being developed as a comprehensive "higher-level" ontology for mobile communication domain. The ontology is a machine readable schema intended for sharing knowledge and exchanging information both across people and across services/applications, and it covers domains related to mobile communications, specifically, addressing persons, terminals, services, networks.The added values of Mobile Ontology are:

- Providing an easy and formal way to reference objects from the mobile communication domain (in particular, to serve as an exchange format between mobile service enablers).
- Providing an opportunity to implement enhanced, ontology-based reasoning.
- Providing a formal representation of the

domain to be used in research and development projects, and for educational purposes.

Mobile Ontology Overview

DCS-related vocabulary terms, grouped in broad categories, are presented in Figure 1.

Mobile Ontology, in particular, its DCS Vocabulary (Zhdanova et al., 2006) definitions are written using RDF and OWL (Manola & Miller, 2004; Dean & Schreiber, 2006) that makes it easy for software (both Web-based and mobile-oriented) to process facts about the terms in the DCS vocabulary, and consequently about the things described in DCS documents. A DCS document/instance data can be combined with other DCS documents to create unified sources of information.

Example

A very basic annotation describing the state of the communication model is:

```
<?xml version=”1.0”?>
<rdf:RDF
xmlns:rdf=”http://www.
w3.org/1999/02/22-rdf-syntax-
ns#”
xmlns:xsd=”http://www.
w3.org/2001/XMLSchema#”
xmlns:rdfs=”http://www.

rdf:datatype=”http://www.
w3.org/2001/XMLSchema#string”
></rdfs:comment>
</Person>
</belongsTo>
</Device>
…
</rdf:RDF>
```

RDF/S and OWL have been chosen as formats to represent the mobile ontology, as they are current recommendation ontology languages of W3C and have a relatively large tool support for implementation of enablers and applications.

Starting from the DCS ontology, the Mobile ontology has developed a new structure and evolved in Mobile ontology Core and Mobile subontologies. Mobile ontology Core comprises the telecommunications domain concepts and properties that occur most commonly and in various subdomains or application types. Mobile subontologies contain further details related to specific topics in telecommunications, and its items are linked to the items of the Mobile ontology Core. The Mobile ontology Core overview is depicted at Figure 2.

Currently the subontologies on the following topics are being represented in the Mobile ontology infrastructure: Profile, Service, Service Context, DCS, Service Roaming, Rules and recommendations, Presence, Location, and Content. The up-to-date ontology versions and the status of the work are represented at the Mobile Ontology website[27].

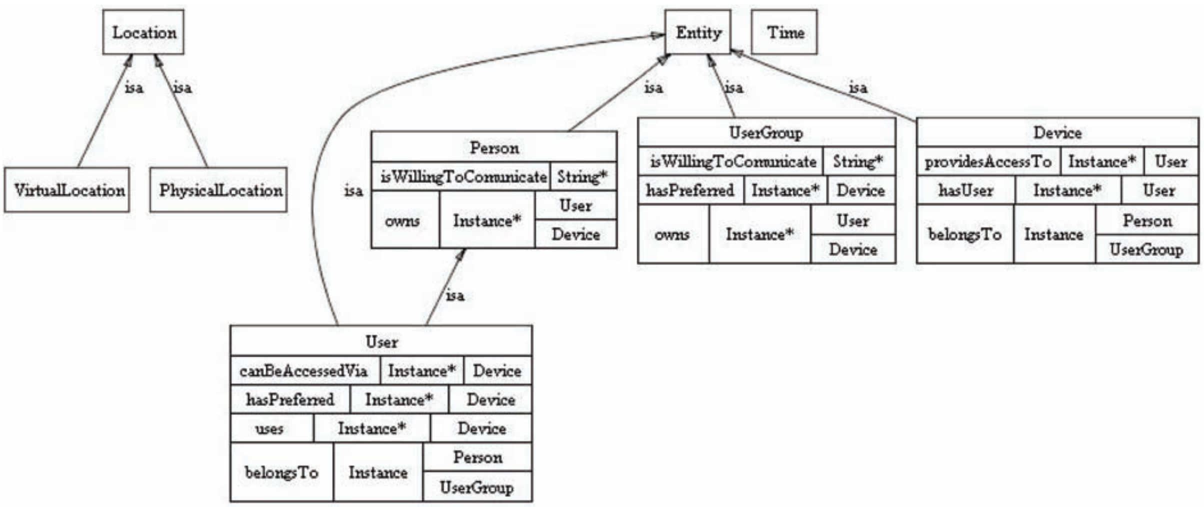
Reuse of Schemata and Ontologies

Certain schemata covering the domains of the Mobile ontology exist and have already acquired significant communities. Such schemata can be either an output of the standardization bodies or coming in a "bottom-up" manner from companies and individuals and being widely accepted by the

Figure 2. Mobile ontology core visualization



masses. These schemata and ontologies can be specified in different knowledge representation formalisms. We address external sources represented via the most popular formats, namely OWL, RDF/S and XML/S.

Relating and mapping these schemata to the Mobile ontology is mainly beneficial for interoperation of the Mobile ontology community with other mobile communities. Thus:

- Mobile ontology developers and users benefit acquiring additional knowledge in the mobile communication domain captured in the existing OWL, RDF, XML schemas (i.e., reusing the present knowledge).
- Users of the related ontologies and schemas benefit from a straightforward mapping of their schemas to the Mobile ontology that enables a simpler move to/involvement or extension of the Semantic technologies for these communities.

Technically, two different approaches to combine the Mobile ontology with the existing common ontologies and schemata will be considered, depending on whether the data is encoded via an ontology language (such as PDF/S and OWL) or only via XML.

Approach 1: RDF/S or OWL Encoding

The following principles are valid when considering integration of Mobile ontology with ontologies of relevant topics expressed via RDF/S or OWL formalisms:

- When necessary directly reusing the agreed ontologies or their parts when modelling processes;
- Establishing and using the library of mappings of these ontologies with the "higher" level Mobile ontology classes and properties that have similar items as the used external ontology. Such a mapping library would not be re-modelling, but stating relations between items in a machine readable format. Equivalence, for example, can be stated using constructions "owl:sameAs" so that applications and enablers can "understand" that an item from the Mobile ontology and an "imported" agreed upon ontology are the same.

The RDFS and OWL-based standard schemata considered for this approach are listed in Table 2.

Approach 2: XML Encoding

The following principles are valid when considering integration of Mobile ontology with schemata of relevant topics expressed via XML formalisms:

- Re-modelling XML schemata in OWL and providing the new sub-ontologies as relatively independent ontology submodules under the umbrella of the Mobile ontology;
- Creation of the converters lifting up the instance data represented solely in the XML format to RDF.

So the ontology work with the existing XML schemas would focus on ontologizing/considering the knowledge present these schemas, and combining it with the Mobile ontology, and not extending these schemata.

The XML-based standard schemata considered for this approach are listed in Table 3.The following goals addressed by Mobile Ontology are open challenges for the current state of the art:

- The first comprehensive higher level ontology for mobile communication domain that is constructed with involvement/support of major players in mobile communication area, i.e. the ontology (i) responds to the needs of mobile service developers, (ii) is evolving, (iii) representatively captures the domain in an unbiased fashion.
- The most large scale international investigation on the use of Semantic technology

in mobile communication domain.

Collaboration Aspects

Mobile Ontology construction has been initially implemented within two major deliverables of SPICE EU project. 25 persons from 10 industry and research organizations stemming from 6 European countries have been initially involved in this specific cross issue. Therefore, apart from the definition of the up-to-date ontology infrastructure for Mobile services, the results of this study include observation of collaboration aspects of developers and users in the ontology construction.

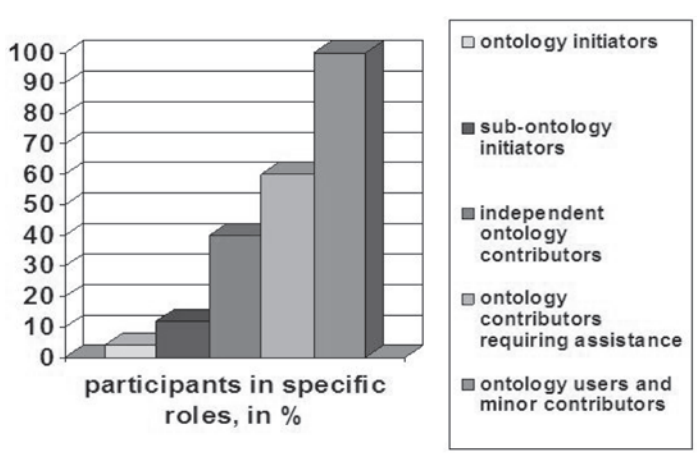
Here we show how involved parties collaborated on the ontology construction, and what personal involvement expectations for a larger scale ontology infrastructure would be. In Figure 3, the extent to which the developers have been typically involved in initial definition of the ontology is demonstrated. The figure shows that most contributors tend to provide minor extensions to the ontology or choose a role of the user, which also confirms the previous research (Zhdanova, 2006).Summarising, the main challenges identified in collaborative ontology construction as they have been observed are as follows:

- **Educational:** People with no/little knowledge on ontologies require *at least an introduction to the field*.
- **Methodology:** As of yet *no widely accepted or best practice solutions* on how to acquire ontologies from people in such a setting.
- **Basic technology:** Current ontology language standards (such as OWL) cause *confusion and awkward modelling solutions*.
- **Tool support:***Better tools for ontology construction process coordination, documentation* would help to avoid ad-hoc solutions and manual work.

Ontology-Based Multimedia

Nowadays, network access technologies, such as Bluetooth, WiFi, WiMAX, are bringing the dream of ubiquitous service provision closer to reality. Ubiquitous service provision is of interest to service providers, telecommunication operators and technology manufactures for their future revenue prospect. However, the barriers to the delivery of ubiquitous services arise from the desire to deliver a wide service mix to users having a wide range of access devices via a multitude of heterogeneous access networks with different preferences and likings. Most of the existing applications and services are created and provided

Figure 3. Collaboration patterns in mobile ontology construction



assuming a traditional pre-set delivery method and homogeneous transport media, which indicates a great importance and necessity for content and service adaptation in order to deliver them in such a ubiquitous environment. Such adaptation must be 'context-aware' and must facilitate user and situation specific content and service provision.

Therefore, the information from all the parties involved in the content and service delivery chain will form a contextual knowledge base that is shared by different operational agents in order to come up with a delivery or adaptation decision autonomously. These agents are generally heterogeneous in nature and distributed across networks. How to describe and represent such a knowledge base is fundamental to the development of a content and service adaptation framework which supports ubiquitous service delivery. This work has formed part of the Ubiquitous Services Core Research Programme of the Virtual Centre of Excellence in Mobile & Personal Communications, Mobile VCE.

Ontology has been recognized as the knowledge representation scheme and OWL as the knowledge representation language. However, to define a set of commonly-agreed vocabularies for the adaptation domain remains as a challenging issue. The ubiquitous content/service adaptation domain involves multiple sub-domains, i.e. the user domain, the content/service domain and the adaptation operation domain. Many efforts have been seen in recent years aiming to reach a description standard including vocabularies in order to achieve maximum acceptance and interoperability among communities. So far, the widely-acknowledged standards include usage environment description standards describing user information, device and network characteristics etc., such as CC/PP, UAProf and MPEG-21, and content description standards such as MPEG-7. Among those, MPEG-7 (ISO/IEC JTC1/SC29/WG11 N3752, 2000) and MPEG-21 DIA (ISO/IEC 21000-7, 2004) provide a good combination to linking content description with user environment description besides their well-established comprehensiveness in describing the respective domains. MPEG-7 offers several tools, i.e. Description Schemes (DS), to annotate multimedia content at different levels. These include Description Definition Language (DDL), Visual Schemes, Audio Schemes and Multimedia Description Schemes etc. MPEG-21 provides tools to describe the environment to enable transparent multimedia creation, delivery and consumption between heterogeneous environments. The most relevant part within MPEG-21 standard for the adaptation domain is Digital Item Adaptation (DIA). It provides tools to describe the user environment including: user characteristics, such as user info, preferences, usage history and physical characteristics, Device characteristics, such as display, memory and battery, Network characteristics, such as error characteristics and bandwidth, and Natural Environment characteristics such as noise and illumination.

Recent research efforts have reflected the recognition of using MPEG-7 and MPEG-21 DIA, together with ontology-based technologies, to construct an ontology to support the content/service adaptation (Soetens et al., 2004; Jannach et al., 2006). Though OWL has been chosen as the description language, Soetens et al. adopted limited usage of MPEG-21 vocabularies due to the immaturity of this standard at the time of writing (Soetens et al., 2004). In (Jannach et al., 2006), though MPEG vocabularies are adopted to form the domain ontology, the representation remains its original format of XML. With the actual adaptation operations being described in OWL-based language, this work realizes the integration of the different representation formats on the technical level using XML-based and logic-based technologies. Therefore, although MPEG-7 and MPEG-21 standards have been acknowledged for their strengths in multimedia domain description and delivery, their strengths can be still greatly enhanced by adding machine-processable semantics via ontology representation languages, such as OWL and RDF(S).

There exist several efforts to construct ontology representations of MPEG-7 and MPEG-21 (Hunter, 2001; Garcia, 2005). Those efforts construct ontology automatically by means of XSLT transformation according to the rules specified in (Garcia, 2005). By automatically converting the XML tree structure, the obtained ontology describes the relationship between the types of the tree element instead of describing the relationships between the semantics embodied by the tree elements. Although this approach expresses the XML-based standards in an OWL or RDF format, it does not add much semantic expressiveness to them. Such approach would be applied in any automatic XML schema to OWL conversion regardless of the semantics of the respective domain. In (Li et al., 2007), it argues that, for an expressive OWL representation of the XML-based standards, manual conversion is necessary. The manual conversion may result in some XML elements being discarded or treated with another XML construct as one OWL concept as a consequence of its semantic interpretation. There are no rules on how to manually convert an XML schema description into OWL ontology. Different from automatic conversion, which merely translates the XML syntax to OWL syntax, manual conversion has to examine the elements and the attributes of the XML schema, study their semantics, and translate them into OWL constructs.

CONCLUSION

State of the art and trends in convergence of the Semantic Web and mobile communication fields are presented in this article. Knowledge representation formalisms, relevant research fields, relevant ontologies are detailed, and the challenges of Semantic technology application to the mobile communications have been discussed. State-of-the-art examples of the work in this area have been outlined, including the development and use of ontology infrastructures that can serve as a semantic basis for applications and enablers within the convergence of the mobile and the Web worlds.

In a nutshell, one may conclude that (i) there exist a large number of ontologies addressing context-awareness and mobile communication issues, (ii) these ontologies are difficult to find and they are not or weakly linked and connected to each other. Factually, most of the time they do not form Semantic Web as the Web is about linking the data (and the users thus obtaining the typical Semantic Web benefits, such as interoperability), which is not the case for the current Semantic Mobile Communications.

FUTURE RESEARCH DIRECTIONS

The questions for the further research and development include: How to make these ontologies collaboratively constructed, linked to each other, easily found, used and evolved? And more specific, follow-up questions thus are:

1. How to involve developers and users in community-driven ontology construction and to what extent one should expect their involvement?
2. Which technical infrastructure is needed to implement this vision?

Ontologies are evolving as the domain is evolving and capturing the whole domain and all the needs by a (small) group of ontology developers alone is ineffective (Zhdanova, 2006). The ontology infrastructure for ubiquitous mobile communications should provide a user-friendly support to the ontology-based context-aware application and service developer with the following methods:

1. Key-word based ontology search (e.g., similar to OntoSelect[28], Swoogle[29])

2. Extraction and segmentation of the required ontology parts (e.g., operated on a level of triples and eventually on demand arranged in a stand-alone schemata)
3. In case no existing relevant ontology parts are found in the ontology platform infrastructure, possibility to plug in freshly developed ontologies and extensions
4. Simple ontology instantiation, with a subsequent simple discovery and use of the instance data
5. Ontology matching and alignment to the existing ontologies in case of duplicated modeling discovery, e.g., in a community-driven manner (Zhdanova & Shvaiko, 2006)
6. Search of relevant data within the instances (e.g., employing technologies such as YARS (Harth et al., 2006)
7. In case the developer made new ontology design/extensions, allow him/her easily plugging in the evolved versions of his/her ontologies/extensions, keeping up with the agreed ontology versioning practices

In conclusion, the starting points for the integration of the fields of Semantic Web and ubiquitous mobile communications exist both on the ontology schemata level as well as on the tools level. However, practices and processes for the common usage of the technologies originating from these two fields are still to be acquired. It is expected, that the new practices and processes are also to influence the future development of applications, services and tools appearing in the unified field.

Chapter 1.5
A Review of Fuzzy Models for the Semantic Web

ABSTRACT

In the Semantic Web context, information would be retrieved, processed, shared, reused and aligned in the maximum automatic way possible. Our experience with such applications in the Semantic Web has shown that these are rarely a matter of true or false but rather procedures that require degrees of relatedness, similarity, or ranking. Apart from the wealth of applications that are inherently imprecise, information itself is many times imprecise or vague. In order to be able to represent and reason with such type of information in the Semantic Web, different general approaches for extending semantic web languages with the ability to represent imprecision and uncertainty has been explored. In this chapter, we focus our attention on fuzzy extension approaches which are based on fuzzy set theory. We review the existing proposals for extending the theoretical counterpart of the semantic web languages, description logics (DLs), and the languages themselves. The following statements will include the expressive power of the fuzzy DLs formalism and its syntax and semantic, knowledge base, the decidability of the tableaux algorithm and its computational complexity etc. Also the fuzzy extension to OWL is discussed in this chapter.

DOI: 10.4018/978-1-60566-028-8.ch002

INTRODUCTION

The Semantic Web is an extension of the current web in which the web information can be given well-defined semantic meaning, and thus enabling better cooperation between computers and people. From this point of view, we should find some methods which can describe the semantic meaning of the web. Fortunately, "ontology" can do this. The core of the Semantic Web is "ontology" which refers to a set of vocabulary to describe the conceptualization of a particular domain. Over the past few years, several ontology definition languages for the Semantic Web have emerged, including RDF(S), OIL, DAML, DAML+OIL, and OWL. Among them, OWL is the newly released standard recommended by W3C. As the Semantic Web expects, OWL has the reasoning nature because description logics (*DL*s) (Baader, 2003) are essentially the theoretical counterpart of OWL and play a crucial role in this context. *DL*s provide a logical reconstruction of object-centric and frame-based knowledge representation languages. It is a subset of first-order logic that provides sound and decidable reasoning support (Baader, 2003).

It is clear that *DL*s play a key role in the Semantic Web. As with traditional crisp logic, any sentence in OWL, being asserted facts, domain knowledge, or reasoning results, must be either true or false and nothing in between. However, most real world domains contain uncertainty knowledge and incomplete or imprecise information that is true only to a certain degree. Ontologies defined by these languages thus cannot quantify the degree of the overlap or inclusion between two concepts, and cannot support reasoning in which only partial information about a concept or individual in the domain can be obtained. Uncertainty becomes more prevalent when more than on ontologies are involved where it is often the case that a concept defined in on ontology can only find partial matches to one or more concepts in another ontology. To overcome the difficulty arising from the crisp logics, existing ontology languages need to be extended to be able to capture uncertainty knowledge about the concepts, properties and instances in the domain and to support reasoning with partial, imprecise information. Along this direction, researchers in the past have attempted to apply different formalisms such as Fuzzy logic (Zadeh, 1965), Rough set theory and Bayesian probability as well as ad hoc heuristics into ontology definition and reasoning.

In this paper, we review existing proposals to extend semantic web languages with the capability to handle uncertain information to better deal with the situations mentioned above. There are many ways of representing and dealing with uncertainty. In this paper, we restrict our attention to approaches that use fuzzy methods for representing uncertain information. In particular, we will not cover recent proposals for probabilistic extensions of semantic web languages. We will also not discuss non-monotonic and non-standard logics for representing uncertainty. As described above, existing Semantic Web languages are mainly based on logic and do not support representing imprecise and uncertain information. In this paper, we therefore review a number of proposals for extending logical languages with fuzzy extensions in more details. We focused on:

1. Approaches that extend description logics which play as the theoretical counterpart of the semantic web languages.
2. Approaches that directly extend semantic web languages, in particular OWL.

In the first category, we cover fuzzy extensions of description logics which are commonly accepted as being the formal basis of OWL. Even though most approaches only cover logics that are much weaker than OWL, the methods proposed can directly be applied to the corresponding subset of OWL without changes because the description logics play as the theory counterpart of the OWL. When talking about the different approaches, we will survey them according to the expressive power from weaker to stronger. And in the following survey, we should discuss the following issues of the different approaches:

- Expressiveness of the logical language
- The syntax and semantic of the fuzzy extension to description logics

- The components of the knowledge base
- Tableaux algorithm for the description logics
- The decidability and complexity of the tableaux algorithm

Indeed, the balance of expressive power and the computability of the fuzzy extension of description logics is a hot topic of the research. Generally speaking, the more expressive of the description logic, the higher computational complexity of it, so we should consider the balance of the two factors in a real application. At last, in the latter category, we also review a number of proposals for extending the ontology description language OWL.

The paper is structured as follows. We first present some background information on semantic web languages and related formalisms that are the basis for the logical languages used in the different approaches discussed later in the paper. We also provide a brief introduction to fuzzy set theory which the fuzzy description logics are based on. In the mainly part of this chapter, we survey the different approaches to extend the description logics to represent the imprecise and uncertainty information according their expressive power. We also discuss proposals for fuzzy languages OWL for the semantic web. Finally, we conclude with a critical review of the state of the art and an analysis of directions for future research.

PRELIMINARIES AND BACKGROUND

Description Logics

In the last decade a substantial amount of work has been carried out in the context of Description Logics. *DL*s are a logical reconstruction of the so-called frame-based knowledge representation languages, with the aim of providing a simple well-established Tarski-style declarative semantics to capture the meaning of the most popular features of structured representation of knowledge. Nowadays, *DL*s have gained even more popularity due to their application in the context of the Semantic Web (Berners-Lee, 2001).The recent research about description logics can be divided into three categories:

- Introducing the theoretical foundations of description logics, addressing some of the most recent developments in theoretical research in the area;
- Focusing on the implementation of knowledge representation systems based on Descriptions Logics, describing the basic functionality of a *DL* system, surveying the most influential knowledge representation systems based on descriptions, and addressing specialized implementation techniques;
- Addressing the use of description logics and of *DL*-based systems in the design of several applications of practical interest.

In the following statements, we mainly focus on the first category, especially the theoretical formalism of the description logics, with respect to the balance between its expressive power and its computational complexity. Indeed, subsequent results on the tradeoff between the expressiveness of a *DL* language and the complexity of reasoning with it, and more generally, the identification of the sources of complexity in *DL* systems, showed that a careful selection of language constructs was needed and that the reasoning services provided by the system are deeply influenced by the set of constructs provided to the user. We can thus characterize three different approaches to the implementation of reasoning services. The first can be referred to as *limited + complete*, and includes systems that are designed by restricting the set of constructs in such a way that subsumption would be computed efficiently, possibly in polynomial time. The second approach can be denoted as *expressive*

+ *incomplete*, since the idea is to provide both an expressive language and efficient reasoning. The drawback is, however, that reasoning algorithms turn out to be incomplete in these systems. After some of the sources of incompleteness were discovered, often by identifying the constructs—or, more precisely, combinations of constructs—that would require an exponential algorithm to preserve the completeness of reasoning, systems with complete reasoning algorithms were designed. Systems of this sort are therefore characterized as *expressive + complete*; they were not as efficient as those following the other approaches, but they provided a test bed for the implementation of reasoning techniques developed in the theoretical investigations, and they played an important role in stimulating comparison and benchmarking with other systems.

Now, we survey the languages of the description logics according to their expressive power with the beginning of *AL*. Elementary descriptions are atomic concepts and atomic roles (also called concept names and role names). Complex descriptions can be built from them inductively with concept constructors and role constructors. In abstract notation, we use the letters *A* and *B* for atomic concepts, the letter *R* for atomic roles, and the letters *C* and *D* for concept descriptions. Description languages are distinguished by the constructors they provide. In the sequel we shall discuss various languages from the family of *AL*-languages. The language *AL* (= attributive language) has been introduced as a minimal language that is of practical interest. The other languages of this family are extensions of *AL*.

The Basic Description Logic *AL*

Concept descriptions in *AL* are formed according to the following syntax rule:

$C, D ::= \top$ | (universal concept)

$\bot$ | (bottom concept)

A | (atomic concept)

$C \sqcap D$ | (intersection)

$\forall R . C$ (value restriction)

$\exists R . \bot$ | (limited existential quantification)

In *AL*, negation can only be applied to atomic concepts, and only the top concept is allowed in the scope of an existential quantification over a role. In order to define a formal semantics of *AL*-concepts, we consider interpretations I that consist of a non-empty set Δ^I (the domain of the interpretation) and an interpretation function $\bullet^I$, which assigns to every atomic concept A a set $A^I \subseteq \Delta^I$ and to every atomic role R a binary relation $R^I \subseteq \Delta^I \times \Delta^I$. The interpretation function is extended to concept descriptions by the following inductive definitions:

$\top^I = \Delta^I$

$\bot^I = \Phi$

$(\neg A)^I = \Delta^I \setminus A^I$

$(C \sqcap D)^I = C^I \cap D^I$

$(\forall R . C)^I = \{a \in \Delta^I \mid \forall b. (a, b) \in R^I \rightarrow b \in C^I\}$

$(\exists R . \bot)^I = \{a \in \Delta^I \mid \exists b. (a, b) \in R^I\}$

We say that two concepts C, D are equivalent, and write $C \equiv D$, if $C^I = D^I$ for all interpretations I.

The Family of *AL*-languages

We obtain more expressive languages if we add further constructors to *AL*. The *union* of concepts (indicated by the letter U) is written as $C \sqcup D$, and interpreted as

$(C \sqcup D)^I = C^I \cup D^I$:

Full existential quantification (indicated by the letter E) is written as $\exists R.C$, and interpreted as

$$(\exists R.C)^I = \{a \in \Delta^I \mid \exists b.\ (a, b) \in R^I \wedge b \in C^I\}$$

Note that $\exists R.C$ differs from $\exists R.$ in that arbitrary concepts are allowed to occur in the scope of the existential quantifier.

Number restrictions (indicated by the letter N) are written as $\geq nR$ (at-least restriction) and as $\leq nR$ (at-most restriction), where n ranges over the nonnegative integers. They are interpreted as

$$(\geq nR)^I = \{a \in \Delta^I \mid |\{b \mid (a, b) \in R^I\}| \geq n\}$$

and

$$(\leq nR)^I = \{a \in \Delta^I \mid |\{b \mid (a, b) \in R^I\}| \leq n\}$$

respectively, where "|•|" denotes the cardinality of a set. From a semantic view point, the coding of numbers in number restrictions is immaterial. However, for the complexity analysis of inferences it can matter whether a number n is represented in binary (or decimal) notation or by a string of length n, since binary (decimal) notation allows for a more compact representation.

The *negation* of arbitrary concepts (indicated by the letter *C*, for "complement") is written as $\neg C$, and interpreted as

$$(\neg C)^I = \Delta^I \setminus C^I$$

Extending *AL* by any subset of the above constructors yields a particular *AL*-language. We name each *AL*-language by a string of the form

AL[U][E][N][C];

where a letter in the name stands for the presence of the corresponding constructor. For instance, *ALEN* is the extension of *AL* by full existential quantification and number restrictions.

The More Expressive Description Logics

There are several possibilities for extending *AL* in order to obtain a more expressive *DL*. The three most prominent are adding additional concept constructors, adding role constructors, and formulating restrictions on role interpretations. Below, we start with the third possibility, since we need to refer to restrictions on roles when defining certain concept constructors. For these extensions, we also introduce a naming scheme. Basically, each extension is assigned a letter or symbol. For concept constructors, the letters/symbols are written after the starting *AL*, for role constructors, we write the letters/symbols as superscripts, and for restrictions on the interpretation of roles as subscripts. As an example, the *DL* $ALCQ^{-1}_{R+}$, extends *AL* with the concept constructors negation (*C*) and qualified number restrictions (*Q*), the role constructor inverse ($^{-1}$), and the restriction that some roles are transitive($_{R+}$).

Restrictions on role interpretations These restrictions enforce the interpretations of roles to satisfy certain properties, such as functionality and transitivity. We consider these two prominent examples in more detail. Others would be symmetry or connections between different roles.

(i) *Functional roles*. Here one considers a subset N_F of the set of role names N_R, whose elements are called *features*. An interpretation must map features *f* to functional binary relations $f^I \subseteq \Delta^I \times \Delta^I$. *AL* extended with features is denoted by AL_f.

(ii) *Transitive roles*. Here one considers a subset N_{R+} of N_R. Role names $R \in N_{R+}$ are called *transitive roles*. An interpretation must map transitive roles $R \in N_{R+}$ to transitive binary relations $R^{I} \subseteq \Delta^{I} \times \Delta^{I}$. *AL* extended with transitive roles is denoted by AL_{R+}.

All the *DL*s mentioned until now contain the concept constructors intersection and value restriction as a common core. *DL*s that allow for intersection of concepts and existential quantification (but not value restriction) are collected in the *EL*-family. The only constructors available in *EL* are intersection of concepts and existential quantification. Extensions of *EL* are again obtained by adding appropriate letters/symbols. In order to avoid very long names for expressive *DL*s, the abbreviation *S* was introduced for ALC_{R+}, i.e., the *DL* that extends *ALC* by transitive roles. Prominent members of the *S*-family are *SIN* (which extends ALC_{R+} with number restrictions and inverse roles), *SHIF* (which extends ALC_{R+} with role hierarchies, inverse roles, and number restrictions of the form $\leq 1R$), and *SHIQ* (which extends ALC_{R+} with role hierarchies, inverse roles, and qualified number restrictions). Actually, the *DL*s *SIN*, *SHIF*, and *SHIQ* are somewhat less expressive than indicated by their name since the use of roles in number restrictions is restricted: roles that have a transitive sub-role must not occur in number restrictions.

Description Logics with Data Type Representation

A drawback that all *DL*s introduced until now share is that all the knowledge must be represented on the abstract logical level. In many applications, one would like to be able to refer to concrete domains and predefined predicates on these domains when defining concepts. To solve the problem, Baader and Hanschke prompt two extensions (Hanschke, 1992; Haarslev et al., 1999). In the two papers, the definition of *concrete domain* is given and a tableau-based algorithm for deciding consistency of *ALC*(*D*)-ABoxes for admissible *D* was introduced in (Baader & Hanschke, 1991). The algorithm has an additional rule that treats existential predicate restrictions according to their semantics. The main new feature is that, in addition to the usual "abstract" clashes, there may be concrete ones, i.e., one must test whether the given combination of concrete predicate assertions is non-contradictory. This is the reason why we must require that the satisfiability problem for *D* is decidable. As described in (Baader and Hanschke, 1991), the algorithm is not in PSpace. Using techniques similar to the ones employed for *ALC* it can be shown, however, that the algorithm can be modified such that it needs only polynomial space (Lutz, 1999), provided that the satisfiability procedure for *D* is in PSpace. In the presence of acyclic TBoxes, reasoning in *ALC*(*D*) may become NExpTime-hard even for rather simple concrete domains with a polynomial satisfiability problem (Lutz, 2001).

The more expressive description logics *SHOQ*(*D*) which can represent data information is proposed in (Horrocks, 2001). Although *SHOQ*(*D*) is rather expressive, it has a very serious limitation on data types; i.e., it does not support customised data types. It has been pointed out that many potential users will not adopt it unless this limitation is overcome. Pan and Horrocks release a series of papers about data types to solve the problem, in (Pan & Horrocks, 2006; Pan, 2007). In the two papers, they summarize the limitations of OWL datatyping and propose the data type approach. For example, the *SHIQ*(*G*) and *SHOQ*(*G*) *DL*s presented in (Pan & Horrocks, 2006; Pan, 2007) can support user-defined data type and user-defined data type predicates.

Fuzzy Set Theory

Fuzzy data is originally described as fuzzy set (Zadeh, 1965). Let *U* be a universe of discourse, then a fuzzy value on *U* is characterized by a fuzzy set *F* in *U*. A membership function $\mu_F: U \rightarrow [0, 1]$ is defined for the fuzzy set *F*, where $\mu_F(u)$, for each $u \in U$, denotes the degree of membership of *u* in the fuzzy set *F*. Thus the fuzzy set *F* is described as follows.

$F = \{\mu_F(u_1)/u_1, \mu_F(u_2)/u_2, ..., \mu_F(u_n)/u_n\}$

When the $\mu_F(u)$ above is explained to be a measure of the possibility that a variable *X* has the value *u* in this approach, where *X* takes values in *U*, a fuzzy value is described by a possibility distribution π_X. Let π_X and *F* be the possibility distribution representation and the fuzzy set representation for a fuzzy value, respectively. In the fuzzy set theory, each object $u_i \in U$ is assigned a single value between 0 and 1, called the degree of membership, where *U* is a universe of discourse.

Fuzzy set theory is the theory basis for fuzzy extensions to description logics to represent imprecise and uncertain information.

FUZZY EXTENSIONS OF SEMANTIC WEB LANGUAGES

Extensions of Description Logics

Much work has been carried out towards combining fuzzy logic and description logics during the last decade. The initial idea was presented by Yen in (Yen, 1991), where a structural subsumption algorithm was provided in order to perform reasoning. The following statements will illustrate all the fuzzy extensions to *DL*s from weaker to stronger in expressive power.

The Family of *FALC* Languages

ALC is the basic format of the description logics. Reasoning in fuzzy *ALC* was latter presented in (Straccia, 2001), as well as in other approaches (Straccia, 1998), where an additional concept constructor, called membership manipulator was included in the extended language. In all these approaches tableaux decision procedures were presented for performing reasoning services. The operations used to interpret the concept constructors in all these approaches were the same ones as in our context. (Tresp & Molitor, 1998) contains complete algorithms for solving these inference problems in the respective fuzzy extension of *ALC*. Although both algorithms are extensions of the usual tableau-based algorithm for ALC, they differ considerably. For example, the algorithm in (Tresp & Molitor, 1998) introduces numerical variables for the degrees, and produces a linear optimization problem, which must be solved in place of the usual clash test. In contrast, (Straccia, 2001) deals with the membership degrees within his tableau-based algorithm.

The fuzzy description logic *FALC* *Definition.* Let N_I, N_C and N_R be three disjoint sets: N_I is a set of individual names, N_C is a set of fuzzy concept names and N_R is a set of fuzzy role names. Fuzzy *ALC*-concepts are defined as

$C, D ::= \bot | \mathrm{T} | A | \neg C | C \cup D | C \cap D | \exists R.C | \forall R.C$;

Here $A \in N_C$, $R \in N_R$. Fuzzy *ALC* semantics is defined by a fuzzy interpretation $I = \langle \Delta^I, \cdot^I \rangle$, Here Δ^I is a nonempty set and $\cdot^I$ is an function which maps every $a \in N_I$ to an element $a^I \in \Delta^I$, maps every $A \in N_C$ into a function $A^I: \Delta^I \rightarrow [0, 1]$, and maps every $R \in N_R$ into a function $R^I: \Delta^I \times \Delta^I \rightarrow [0, 1]$.Furthermore, for any fuzzy *ALC*-concepts *C* and *D*, $R \in N_R$ and $x \in \Delta^I$, we have:

$\mathrm{T}^I(x) = 1;$

$\bot^I(x) = 0;$

$(\neg C)^I(x) = 1 - C^I(x);$

$(C \cap D)^I(x) = C^I(x) \wedge D^I(x);$

$(C \cup D)^I(x) = C^I(x) \vee D^I(x));$

$(\exists R.C)^I(x) = sup_{\,y \in \Delta I} \{min\,(R^I(x, y), C^I(y))\};$

$(\forall R.C)^I(x) = inf_{\,y \in \Delta I} \{max\,(1 - R^I(x, y), C^I(y))\};$

With the introduction of the fuzzy sets into the classical *ALC*, the form of the knowledge base is changed accordingly:*Definition.* A fuzzy *ALC* knowledge base is composed of a TBox and an ABox:

- A TBox is a finite set of terminology axioms of the form $C \subseteq D$. Any interpretation I satisfies $C \subseteq D$ iff for any $x \in \Delta^I$, $C^I(x) \leq D^I(x)$. I is a model of TBox T iff I satisfies all axioms in T.
- An ABox is a finite set of assertions of the form $< \alpha \bowtie n >$, Here $\bowtie \in \{>, \geq, <, \leq\}$, $n \in [0, 1]$, α (called a fuzzy assertion) is either of the form a: C or (a, b): $R(a,b \in N_I)$. Especially, in order to giving a uniform format of the ABox, we define: when n =1, the form $<\alpha \geq 1>$ is equivalent to $<\alpha = 1>$. Concretely speaking, $<a: C \geq 1>$means that a is determinately an individual of C; $<(a, b)$: $R \geq 1>$ means that (a, b) determinately has the relationship R. Any interpretation I satisfies $<a{:}C \bowtie n>$ iff $C^I(a^I) \bowtie n$ and satisfies $<(a, b)$: $R \bowtie n >$ iff $R^I(a^I, b^I) \bowtie n$. Then I is a model of ABox A iff I satisfies all assertions in A.

Reasoning algorithms for *FALC* and their proofs can be found in (Straccia, 2001). It can be seen from syntax and semantics presented above that the entailment and subsumption relationships may hold to some degree in the interval [0, 1]. Complete algorithms for reasoning in *FALC* have been presented, that is, we have devised algorithms for solving the entailment problem, the subsumption problem as well as the best truth-value bound problem. The complexity result shows that the additional expressive power has no impact from a computational complexity point of view.

The fuzzy description logic ALC_{FM} The *DL* language used was a sub-language of the basic *DL ALC*. The main idea underlying the fuzzy extensions of description logics proposed in (Tresp & Molitor, 1998) is to leave the syntax as it is, but to use fuzzy logic for defining the semantics. Thus, an interpretation now assigns fuzzy sets to concepts and roles, i.e., concept names A are interpreted by membership degree functions of the form A^I: $\Delta^I \rightarrow [0, 1]$, and role names R by membership degree functions of the form R^I: $\Delta^I \times \Delta^I \rightarrow [0, 1]$. The interpretation of the Boolean operators and the quantifiers must then be extended from {0, 1} to the interval [0, 1].

Tresp & Molitor (1998) also propose an extension of the syntax by so-called manipulators, which are unary operators that can be applied to concepts. Examples of manipulators could be "*mostly*", "*more or less*", or "*very*". For example, if *Tall* is a concept (standing for the fuzzy set of all tall persons), then *VeryTall*, which is obtained by applying the manipulator *Very* to the concept *Tall*, is a new concept (standing for the fuzzy set of all *very tall* persons). Intuitively, the manipulators modify the membership degree functions of the concepts they are applied to appropriately. In our example, the membership function for *VeryTall* should have its largest values at larger heights than the membership function for *Tall*. Formally, the semantics of manipulators is defined by a function that maps membership degree functions to membership degree functions. The manipulators considered in (Tresp & Molitor, 1998) are, however, of a very restricted form. Lets us now consider what kind of inference problems are of interest in this context. (Yen, 1991) considers crisp subsumption of fuzzy concepts, i.e., given two concepts C, D defined in the fuzzy *DL*, he is interested in the question whether $C^I(d) \leq D^I(d)$ for all fuzzy interpretations I and $d \in \Delta^I$. Thus, the subsumption relationship itself is not fuzzified. He describes a structural subsumption algorithm for a rather small fuzzy *DL*, which is almost identical to the subsumption algorithm for the corresponding classical *DL*. In contrast, (Tresp & Molitor, 1998) are interested in determining fuzzy subsumption between fuzzy concepts, i.e., given concepts C, D, they want to know to which degree C is a subset of D. In (Tresp & Molitor, 1998), also ABoxes are considered, where the ABox assertions are equipped with a degree.

Fuzzy description logics with hedges and modifiers Reasoning in fuzzy *ALC* was also presented in other approaches (Hölldobler, 2002; 2003; 2004; 2005; 2006), where an additional concept constructor, called membership manipulator was included in the extended language. In all these approaches tableaux decision procedures were presented for performing reasoning services. (Hölldobler, 2002) presents a fuzzy description logic ALC_{FH}, where primitive concepts are modified by means of hedges. ALC_{FH} is strictly more expressive than Fuzzy *ALC* defined in (Straccia, 2001). The paper shows that given a linearly ordered set of hedges primitive concepts can be modified to any desired degree by prefixing them with appropriate chains of hedges. Furthermore, it defines a decision procedure for the unsatisfiability problem in ALC_{FH}, and discusses truth bounds, expressivity as well as complexity issues.

Strictly speaking, the language defined by (Tresp & Molitor, 1998) is more expressive, as we do not consider concept modifiers. From a semantics point of view, the extension to Tresp and Molitor's language is quite straightforward. But, the cost that we have to pay for this increasing expressive power is that, from a computational complexity and algorithms point of view, things changes radically. The fuzzy extension to *ALC* can be used as a basis both for extending existing *DL* based systems and for further research. In this latter case, there are several open points. For instance, it is not clear yet how to reason both in case of fuzzy specialisation of the general form $C \sqsubseteq D$ and in the case cycles are allowed in a fuzzy KB. Another interesting topic for further research concerns the semantics of fuzzy connectives. While for a huge number of proposals given in the literature their impact from a semantics point of view is well understood, the question how they impact from a computational complexity and algorithms point of view remains still open.

According to the above statements, the family of fuzzy *ALC* description logics can be summaried in Table 1.

The More Expressive Fuzzy Description Logics

However, *FALC* offers limited expressive power of complex fuzzy information. Some discussions about reducing *FALC* into classical *ALC* and providing a tableau for *FALC* with General Concept Inclusions (GCIs) were given in (Straccia, 2004a) and (Stoilos, 2006c), respectively. In (Stoilos, 2006c), fuzzy description logics have been proposed as a language to describe structured knowledge with vague concepts. A major theoretical and computational limitation so far is the inability to deal with General Concept Inclusions (GCIs), which is an important feature of classical *DL*s. It addresses this issue and develops a calculus for fuzzy *DL*s with GCIs. (Meghini *et al*. 1998) proposed a preliminary fuzzy *DL*, which lacks reasoning algorithm, as a modeling tool for multimedia document retrieval.

In the following statements, we survey the dif-

Table 1. The family of FALC languages

Fuzzy description logics	Corresponding references	Mainly discussed issues
FALC	(Straccia, 1998; 2001)	Syntax,semantics, properties and reasoning services
ALC_{FM}	(Tresp and Molitor, 1998)	Syntax,semantics and a mothod for computing the degree of subsumption
ALC_{FH}	(Hölldobler, 2002; 2003; 2004; 2005; 2006)	Syntax,semantics and reasoning services
ALC_{FL}	(Dinh-Khac, 2006)	Syntax,semantics and reasoning services

ferent formalisms of the description logics according to the concept constructors or role restrictions that have been constraint on them.

Fuzzy description logics with number restrictions Approaches towards more expressive *DL*s, are presented in (Sánchez, D, 2004), where the *DL* is $ALCQ_F^+$. It includes fuzzy quantifiers, which is a new novel idea for fuzzy *DL*s. Unfortunately, in the approach only the semantics of the extended languages are provided and no reasoning algorithms. But in (Sánchez, D, 2006), it introduces reasoning procedures for $ALCQ_F^+$, the fuzzy description logic with extended qualified quantification. The language allows for the definition of fuzzy quantifiers of the absolute and relative kind by means of piecewise linear functions on N and Q∩[0, 1] respectively. In order to reason about instances, the semantics of quantified expressions is defined based on recently developed measures of the cardinality of fuzzy sets. A procedure is described to calculate the fuzzy satisfiability of a fuzzy assertion, which is a very important reasoning task. The procedure considers several different cases and provides direct solutions for the most frequent types of fuzzy assertions. In addition, (Sánchez, D, 2006) defined *independence* of fuzzy assertions and obtained some results that speed up the calculation of fuzzy satisfiability in some (the most common) cases.

The series of *F-SHOIQ* Because today quite a lot of multimedia systems and applications use knowledge representation formalisms to encode and reason with knowledge that exists within the multimedia documents, (Stoilos, 2005a) presents a more expressive fuzzy *DL* f_{KD}-*SI*. The goal of this direction is to narrow the semantic gab between the content of a multimedia object, as perceived by a human being, and as "viewed" by an information system. (Stoilos, 2005a) has extended the *DL* language *SI* with fuzzy set theory. The combination of transitive and inverse roles can capture knowledge about part-whole relationships and aggregated objects. Furthermore, the incorporation of fuzziness allows the users to encode and reason with vague and imprecise knowledge. Both these properties fit well into the framework of knowledge based multimedia processing where both part-whole relationships, as well as, imprecise and vague knowledge appear in applications like multimedia information retrieval and processing. In the latter of the paper, a tableau algorithm for checking the consistency of ABox is given and has been proved that it will terminates. (Stoilos, 2005b) provides an extension of the above f_{KD}-*SI* to an even more expressive *DL*, namely f_{KD}-*SHIN*. The paper has presented an extension of the very expressive description logic *SHIN* with fuzzy set theory. It shows the semantics as well as detailed reasoning algorithms for the extend languages. A fuzzy tableau for f_{KD}-*SHIN* ABoxes is shown and it proves the flowing lemma.**Lemma:***Let A be an* f_{KD}*-SHIN ABox and R a fuzzy RBox. Then*

i. when started for A and R the tableaux algorithm terminates
ii. A has a fuzzy tableau w.r.t. R if and only if the expansion rules can be applied to A and R such that they yield a complete and clash-free completion forest.

In (Stoilos, 2006b), the syntax and semantics of fuzzy *SHOIQ* were presented and the properties of the semantics of transitivity, qualified cardinality restrictions and reasoning capabilities were investigated. (Stoilos, 2006b) extends the current state-of-the-art on fuzzy extensions to Semantic Web languages by presenting the syntax and semantics of the fuzzy-*SROIQ DL* as well as the abstract, XML syntax and semantics of a fuzzy extension to OWL 1.1. Moreover, it provides reasoning support for a fuzzy version of fuzzy-*SROIQ* by extending well-known reduction techniques of fuzzy *DL*s to classical *DL*s for the additional axioms and constructors of fuzzy-*SROIQ*.

Fuzzy description logics with concrete domain The Semantic Web is expected to process knowledge information and data information in an intelligent and automatic way. But recent research has shown that the OWL DL ontology language is very limited in representing data information. Furthermore, the OWL DL can't process imprecision and uncertainty which widely exists in human knowledge and natural language. In (Straccia, 2004b), a fuzzy extension of *ALC*(*D*) (the *ALC* extended with concrete domains) was presented. The paper presents a fuzzy description logic where the representation of concept membership functions and fuzzy modifiers is allowed, together with a inference procedure based on a mixture of a tableaux and bounded mixed integer programming.

The more expressive *DL*s which can support fuzzy concrete domains is shown in (Straccia, 2005), where the language is *SHOIN*(*D*+). It is the corresponding Description Logic of the ontology description language OWL DL. It shows that the representation and reasoning capabilities of fuzzy *SHOIN*(*D*) go clearly beyond classical *SHOIN*(*D*). Interesting features are: (i) concept constructors are based on t-norm, t-conorm, negation and implication; (ii) concrete domains are fuzzy sets; (iii) fuzzy modifiers are allowed; and (iv) entailment and subsumption relationships may hold to some degree in the unit interval [0, 1]. The fuzzy concrete domain is defined as following: $(\Delta_D, \bullet^D)$ is an interpretation. $\bullet^D$ is an interpretation which assigns each concrete individual to an element in Δ_D; assigns each simple data type role $T \in \mathbf{R}_D$ to a function $T^I : \Delta^I \times \Delta_D \rightarrow [0, 1]$; assigns each n-ary predicate p to the fuzzy relation $p^D: \Delta_D^{\,n} \rightarrow [0,1]$ which means the relationship of data types $v_1,\ldots,v_n$ satisfies predicate p in a degree in [0,1]. Based on the definition of the fuzzy concrete domain, the fuzzy data information in the semantic web can be represented and reasoning.

According to the above statements, some more expressive fuzzy description logics can be summaried in Table 2.

Extensions of OWL

More recently, little work has been carried out towards combining fuzzy logic and the Semantic Web ontology. In (Stoilos, 2005c), the OWL web ontology language was extended with fuzzy set theory, which is called f-OWL, in order to capture, represent and reason with imprecise information. Based on a fuzzy extension to OWL called Fuzzy OWL, (Stoilos, 2006a) developed a reasoning platform, Fuzzy Reasoning Engine (FiRE), which lets Fuzzy OWL capture and reason about imprecise and uncertain knowledge. Several connections between Fuzzy Logic, the Semantic Web, and its components were presented in (Stoilos, 2005c).

For most recent research issues about fuzzy logic, and more generally soft computing, in the description logics, ontologies and the Semantic Web, ones can refer to (Ma, 2006), (Sanchez, 2006a; 2006b).

Table 2. Some important fuzzy description logics

	Representation of fuzzy terminologies and concepts					**Representation of fuzzy data information**

DISCUSSION AND CONCLUSIONS

In this chapter, we focus our attention on the recent research achievements on fuzzy extension approaches which are based on fuzzy set theory. We survey existing proposals for extending the theoretical counterpart of the semantic web languages, description logics (*DL*s), and the languages themselves. The above statements include the expressive power of the fuzzy *DL*s formalism and its syntax and semantic, knowledge base, the decidability of the tableaux algorithm and its computational complexity etc. Also the fuzzy extension to OWL is discussed in this chapter. After reviewing all the proposals of fuzzy extensions, we find that it is a paradox in the balance between the expressive power of the *DL* formalism and its computational complexity. It is sure that the computational complexity will become more complex with the more expressive power of the *DL* formalism.

FUTURE RESEARCH DIRECTIONS

As overall conclusion, we can summarize that until recently, research has not paid much attention to fuzzy extensions to *DL*s in the area of the Semantic Web. However, it gains more and more interest and new approaches considering imprecise and uncertainty tend to emerge. Still, many of these approaches are rather half-baked and a lot of things are missing:

Fuzzy extensions to concrete domain to support the fuzzy user-defined data type and fuzzy user-defined data type predicate. It should be pointed out that, however, the *SHIQ*(*G*) and *SHOQ*(*G*) *DL*s presented in (Pan & Horrocks, 2006; Pan, 2007) which can support the user-defined data type and user-defined data type predicate can only deal with crisp knowledge. In the real world, human knowledge and natural language have a big deal of imprecision and uncertainty, as a result, a fuzzy extension version of *DL* language which can process fuzzy data information should be developed. Especially, we should pay more attention on the fuzzy extension of user-defined data type and user-defined data type predicates.

The computational complexity of the fuzzy tableau algorithm and the optimal technologies to the fuzzy tableau algorithm. After prompting a fuzzy tableau algorithm to an expressive *DL* language, although the decidability of the algorithm is investigated, the computational complexity is still an open problem. Furthermore, the optimal technologies can be investigated which can reduce the computational complexity of the algorithm.

Fuzzy extensions to description logics based on vague sets. A single membership degree in the fuzzy sets is inaccurate to represent the imprecision in the membership degrees. As a result, based on vague sets (Gau, 1993), a fuzzy extension of description logic should be presented. Instead of a crisp degree of membership, two degrees of membership (lower and upper degrees of membership) are used in the newly proposed fuzzy description logic version. Its syntax, semantics and inference problems and tableaux also should be investigated.

Chapter 1.6
Semantic Web Adaptation

Alexander Mikroyannidis
University of Manchester, UK

Babis Theodoulidis
University of Manchester, UK

INTRODUCTION

The rate of growth in the amount of information available in the World Wide Web has not been followed by similar advances in the way this information is organized and exploited. Web adaptation seeks to address this issue by transforming the topology of a Web site to help users in their browsing tasks. In this sense, Web usage mining techniques have been employed for years to study how the Web is used in order to make Web sites more user-friendly.

The Semantic Web is an ambitious initiative aiming to transform the Web to a well-organized source of information. In particular, apart from the unstructured information of today's Web, the Semantic Web will contain machine-processable metadata organized in ontologies. This will enhance the way we search the Web and can even allow for automatic reasoning on Web data with the use of software agents. Semantic Web adaptation brings traditional Web adaptation techniques into the new era of the Semantic Web. The idea is to enable the Semantic Web to be constantly aligned to the users' preferences. In order to achieve this, Web usage mining and text mining methodologies are employed for the semi-automatic construction and evolution of Web ontologies. This usage-driven evolution of Web ontologies, in parallel with Web topologies evolution, can bring the Semantic Web closer to the users' expectations.

DOI: 10.4018/978-1-59904-845-1.ch093

BACKGROUND

Web Usage Mining

Web usage mining has a wide variety of applications. User profiles can be created for use in Web personalization. Information can also be extracted that details how a Web site can be reorganized to better facilitate users' navigation through it. In e-commerce Web sites, the results of Web usage mining can be used to improve sales. Analyzing user access patterns can also help when targeting advertisements to specific groups of users.

Srivastava, Cooley, Deshpande, and Tan (2000) divide Web usage mining into three stages:

i. Preprocessing
ii. Pattern discovery
iii. Pattern analysis

Preprocessing consists of converting the usage, content, and structure information contained in the various available data sources into the data abstractions necessary for pattern discovery. Usage preprocessing involves the identification of users and their visiting sessions. In order for this to be accomplished, several difficulties need to be overcome. For example, proxy servers hide the actual IP addresses of the machines that are using them, thus making user identification problematic. A user that uses more than one browser, even on the same machine, will appear as multiple users. Tracking repeat visitors can also be complex if a user uses different machines.

Content preprocessing consists of converting the text, image, scripts, or multimedia files into forms that are useful for the Web usage mining process. This often involves the application of content mining techniques, such as classification or clustering. For instance, a classification algorithm could be used to limit the discovered patterns to those that contain page views about a certain subject. Similar to the preprocessing of the site's content, structure preprocessing regards the extraction of the site's structure for use in the mining procedure. The hyperlinks of each Web page build the structure of the Web site. Most Web sites have nowadays an utterly dynamic topology, thus presenting a different structure to different users. This characteristic should be considered during the structure preprocessing phase.

The preprocessing stage is followed by the discovery of traversal patterns from the user access data. Traversal patterns reveal the way a user navigates through the site during each session. Clusters of users can be discovered through clustering of similar traversal patterns. Moreover, association rules can be applied to the pages accessed during a session, independent of their ordering. Examples of association rules that were extracted from an IBM analysis of the Web logs of the Official 1996 Olympics Web site (Elo-Dean & Viveros, 1997) are:

- 45% of the visitors who accessed a page about Indoor Volleyball also accessed a page on Handball.
- 59.7% of the visitors who accessed pages about Badminton and Diving also accessed a page about Table Tennis.

The percentages mentioned in both association rules are called confidence. Confidence can be defined as the number of transactions containing all of the items in a rule, divided by the number of transactions containing the rule antecedents (Cooley, Mobasher, & Srivastava, 1999). Additionally, temporal relationships among data items can be discovered, such as the following (Cooley, Mobasher, & Srivastava, 1997):

- 30% of clients who visited the '/company/products' page had done a search in Yahoo within the past week on keyword w.
- 60% of clients who placed an online order in the '/company/product1' page also placed an online order in the '/company/product4' page within 15 days.

Depending on the purpose of the mining, a traversal pattern may contain backward traversals. Backward traversals consist of references of pages earlier visited. Studying backward traversals can help discover missing hyperlinks, which if added will reduce these traversals, thus making navigation paths shorter and more convenient for the users. A pattern's accesses can also be restricted only to contiguous ones, which can be used for prefetching and caching purposes. A frequent pattern is maximal if does not contain any frequent subpatterns. This can reduce significantly the number of meaningful discovered patterns.

Pattern analysis is the last stage of the Web usage mining process. The patterns that have been produced are reviewed, and useful information is extracted from them. Knowledge query mechanisms, similar to structured query language (SQL), can be used to filter out the patterns. Another approach involves the use of data cubes and OLAP operations. Visualization techniques, such as graphing patterns or assigning colors to different values, can also be utilized to highlight interesting trends in the data. Last but not least, content and structure information can be used to filter out patterns containing pages of a certain usage type, content type, or pages that match a certain hyperlink structure.

Numerous approaches to Web usage mining have been followed, targeted to a wide range of applications. Chen, Park, and Yu (1998) and Nanopoulos and Manolopoulos (2000) have introduced the concept of using the maximal forward references to break down user sessions into transactions for mining access patterns. Yang, Pan, and Chung (2001) have proposed an efficient hash-based method, HMFS, for discovering the maximal frequent itemsets. Spiliopoulou (1999) has presented an algorithm for building aggregating trees from Web logs, then mining the Web access patterns by MINT mining language. (Cooley et al. (1999) have provided a query language on top of external mining software for association rules and for sequential patterns. Another query language for extracting navigation patterns, called MiDAS, has been proposed by Buchner, Baumgarten, Anand, Mulvenna, and Hughes (1999). Xiao and Dunham (2001) have investigated techniques to discover frequently used contiguous sequences of page references, which they call maximal frequent sequences (MFS). They have also developed an algorithm called online adaptive traversal (OAT) pattern mining, to mine MFS. Xing and Shen (2004) have proposed two algorithms, user access matrix (UAM) and preferred navigation tree (PNT), for mining user preferred navigation patterns.

Web Adaptation

Several Web adaptation systems have been developed over the years, mainly based on Web usage mining techniques. The WebWatcher system (Joachims, Freitag, & Mitchell, 1997) suggests links that may interest a user, based on other users' online behaviour. The system is implemented in the form of a proxy server. Each user is asked, upon entering the site, what kind of information he is seeking. Before he departs, the user is asked whether he has found what he was looking for. His navigation paths are used to deduce suggestions for future visitors that seek the same content. These suggestions are visualized by highlighting existing hyperlinks.

The Avanti project (Fink, Kobsa, & Nill, 1996) tries to predict the visitor's final objective as well as her next step. A model for the visitor is built, based partly on the personal information of the visitor and partly on information extracted from her navigation paths. Visitors are provided with direct links to pages that are probably the ones they are looking for. In addition, hyperlinks that lead to pages of potential interest to each visitor are highlighted. The suggestions are extracted with the use of association rules that are applied to the user's model.

A drawback of both the WebWatcher and the Avanti approaches is that they require the active participation of the users in the adaptation process, by asking them to provide information about themselves. On the other hand, Footprints (Wexelblat & Maes, 1999) relies entirely on the navigation paths of the users. The navigation paths of all visitors are recorded and the most frequent ones are presented to the visitor. Additionally, next to each link, the percentage of people who have followed it is displayed.

Perkowitz and Etzioni (2000) have proposed a conceptual framework for adaptive Web sites, focusing on the semi-automatic creation of index pages from clusters of pages. They have developed two cluster mining algorithms, PageGather and IndexFinder. The first one relies on a statistical approach to discover candidate link sets, while the second finds link sets that are conceptually coherent.

The Semantic Web

Since January 2005, the Web has grown by more than 17 million sites, according to monitoring firm Netcraft. This figure exceeds the growth of 16 million sites seen in 2000 when net fever reached its most intense pitch.[1] Significant progress has been made in technologies for publication and distribution of knowledge and information on the Web. People add private, educational, or corporate content. Growth also comes from the rise in blogging, in which users write regularly updated Web journals on various topics. However, much of the published information is not organized, and it is hard to find answers to questions that require more than a keyword search.

The Semantic Web (Berners-Lee, Fischetti, & Dertouzos, 1999) means to address these problems by expressing Web data in forms that are machine-processable, in order to be more efficiently maintained by software agents, thus enhancing precision of search, as well as logical reasoning. The vision behind this concept can be summarized as "giving information a well-defined meaning, better enabling computers and people to work in cooperation" (Berners-Lee, Hendler, & Lassila, 2001).

Ontologies are a key enabling technology for the Semantic Web, since they offer a way to give information a common representation and semantics. Daconta, Obrst, and Smith (2003) distinguish three levels of ontologies: top, middle, and lower domain levels. At the top level, the ontological information represented concerns primary semantic distinctions that apply to every ontology. The middle level represents knowledge that spans domains and may not be as general as the knowledge of the upper level. Finally, the lower level represents ontologies at the domain or subdomain level. This is typically knowledge about domain-specific subject areas. While an ontologist can address the upper and to a certain extent the middle level, the domain expert is absolutely required for the construction and maintenance of the lower level.

Mikroyannidis and Theodoulidis (2005) distinguish between the domain ontology and the ontology of a Web site dedicated to a certain domain. A Web site ontology is strongly related to the topology of the site and is comprised of the thematic categories covered by the site's pages. These categories are the concepts of the ontology. Each Web page, depending on its content, is an instance of one or more concepts of the ontology. The concepts can be related to each other through a number of relationship types, representing the associations the concepts have according to the Webmaster's perception. Figure 1 shows the Web site ontology belonging to the University of Manchester School of Informatics (www.informatics.manchester.ac.uk). The ontology has been built considering the organization of the thematic categories as this is defined in the current topology of the site. The hierarchy's top level contains seven classes: School, Undergraduate Programmes, Postgraduate Taught Programmes, Postgraduate Research, Research, News and Intranet. These are the main thematic categories of the site. These categories are then

Figure 1. The School of Informatics Web site ontology

expanded to more specific concepts, which are represented by subclasses.

It should be pointed out that the Web site ontology is quite different from the domain ontology. The latter describes relationships between the concepts of a domain, whereas the first is based on the organization of the information found in a Web site. The ontology of a domain is usually more complex than the ontology of a Web site related to the same domain. However, the maintenance of a Web site ontology requires considerable effort and has to be performed on a regular basis, since the content of a Web site is constantly updated.

SEMANTIC WEB ADAPTATION

The Semantic Web is undoubtedly a remarkable advance in the area of information management. The magnitude of Web data necessitates the use of machine-processable metadata. Nevertheless, the Web users' needs and requirements should not be neglected in the process of building and maintaining the Semantic Web. Semantic Web adaptation utilizes traditional Web usage mining methodologies and extends them in order to address the ontological perspective of the Semantic Web. Apart from the topology of the Web, which is targeted in a conventional Web adaptation system, semantic Web adaptation also aims to the evolution of Semantic Web ontologies.

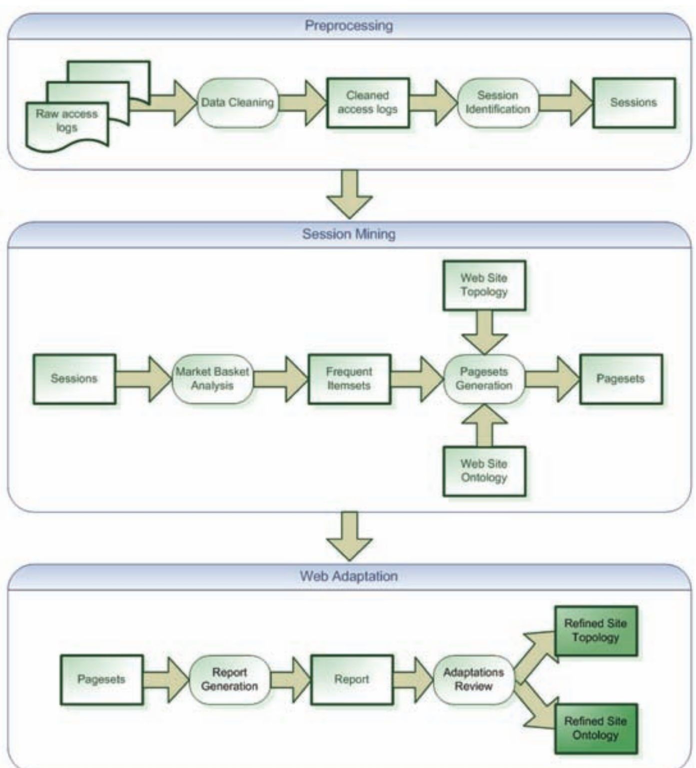
The Heraclitus framework (Mikroyannidis, 2004; Mikroyannidis & Theodoulidis, 2004, 2005) proposes the transformation of the Semantic Web based on Web usage data. Web usage mining and text mining are used for the extraction of knowledge from navigation paths and the adaptation of the physical and semantic structure of the Web. An implementation of the Heraclitus framework has been released as a suite of open source tools (http://heraclitus.sourceforge.net).

Architecture

Figure 2 presents the architecture of the Heraclitus framework. As it can be seen, the inputs of the adaptation process consist of raw access logs, the Web site topology and ontology. The whole procedure aims at the evolution of the topology and ontology of the Web site.

The adaptation starts with a preprocessing stage, during which the data stored in the raw access logs are cleaned and visiting sessions are identified. The sessions are then mined with the use of market basket analysis (Bodon, 2003) to retrieve frequent itemsets. These are then classified based on the Web site topology and ontology in order to produce page sets, that is, sets of pages that are frequently accessed together throughout the same session. During classification, each itemset is assigned its position in the topology and the ontology of the Web site. For the latter, automatic categorization is performed with the use of the support vector machines (SVM) algorithm (Cortes & Vapnik, 1995). SVM has been trained on the thematic categories that are defined in the concepts of the Webmaster's ontology. Each page

Figure 2. Semantic Web adaptation architecture



of the page sets is then assigned by SVM to one or more concepts of the ontology.

Based on the topological and ontological features of the page sets, a report containing proposals for the improvement of the Web site is generated. This report contains proposals for the insertion of shortcut links from source pages to target pages that are frequently accessed together but are currently not linked. It also contains proposals for the change of the appearance of popular hyperlinks. In addition, the report contains proposals for the evolution of the Web site ontology. After the proposed modifications have been revised by the Webmaster, they can be applied to the Web site. The site topology is then refined through the insertion of new shortcut links, as well as changes in the appearance of the existing ones. The ontology is also refined in a number of ways.

Case Study

The Web site of the School of Informatics at the University of Manchester (www.informatics.manchester.ac.uk) was used as a case study for the Heraclitus framework. The topology of the Web site was refined through the insertion of new shortcut links between pages that were not previously linked together, as well as through the highlighting of popular existing links. In addition, the Web site ontology was modified in several ways, based on the outcomes retrieved from the classified page sets.

More specifically, Heraclitus produced two sets of reports: shortcut links reports and highlighted links reports. Page sets of unlinked pages suggest the insertion of shortcut links between these pages, in order to achieve shorter navigation paths. From the page sets of linked pages, changes in the appearance of existing links can be extracted. For example, if an index page and some of its links comprise one or more page sets, then highlighting these links in the index page will provide valuable help to visitors.

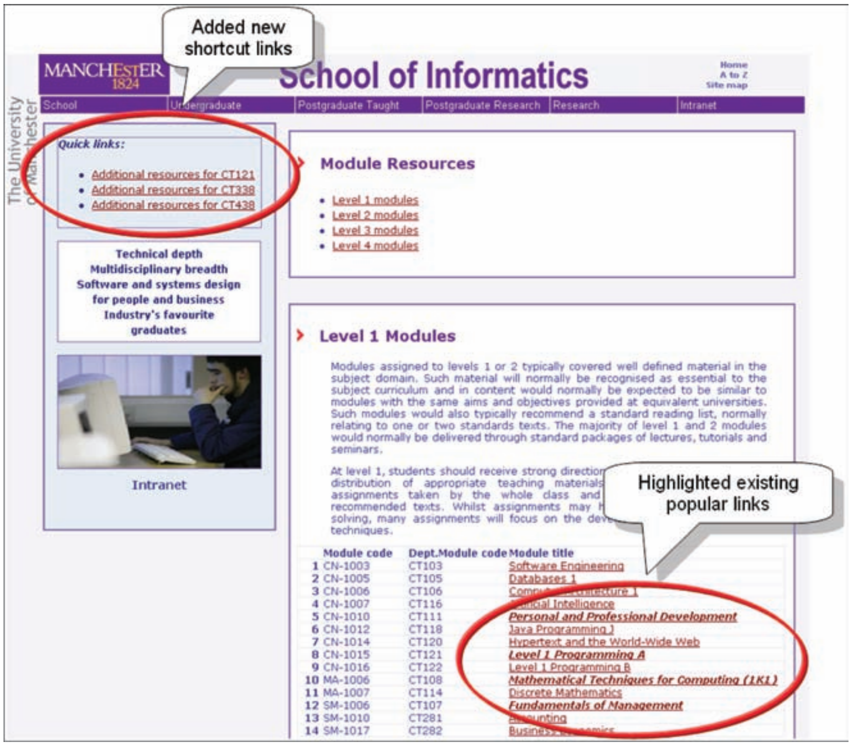
Figure 3 shows an example of a modified Web page, according to the proposed Heraclitus adaptations. The page has been modified to facilitate the navigation of the users during the first semester. Shortcut links to popular courses of the first semester have been inserted in the left side of the page, under the title "Quick links." Moreover, popular links that already existed, such as the hyperlink leading to the page of the "Personal and Professional Development" course, have been highlighted.

The Web site ontology was modified in several ways, based on the outcomes retrieved from the classified page sets. The resulting ontology, after the application of Heraclitus adaptations, is shown in Figure 4. Based on these adaptations, the content organization of the Web site was altered to better satisfy the needs of its visitors. First of all, new associations were discovered between concepts. These associations reflect the interests of the users, as documents belonging to these concepts are frequently accessed together. In particular, new associations were inserted between the following concepts:

- "Research" and "Students"
- "Research" and "Staff"
- "School" and "Students"
- "School" and "Staff"
- "Students" and "Staff"

Reorganization of the concepts' hierarchy was also performed. Further improvements included the creation of new categories, the removal of existing categories, as well as changes to the levels of hierarchy that the concepts belong to. For instance, the "Staff" concept was previously a subconcept of the "School" concept, which resided in the highest level of the ontology. It should be noted that the "Staff" concept has as instances all the Web pages that carry information about the staff members of the school. However, the high frequency with which this concept appeared in

Figure 3. Proposed Heraclitus adaptations in a sample Web page

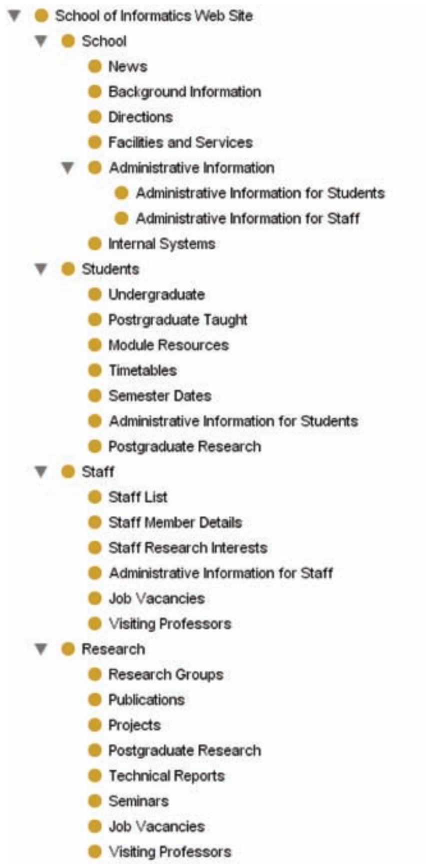


the page sets implies the significance that it has in the interests of the users. It would be thus appropriate to transfer this concept to the top level of the ontology, as shown in Figure 4. Based on the performed classification, the undergraduate and postgraduate programmes were grouped under the more general concept "Students." The "School" concept was also extended to include more subconcepts.

The ontology of the Web site was extended to include multiple instances of concepts or multiple subconcepts. The categorization of the Web pages that was carried out suggested that several pages belong to more than one concept. Moreover, in some cases, Web pages and the corresponding concepts were categorized under different concepts than they previously were in the existing ontology. The Web site ontology should be therefore updated in order to reflect this fact. For example, the "Job vacancies" Web page, which corresponds to the "Job Vacancies" concept, was found to be an instance of both the "Staff" and "Research" concepts. The information contained in this page regards mainly research job posts and is also highly related to the "Staff" concept. This page was previously categorized only under the "School" concept. In the updated ontology, the "Job Vacancies" concept has been placed both under the "Staff" and "Research" concepts. The same modification has been applied to the concepts "Visiting Professors," "Administrative Information for Students," and so forth.

Finally, useful conclusions were deduced about the usage of the Web site. Particularly, the thematic category that was the first in the preferences of the users was, as expected, the "Students" concept. This concept contains all pages that support the school's modules, both undergraduate and postgraduate. This is not surprising, since most of the traffic is generated by the students. Second,

Figure 4. Refined Web site ontology for the School of Informatics



in the users' interests comes the "Staff" concept. The "Research" concept is third, followed by the "School" category. These results can be used to enhance the performance of the server, for example, by the use of additional servers that will host the popular resources, or to promote the problematic concepts by making them more easily accessible.

CONCLUSION

The Semantic Web is undoubtedly a remarkable advance in the area of information management. The magnitude of Web data necessitates the use of machine-processable metadata. Nevertheless, the needs and requirements of the Web users should not be neglected in the process of building and maintaining the Semantic Web.

The Heraclitus framework approaches Semantic Web adaptation from a user-oriented perspective. Transformation of the Web topology and ontology is carried out having as basis the information retrieval tasks of the visitors. Web usage mining and text mining are used for the extraction of knowledge from navigation paths of the visitors. Practicing semantic Web adaptation on a real Web site has provided an insight in navigation difficulties of the users as well as in ways to overcome them.

KEY TERMS

Ontology: A representation of a certain domain, through the definition of concepts, relationships between concepts, and instances of concepts.

Semantic Web Adaptation: The process of transforming the topology and ontology of the Web in order to improve its usability.

Web Access Log: A listing of page reference data. Web access logs are created by Web servers in order to keep track of the requests that occur on Web sites by Web users.

Web Adaptation: The process of transforming the topology of the Web in order to align it with the preferences of the users, thus facilitating their browsing.

Web Mining: Mining data related to the Word Wide Web, such as the content of Web pages, intrapage structure, which includes the HTML or XML code of a page, interpage structure that is the linkage structure between Web pages, usage data that describe how Web pages are accessed, and user profiles, including demographic, registration information, or information found in cookies.

Web Site Ontology: An ontology whose concepts are the thematic categories covered by the pages of a Web site. Each Web page, depending on its content, is an instance of one or more concepts of the ontology. The concepts are related to each other through a number of relationship types, representing the associations the concepts have according to the Webmaster's perception.

Web Usage Mining: An application of data mining methodologies to Web access logs in order to discover trends and regularities in navigation patterns of Web users.

Chapter 1.7
Tips for Tracking Web Information Seeking Behavior

Brian Detlor
McMaster University, Canada

Maureen Hupfer
McMaster University, Canada

Umar Ruhi
University of Ottawa, Canada

ABSTRACT

This chapter provides various tips for practitioners and researchers who wish to track end-user Web information seeking behavior. These tips are derived in large part from the authors' own experience of collecting and analyzing individual differences, task, and Web tracking data to investigate people's online information seeking behaviors at a specific municipal community portal site (myhamilton.ca). The tips discussed in this chapter include: (1) the need to account for both task and individual differences in any Web information seeking behavior analysis; (2) how to collect Web metrics through deployment of a unique ID that links individual differences, task, and Web tracking data together; (3) the types of Web log metrics to collect; (4) how to go about collecting and making sense of such metrics; and (5) the importance of addressing privacy concerns at the start of any collection of Web tracking information.

DOI: 10.4018/978-1-59904-974-8.ch013

INTRODUCTION

Upon first consideration, employing Web tracking to better understand end-user experiences with the Web seems to be a simple process of installing the tracking software, collecting the data over a certain period of time, and conducting the analysis. However, our own experience in setting up, collecting, and analyzing Web tracking data has shown us that the process is surprisingly more difficult than originally expected.

To share what we have learned to help others set up and better utilize Web tracking tools, we have reflected upon what we believe are key tips concerning the use of Web tracking in any Web information seeking analysis. Thus, the overall purpose of this chapter is to discuss the practicalities and usefulness of collecting Web tracking data to help measure and assess the performance and usage of a Website or application, particularly with respect to Web information seeking.

Note that the ideas presented in this chapter are grounded in a research project conducted by the authors over the last three years that investigates people's online behaviors at a municipal community portal site called myhamilton.ca (www.myhamilton.ca). The ultimate goal of the project is to understand the relationships among individual user characteristics such as demographics and personality traits, user attitudes toward and perceptions about accomplishing certain tasks (Web services) online, and actual usage behavior. We believe that an understanding of these relationships will provide insight into how characteristics of the individual, the task, and utilization behaviors affect task performance in an online community environment. We also believe that the capture and analysis of Web tracking data is imperative to reaching such an understanding.

The difficulty in utilizing Web tracking data successfully is in knowing how to position its collection and use within the larger confines of Web information seeking analysis. Web tracking is just one tool that needs to be coordinated with other data collection methods to yield a more comprehensive understanding than Web tracking alone could ultimately provide.

The objective of this chapter is to raise awareness of this point and to suggest techniques and approaches for the collection and analysis of Web tracking information that will aid practitioners in their performance measurement initiatives and understanding of how end-users seek information on the Web. Various tips are presented:

- The need to account for both task and individual differences in any Web information seeking analysis assessment
- The benefits of using a unique ID to link individual differences, task, and Web tracking data
- The types of Web metrics to collect
- How to gather and make sense of the Web metric information that is collected in Web logfiles
- The importance of addressing privacy concerns right up-front in the collection of Web tracking information

We begin by providing background on the need to take both task and individual differences into consideration when investigating end-user Web information seeking behavior. To do this, we provide a general model that describes how task and individual differences affect information seeking behavior. Next, methods to conduct a Web information seeking analysis that allows for the collection of both task and individual differences data are presented. Importantly, these methods include the collection of Web tracking data via the use of Web logs. Using a selective subset of variables from the general model presented earlier, our own myhamilton.ca project serves as a point of illustration. We also provide details with respect to the types of Web metrics to collect and what needs to be done to make sense of these data. Finally, the importance of addressing privacy in any Web information seeking analysis is highlighted.

To help clarify things, find below the following definitions of terms:

- *Information seeking behavior* refers to how people seek information in different contexts (Fisher, Erdelez & McKechnie, 2005).
- *Web information seeking behavior* refers to information seeking behaviors that occur over the Web. Choo, Detlor & Turnbull (2000) identify four main modes

of information seeking on the Web ranging from wayward browsing to goal-directed search (undirected viewing, conditioned viewing, informal search, and formal search) where each mode is characterized by predominant information seeking moves or activities (undirected viewing: starting and chaining; conditioned viewing: browsing and differentiating; informal search: differentiating, monitoring, and extracting; and formal search: monitoring and extracting).

- *Individual differences* are the demographic and psychological characteristics of people that distinguish one person from another.
- *Task* in this chapter refers to the information seeking task an individual user experiences that instills a need for information and motivates the user to satisfy this information need through some sort of information seeking behavior. Task is the context surrounding a person's information need.
- *Web tracking* refers to the automated collection of Web information seeking behavioral data.
- *Web metrics* pertains to the measures by which to assess a person's Web information seeking behavior or to assess and monitor activity on a Website. Examples of commonly used Web metrics include page views, page transitions, and session times.

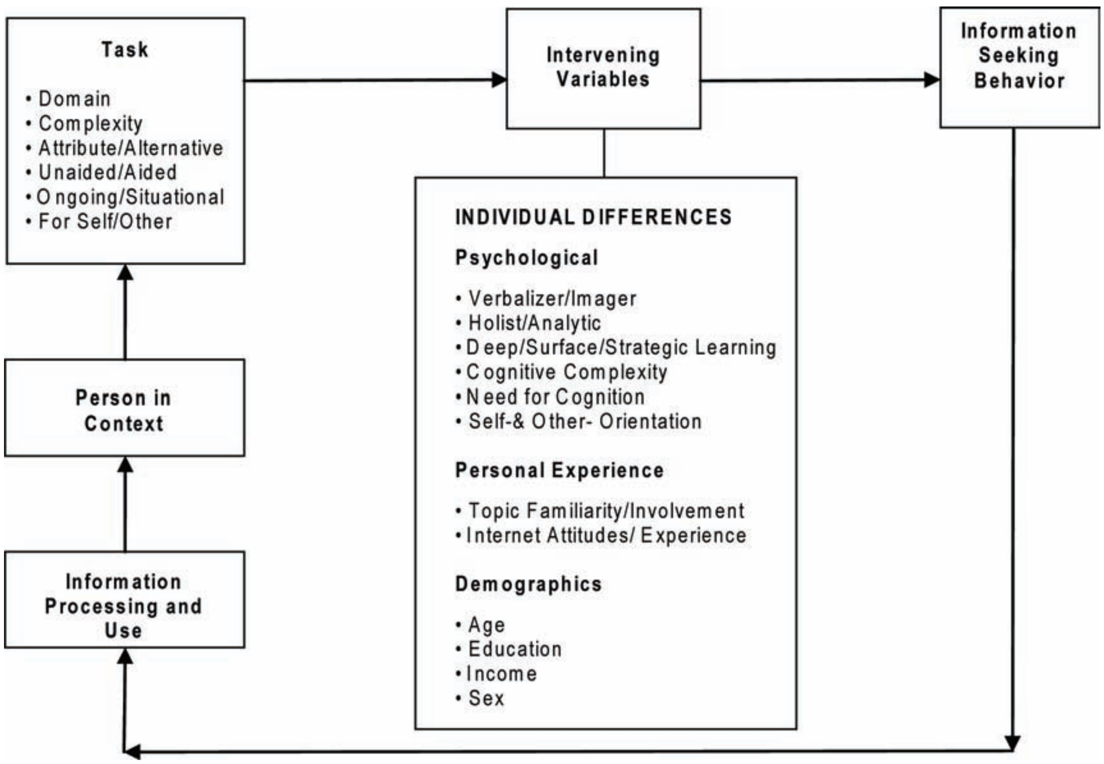
INDIVIDUAL DIFFERENCES, TASKS, AND INFORMATION SEEKING BEHAVIOR

Research concerning online information seeking in both information science and marketing has shown that information seeking strategy depends on the type of information seeking task or its context (e.g., Bhatnagar & Ghose, 2004; Moe 2003; Toms & Trifts, 2006; Wildemuth & Hughes, 2005). Scholars in both fields, as well as those in psychology, also have begun to examine the role of individual differences in online behavior (e.g., Bhatnagar & Ghose, 2004; Das, Echambadi, McCardle, & Luckett, 2003; Dillon & Watson, 1996; Ford, Miller & Moss 2001, 2005a, 2005b; Gugerty, Treadaway & Rubinstein, 2006; Heinström, 2005; Ho, 2005; Martin, Sherrard & Wentzel, 2005; Tuten & Bosnjak 2001). Unfortunately, the study of individual differences in information seeking has tended to take a haphazard approach that has failed to link findings with broader theoretical frameworks concerning information seeking behavior and has neglected to study the effects of individual differences in conjunction with specific seeking contexts (Saracevic, 1991). The work of Ford et al. (2001, 2005a, 2005b) is a notable exception both for its use of Wilson's model of information behavior (Wilson & Walsh, 1996) as a basis for investigation and for its examination of how information seeking complexity and individual differences in cognitive style interact to result in differing information seeking strategies (Ford et al., 2005b).

To situate individual differences within the Web information seeking context, we propose our own model of information seeking behavior that utilizes Wilson's (1999) model as a theoretical foundation (see Figure 1). According to this model, task (analogous to Wilson's "context of the information need" construct) leads to information seeking behavior that is mediated by individual differences variables. The purpose of the model is to illustrate how task and individual differences fit into and influence the end-user information seeking process, and to stress the importance of the need to take both task and individual differences into account when planning any type of Web information seeking analysis assessment.

As Figure 1 shows, with respect to **task**, there are a variety of characteristics about a task that can influence an end-user's information seeking behavior. For instance, prior research has found

Figure 1. How task and individual differences affect information seeking behavior



substantial differences in information seeking patterns across tasks and between product categories or information domains (e.g., Bhatnagar & Ghose, 2004; Trifts & Toms, 2006; Wildemuth & Hughes, 2005). These differences, in part, can be explained by the complexity of the information seeking task, the extent to which the task is clearly structured, whether one is seeking information for oneself or for someone else (Hupfer & Detlor, 2006), and semantic differences between search domains (Byström & Järvelin, 1995; Vakkari, 1999, pp. 825). Ford et al. (2003) suggest that complex tasks require a conceptual broadening of useable terminology to reflect broader search concepts. Conversely, simple tasks would be ones in which all essential concepts necessary to complete the information seeking task are fully specified in the task instructions. In a consumer decision making context, this conceptual broadening may be closely related to how well a consumer is able to mentally formulate the parameters of an information search. For example, consumers who are well aware of their current product needs may be easily able to articulate this need in the form of a search query (e.g., buying a particular DVD), but a decision made with less specificity (e.g., planning a vacation with no particular destination in mind) may require broadening of the search parameters to learn more about the various alternatives available.

Even within a specified information domain, task complexity is influenced by such factors as the number of alternatives available, the number of dimensions of information on which the alternatives vary, and time pressure (Payne, Bettman & Johnson, 1993). Greater complexity in an information seeking task often leads to more heuristic-based processing of information. Decision strategies that require processing information by attribute as opposed to alternative are thought to be easier to undertake.

In the context of online information seeking, tasks that require people to search by attribute as opposed to alternative may be cognitively less complex and require less time at the general search tool level. Therefore, even within a specified domain, differences in information seeking effort allocation may occur, depending upon a person's information seeking orientation (Huneke, Cole & Levin, 2004). That is, whether an individual is engaging in attribute-based or alternative-based processing of information affects the allocation of information seeking effort between general search engines versus specific Websites (Toms & Trifts 2006). Those who are engaged in alternative-based processing are more focused on finding an appropriate source of information and thus allocate a greater amount of their information seeking effort at a general search engine as opposed to in-site search.

Other characteristics of the task shown in Figure 1 that can affect information seeking behavior are whether the information seeking task is aided/unaided or ongoing/situational. The former refers to the extent to which Web information seeking is assisted by interactive decision aids. For example, in the domain of online shopping, Haubl and Trifts (2000) found that interactive tools that assisted consumers in their initial screening of alternatives substantially reduced the amount of information seeking undertaken and improved decision making. Despite the initial learning that is required, in the long run the use of interactive decision aids should reduce task complexity such that users will be able to devote less effort to obtain the required information than they would expend if unassisted. The latter refers to whether information is needed on an ongoing basis, such as when an individual has an interest in a product category or topic but does not intend to make a decision immediately, or whether information is needed for present use, such as a pre-purchase situation in which a decision is imminent.

As Figure 1 shows, **individual differences** play an important role in terms of mediating the effect of task on information seeking behavior in terms of the information seeking strategy or process chosen, as well as its effectiveness. These differences may include an individual's familiarity or level of involvement with the information topic (Moorthy, Ratchford & Talukdar,1997), experience with the Internet (Bhatnar & Ghose, 2004), perceptions of Web-based information seeking (Ford & Miller, 1996), and enduring psychological traits (e.g., Ford et al., 2001; 2005a; 2005b).

For example, Bhatnar and Ghose (2004) found that users with greater experience with the Internet and more education utilized the Internet more frequently. Other demographic characteristics, including age and sex, also have been associated with differences in Web information seeking patterns. Ford et al. (2001) established that information retrieval effectiveness was associated with males while retrieval failure was associated with females. Women felt that they were not in control of their information seeking; they were unable to avoid irrelevant material and stay on target. Men, however, were confident that they were in control and could bypass extraneous content. Educational research conducted with children also has found sex differences in information seeking such that boys searched differently from girls and were able to acquire more target-specific and target-related information. Boys filtered information at an early stage but girls were linear and more thorough navigators (Roy & Chi, 2003).

As Figure 1 illustrates, there are several psychological differences that may influence information seeking behavior in terms of an individual's propensity to engage in elaborate, effortful processing versus effort minimization and reliance on heuristics. Explained below, these include: verbalizer /imager and holistic/analytic cognitive styles; deep, surface and strategic learning approaches; cognitive complexity; Need for Cognition; and Self- and Other-Orientation.

Cognitive Style

Individuals differ in the strategies that they use to seek and process information, and they tend to favor certain strategies, or cognitive styles, on a consistent basis. Among these styles, verbalizer/imager and holist/analytic are the two dominant dimensions (Riding & Cheema, 1991). The verbalizer/imager dimension refers to a preference for and facility with tasks and information that are presented in a verbal versus visual format; verbal and spatial ability are closely related measures (Ekstrom, French & Harman, 1976). Analytic individuals perceive components of complex stimuli as discrete elements and are better able to analyze and impose structure than those who are holist, with their tendency to perceive stimuli in a holistic or global manner. Where Internet searching is concerned, Wang, Hawk and Tenopir (2000) found that holist searchers experienced more difficulty and confusion than analytic users. Ford et al. (2001) found that poor retrieval was linked to a verbalizer cognitive style, as well as perceptions that the Internet's graphic elements were of little value. Similarly, Gugerty et al. (2006) demonstrated that superior spatial, rather than verbal, ability was associated with more favorable computer and Internet attitudes, and also had an indirect effect on information seeking performance. Ford et al. (2001) found no relationships between holist or analytic cognitive styles and retrieval effectiveness, but did find relationships among holists, imagers and Boolean searching and among analytics, verbalizers and Best-match searching (2005a; 2005b). It also appears that cognitive style effects are more important for novice than for experienced Internet searchers (Palmquist & Kim, 2000). Such evidence suggests that individual differences in cognitive style affect not only the information seeking process but also its effectiveness.

Learning Style

Those with a surface approach describe learning as knowledge reproduction achieved through rote learning and memorization. They are passive uncritical learners who devote relatively little effort to information seeking (Ford, 1986; Entwistle & Tait, 1995). Deep learners, on the other hand, view learning as a process that creates knowledge through the synthesis and assimilation of new information. They seek a broad range of information sources using a variety of information seeking strategies. Strategic learners are able to choose either deep or surface learning approaches as appropriate to the task at hand. Analysis of self-reported information seeking behavior has found that a surface approach to learning was associated with a fast surfing information seeking strategy in which users experienced problems with critical analysis and had difficulty judging the relevance of retrieved documents (Heinström, 2005). They also demonstrated confirmatory bias and preferred to access information using only a few documents. In contrast, a deep diving approach characterized those with either deep or strategic learning styles; these individuals were effortful information seekers who sought high quality documents. In addition, Ford et al. (2005a) have found that individual items in the surface learning style (fear of failure and poor time management) were linked to poor retrieval. As with cognitive style, it appears that learning style affects both the information seeking process and its outcomes.

Cognitive Complexity

Those who are cognitively simple tend to see the world in binary terms such as black and white or right and wrong, while those who are cognitively complex are able to see shades of grey and recognize that the validity of a given viewpoint may vary with circumstances. Higher levels of cognitive complexity appear to be associated with poor retrieval (Ford et al., 2001).

Need for Cognition

Individuals with a high Need for Cognition (NFC) enjoy thinking and have a greater tendency to elaborate upon, structure and evaluate information (Cacioppo, Petty & Kao, 1984). They engage in more effortful decision making than those who are low NFC and arrive at better information seeking outcomes (Bailey, 1997). High NFC users also have more favorable attitudes toward Websites with complex verbal and simple visual elements (Martin et al., 2005). NFC is positively correlated with Web information usage (Tuten & Bosnjak 2001) and has a direct impact on self-reported information seeking behavior (Das et al., 2003). Finally, investigation of information seeking at online grocery stores has found that high NFC shoppers, compared with low NFC consumers, investigated more URLs and spent more time reading (Ho, 2005).

Self- and Other-Orientation

These characteristics describe differences in an individual's propensity to be concerned with oneself versus others by tapping gender-related traits that pertain to an independent (Self-Orientation) versus interdependent (Other-Orientation) self-concept orientation (Hupfer, 2001). Self- and Other-Orientation predict Internet use frequency and preferences that male-female indicators often fail to explain. The two scales interact to predict how often individuals seek information online (Hupfer & Detlor, 2006) both for themselves (self-relevant information) and for those close to them (other-relevant information). Other-Orientation also is positively related to usage rates for Internet applications with relationship implications, such as greeting cards (Hupfer & Detlor, 2007a). Furthermore, the two scales interact to predict the importance to an individual of Website characteristics that imply an information-rich environment versus navigational aids that ease processing and maximize efficiency (Hupfer & Detlor, 2007b).

METHODS FOR COLLECTING INDIVIDUAL DIFFERENCES, TASK, AND WEB TRACKING DATA

Recognizing the importance of both task and individual differences in Web information seeking behavior, attention now turns to the methods that allow for the collection of task, individual differences, and information seeking behavior data in a Web information seeking analysis. These methods invariably involve the collection of Web tracking activity via the use of Web logs, but tracking alone is insufficient for a thorough information seeking analysis. Web tracking captures information seeking behavior with Web logfiles, but other data collection instruments, such as questionnaires and interviews, are required to collect individual differences and other task-related data.

In closed environments, like laboratories, researchers can control research participants' information seeking tasks by giving them explicit descriptions or instructions for their tasks and can ask them to complete surveys to collect individual differences data. Closed environments also allow researchers to require that participants use specific software in the lab where their Web activity will be tracked. Other advantages of the closed environment include the opportunity to modify the information seeking tools that are used (e.g., browsers, interfaces), control the available functionality and even provide interactive decision aids. However, closed environments are not without their drawbacks. Processing large numbers of participants through laboratory sessions requires considerable time and resources. In addition, requiring subjects to conduct contrived searches in an artificial setting or scenario may compromise the validity and generalizability of any research results.

Richer Web information seeking analyses are more likely to be found in open environments where end-users can conduct real-life information seeking tasks that are of relevance and importance to them and that take place within natural environments and settings (e.g., the workplace, the home). In open environments, researchers are able to observe natural behavior patterns and collect data that affords greater validity and generalizability. However, conducting Web information seeking investigations in open environments presents its own challenges for the proper collection and analysis of task and individual differences data. For example, dynamic IP addressing prevents the linking of a person's Web tracking data with any individual differences data that is collected through user profiles or questionnaires. Knowing what task prompted a user to turn to the Web to seek information also is problematic in terms of understanding the type of task and its attributes.

There are various ways to go about capturing task, individual differences, and Web behavior data, but a critical component is the ability to link all three types of data together for a specific individual. It probably is easiest to create this linkage in a closed environment. However, if researchers and practitioners want to take advantage of the benefits afforded by Web information seeking analyses conducted in open environments, they must devise a means of connecting these various data sources. We did this, quite successfully, in our own research project at a municipal/community portal site called myhamilton.ca. The project involved the use of two surveys (one pertaining to task; the other pertaining to individual differences) and the collection of Web tracking data to yield a robust understanding of Web user information seeking behavior. Note that a selective subset of task and individual differences variables from the general model presented above were used in our myhamilton.ca research project. Importantly, a unique identification feature linked participants' actual portal activity to demographic, personality and attitude data. To do this, we had to work closely with the portal development group to ensure that the study's data collection instruments (i.e., Web tracking and online surveys) were incorporated directly within the portal's design.

We believe that the use of a unique ID to link data collected in the user surveys to the Web tracking metrics collected in the Web logs is a key strength of our research project. By linking these data sources and triangulating results, we are able to arrive at a rich understanding of end-user online behavior. For example, regressions or path analyses are being used to determine how well individual differences predict task self-reports and actual usage behavior. Further, cluster or discriminant analysis techniques are being used to establish the characteristics of low, medium and high usage groups.

As mentioned above, two types of Web surveys were administered to people who consented to participate in the project. The first of these was an individual differences (user characteristics) survey that collected basic demographic information, personality traits, and technology background on each participant. Items were based on those found in a recent investigation by the authors (Hupfer & Detlor, 2006), the Georgia Institute of Technology's annual GVU WWW User Surveys (cc.gatech.edu/gvu/user_surveys), and Ford and Miller's (1996) scales that measure perceptions of Web-based information seeking (see Appendix A for a list of the individual differences questions used in this project).

The second type of survey was a brief user task evaluation. Eliciting attitudes towards conducting a specific online activity and perceptions of the task's importance, these surveys were administered after participants had completed a given activity on the portal interface (see Appendix B for the actual questions used to measure participants' attitudes toward and perceptions of tasks). These data were collected during short time windows pertaining to a few specific portal activities, such as paying a fine or purchasing a dog license.

In terms of Web tracking, like the two surveys, metrics were collected only from portal users who had agreed to participate in the study. The portal was designed to facilitate metric collection through third party applications hosted on the portal's back-end Web servers. Specific detail concerning the type of Web metrics that were collected and analyzed are discussed in the following section.

WEB METRICS TO COLLECT AND TECHNIQUES FOR ANALYZING THEM

In general, the various sources of Web logs can be classified as either server-level or client-level data sources (Srivastava et al., 2000). The primary metrics in our study were based on server-level data generated through a custom programmed server-side plug-in, and first-party cookies stored on the client-side. These metrics included the following: page attributes such as page views, page transitions, and HTTP referrer information; temporal attributes such as history time stamps, and session times; and visitor attributes such as user identification tags, and remote host information. Consequently, a composite of these primary Web log metrics provided us with the desired analytics output related to information seeking behaviors of end users. Table 1 shows the interrelationships among the various Web log metrics that we used and their sources, as well as the associations among the Web log metrics and their resulting composite analytics.

The advantage of using a customized server-side plug-in rather than other available logging methods such as Web server logs, client-side tracking utilities, and page tagging scripts is that the overall process affords more control for updates and modifications, and also entails less time and effort to clean the data and prepare it for further

Table 1. Summary of Web log sources, metrics, and composite analytics

Web Log Metrics	Sources of Web Log Metrics			Composite Analytics

Remote Host Information	•			•		•

analysis (e-consultancy, 2003). Compared to Web server logs, custom logfiles suffer from fewer inaccuracies and redundancies (e-consultancy, 2003; Murata & Saito, 2006). With respect to control, a server-side plug-in allows greater autonomy than a client-side remote tracking utility where there is increased dependency on client platform capabilities and end user intentions (Winett, 1998). Similarly, vis-à-vis page tagging scripts where the deployed solution is typically outsourced to an application service provider (Beasley, 2002; e-consultancy, 2003), a server-side plug-in offers more control over the development and maintenance of an application interface.

In our study, the server-side plug-in was designed to poll several collections and properties of the server-side objects including request, response, and session objects in order to retrieve values pertaining to attributes of visited site pages, times spent on each page and in each user session, and unique visitor identification values stored in client-side cookies.

In addition to using a customized server-side plug-in for the collection of Web metrics data, our study utilized first-party cookies to track visitors. This method is regarded as more reliable than using third-party cookies used by hosted analytics vendors as recent Internet statistics show that 12%-17% of Internet users block third-party cookies while only 2%-5% block first-party cookies (WebTrends, 2005). By storing automatically generated unique identifiers on users' workstations, persistent cookies allow the identification of unique site visitors which can prove to be extremely valuable in determining the reach and audience penetration of a Website.

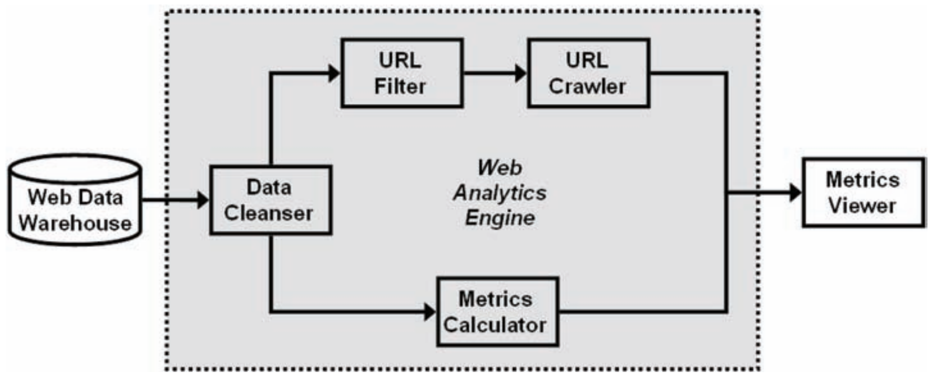
To generate the composite metrics described in Table 1, we created and utilized our own *Web analytics toolkit*. Overall, the collection of singular Web log metrics through server objects and cookies, as shown in Table 1, facilitates the formation of a Web data warehouse, which is regarded as the first step in devising a Web analytics toolkit (Sen et al., 2006). The formation of a Web data warehouse enables simple decision support services through channel traffic reports.

The second step in developing a Web analytics toolkit is to aid sophisticated visitor behavior tracking (Sen et al., 2006) which can only be enabled through additional structured statistical procedures and logic querying methods. In our research study, we did this by following the three phases suggested for Web usage mining studies, namely: 1) *pre-processing*, 2) *pattern discovery*, and 3) *pattern analysis* (Srivastava et al., 2000). The pre-processing phase cleanses, sorts and formats the raw data into organized segments of information (e.g., establishing sequence of activities through sorting first by cookie-based user identifiers and then by server session identifiers). This information feeds into the pattern discovery phase which converts raw logs into data abstractions that are pivotal to the analysis of usage patterns (e.g., deriving session length information from time stamps and page views). The pattern analysis phase calculates descriptive statistics and usage metrics that can help to identify different user clusters based on their patterns of information seeking. Overall, these three phases enable the transformation of dimensions of Web activities that are measurable into those that are meaningful within the context of the analysis of users' information seeking behaviors.

Unlike other Web analytics studies that undertake the development of a self-contained prototypical Web usage mining system as part of the overall research project (Srivastava et al., 2000; Wu et al., 1998; Zaiane et al., 1998), the Web analytics engine used in our study was based on a selection of self-programmed application macros, third party tools, and customized scripts.

Figure 2 shows a high level schematic of the Web analytics engine depicting the various functional modules that were used to operationalize the three phases of Web usage mining. While the data cleanser module enabled the pre-processing

Figure 2. Components of the Web analytics engine



phase, the URL filter and crawler, as well as the metrics calculator, enabled the pattern discovery and pattern analysis phases.

In terms of custom applications, server side scripts using SQL (structured query language) were deployed to extract data from tables in the data warehouse and to export into a format suitable for spreadsheets and statistical analysis applications. In the data cleanser module, Excel macros were utilized to cleanse the data and organize it into meaningful segments that were to be used in metrics calculations. The URL filter allowed us to form clusters of Webpages based on their frequency and mode of access. For instance, Website landing pages were identified by noting external referrer Websites, and search tools were recognized by query information such as keywords contained in URLs. Ultimately, a dictionary of landing pages was compiled to facilitate page lookups during the analysis of online user activities.

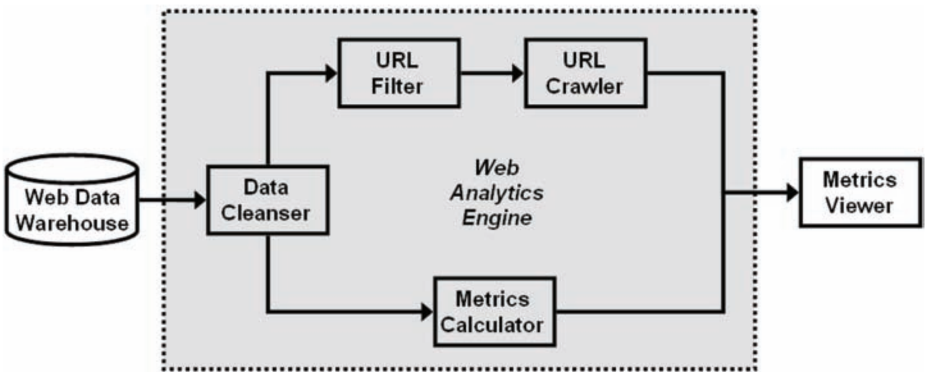
The information derived from the URL filter was further refined by mapping the URLs to the title of the Webpages. These titles were obtained by running the list of URLs through an Internet-based Web crawler utility which parses Webpages for various types of metadata. In this case, the only metadata that was of interest was the title tag pertaining to the Webpages referenced by the URLs. Finally, the metrics calculator module comprised spreadsheet functions and macros in Excel and analysis widgets in the SPSS statistical application. The metrics calculator was used primarily to report descriptive statistics and produce cluster analysis results that could be viewed in text, table or graphical formats through the metrics viewer module.

The Web analytics engine allowed us to perform a composite analysis of Web log metrics from server-side and client-side sources. Specifically, as shown in Table 1, the Web analytics engine allowed us to define a hierarchical view of user activities based on visitor footprints, navigation tracks, and information seeking trails.

At the lowest level of user information seeking pattern identification, a *visitor footprint* represents "a single clickstream record created by the interaction of the visitor with a page on a Website" (Sen et al., 2006). In establishing visitor footprints, various clickstream metrics such as unique cookie based user identification, server based session identification, time stamp information, referrer page URLs and destination page URLs can be compiled into simple records of online user activities. In our study, the data cleanser and URL crawler modules in the analytics engine were utilized to establish these visitor footprints. Figure 3 shows an extract of nine footprints pertaining to a sample user, User-34.

An aggregation of visitor footprints enables the formation of *navigation tracks* which provide

Figure 3. Extract of visitor footprints



a chronological history of a user's activities on a Website (Sen et al., 2006). In our study, the configuration of each visitor navigation track comprised the entry point to the Website, the path of Webpages that were traversed in each user session, along with the average time spent per page, content page requests per session, search queries per session, and the exit point from the Website. Custom programmed spreadsheet macros in the metrics calculator module of the analytics engine processed the visitor footprint information to reveal these navigation tracks. Figure 4 shows the extract of navigation tracks pertaining to the visitor footprints shown in Figure 3.

Based on information from visitor footprints and navigation tracks, *information seeking trails* characterize the deepest level of pattern discovery employed in our study. Information seeking trails can be discerned by using clustering algorithms which can group similar user beliefs, attitudes and behaviors (Sen et al., 2006). In our study, the information seeking trails were analyzed through composite analytics that acted as surrogate measures to identify scanning, searching and browsing

moves on Websites. These information seeking moves were further assembled and classified into modes of information seeking such as undirected viewing, conditioned viewing, informal search, and formal search (Aguilar, 1988; Choo et al., 2000). Episodes of information seeking were analyzed using recursive procedures in spreadsheet macros that hinged on multiple passes through visitor footprints and navigation tracks. Figure 5 shows an extract of the additional surrogate metrics that were used to formulate the archetypical information seeking episodes.

Undirected viewing episodes can be identified by observing the most common entry points in visitor navigation tracks and calculating the average number of page requests and the average time spent on Webpages. Since users engaged in undirected viewing modes demonstrate broad scanning web moves (Choo et al., 2000), these modes typically consist of navigation tracks that start at main landing pages such as the Website homepages and sitemaps, and exhibit high average number of page requests and low average time spent per Webpage.

Conditioned viewing episodes can be tallied by identifying similarities in entry and exit points between visitor navigation tracks for the same user. This can be accomplished by calculating the dot product of page paths in visitor navigation paths. Since users engaged in conditioned viewing episodes are interested in selected topics and specific types of information (Choo et al., 2000), these episodes also will typically exhibit a lower ratio of search queries to page requests.

Informal search episodes show signs of unstructured search efforts (Choo et al., 2000) and can be identified by using surrogate measures such as observing navigation tracks that consist of references to external search engines, high average number of sessions with multiple search queries, and low average time spent per Webpage.

Formal search episodes are emblematic of users who make a purposeful and planned effort to acquire specific information (Choo et al., 2000). Using information available in visitor navigation tracks and other surrogate measures of information seeking modes, these episodes can be expected to exhibit a high average number of sessions that started with a search page, a low average number of page requests, and high average time spent per page.

The next step in our research study will involve further examination of the four archetypical episodes of information seeking outlined above. Specifically, we plan on linking the Web analytics information we collected in terms of visitor footprints, navigation tracks and information seeking trails to the data we collected through the individual differences questionnaire and task attitudes survey. Doing so will allow us to better understand the associations between Web behavior and the specific characteristics of users or groups of users.

ADDRESSING PRIVACY IN WEB INFORMATION SEEKING ANALYSIS

A final tip for any person wishing to conduct Web information seeking analysis in real-world settings (i.e., non-laboratory environments) is the need to address privacy concerns during the project's initial stages and to design Web data collection and analysis methods with privacy in mind. Ethics boards at academic institutions have always cautioned researchers about the need for anonymity and/or confidentiality. Academics, industry analysts and privacy advocates also have raised concerns about the vast amount of data that is collected using passive devices, such as adware, cookies, spyware and Web viruses, to record online behavior (Marshall & Swartwout, 2006). Such calls for privacy protection are warranted.

For example, the need to preserve privacy with Web log analysis became a highly public debate in the summer of 2006 after America-On-Line (AOL) posted query log data (approximately 20 million search inquiries obtained from over 650,000 users over a three month period) to a publicly accessible Website. These data, which were intended for academic use, assigned each user a unique ID and included the date and time of each query as well as addresses of Websites that were visited after searching was concluded. The AOL team that released the data intended to provide researchers with the opportunity to analyze search patterns and strategies over time without having to disclose any personally identifiable information.

Unfortunately, it rapidly became apparent that the specification of search parameters could in some cases permit the identification of individuals (Barbaro & Zeller, 2006; Hansell 2006a). These data were quickly removed from the site, but not before the data had been downloaded and circulated (Barbaro & Zeller, 2006). The ensuing media furor informed readers about how much data is stored by major search engines (Zeller, Jr. 2006a), how advertisers used search history for segmentation and targeting purposes (Hansell, 2006b) and also advised them as to how they could protect their identity online by using proxy servers and by deleting browser cookies (Biersdorfer, 2006). In late August 2006, AOL dismissed a researcher and project manager, and their chief technology officer resigned (Zeller, 2006b). AOL also announced plans for the implementation of new technologies that would protect privacy and restrict access. Academic opinion concerning the data's use has been divided; the very real privacy concerns have been acknowledged, but at the same time, the availability of a very large and current data set has immeasurable value for those who investigate personalization and information retrieval (Hafner, 2006).

With our own myhamilton.ca research project, we were very aware of the need to address privacy issues at the outset. In our initial discussions with the portal project team, we agreed that each user would be assigned a unique ID that would allow us to link tracking logs with survey data. Participant identities would not be released to us and the portal staff would handle the distribution of incentives to those who participated in our research. While these measures ensured anonymity, we later were confronted with the ramifications of municipal privacy legislation requirements. These concerns were further exacerbated by a portal privacy breach that resulted in the inadvertent broadcasting of people's personal dog licensing information and the attendant negative press in the local media. The ensuing privacy impact assessment conducted on our research project required documentation of the flow and storage of both the survey and tracking data. This documentation included the names of all tables where data was stored, a description of the programs that accessed and updated the data, and the process by which the data would be sent to our research team. The city also planned to delete all data once our research team confirmed its safe receipt at the conclusion of the data collection period.

The city's privacy assessment identified one particularly important outstanding issue in that the city had no means to control or prevent the possible misuse of the survey's demographic information and Web tracking information, both of which resided in the city's databases. This situation arose because participants' unique IDs were stored within the city's databases and thereby created the potential for unauthorized linking of this information. Addressing this concern required extensive and costly program code and database changes. Consequently, rather than storing participants' unique IDs within the user profile table in the city's database, unique IDs were embedded in session cookies that were transmitted between a user's computer and the City of Hamilton's servers. Using session cookies that contained unique IDs allowed us to track user behavior individually but eliminated the need to store a unique ID in a database resident on one of the city's servers that possibly could have been used as a foreign key to access and link together a person's private information.

Elimination of unique IDs within the user profile table also caused us to rethink the way we handled the distribution of participant incentives. Some mechanism was required to identify which participants had participated in the study so that we could contact them and distribute gift certificates. To facilitate this, a field was created in the user profile table to simply act as a flag that would indicate whether or not a particular user had agreed to participate in our research project. This flag allowed us to identify those people who participated in the study but it did not allow us to associate a person's research data with their personally identifying (contact) information.

These changes to our data collection methods required an additional review of our protocol by the McMaster research ethics board and the amendment of our call for participation and consent form in order to clarify privacy implications. Specifically, potential participants were informed that privacy had been built into the methods by which data would be collected and stored. In terms of databases, the unique ID would be stored only in three raw data tables that contained the Web tracking and survey data. No link would exist between these tables and any other contained in the myhamilton.ca database, and no personally identifiable information would be sent to the McMaster research team. All of these revisions, the additional ethics review, and further testing of our data collection instruments delayed the project's launch for over six months. A better understanding of privacy legislation and its impact for our research would have allowed us to avoid both the delay and the expense.

CONCLUSION

To provide insight into methods for conducting a Web information seeking analysis, we presented several tips. First, we raised awareness of the importance of individual differences and tasks in understanding information seeking behavior. We encourage practitioners and researchers to include the collection and analysis of task, individual differences, and behavioral data in any Web information seeking analysis design. The second tip spoke to devising methods that collect task, individual differences, and Web tracking data and provide a means to link these data sets together. We provided our own research project at myhamilton.ca as an example for others to follow in this regard. The two surveys (see Appendices A and B) may help others structure similar research instruments to collect data on tasks and individual differences. The third and fourth tips provided guidelines on which Web metrics to collect and how to go about analyzing them. Though many alternative Web metrics and methods of analysis exist, we anticipate that our description of the Web metrics we collected and our illustration of their analysis will assist others in their own investigations. Finally, we discussed the need to address privacy concerns right up-front in the collection of Web tracking information so as to avoid lengthy and costly delays in conducting a Web information seeking analysis. By paying attention to these five tips, both academic researchers and practitioners can ensure that their Website performance measurement initiatives run smoothly.

KEY TERMS

Individual Differences: The demographic and psychological characteristics of people that distinguish one person from another.

Information Seeking Behavior: Refers to how people seek information in different contexts (Fisher, Erdelez & McKechnie, 2005).

Task: In this chapter, refers to the information seeking task an individual user experiences that instills a need for information and motivates the user to satisfy this information need through some sort of information seeking behavior. Task is the context surrounding a person's information need.

Web Information Seeking Behavior: Refers to information seeking behaviors that occur over the Web. Choo, Detlor & Turnbull (2000) identify four main modes of information seeking on the Web ranging from wayward browsing to goal-directed search (undirected viewing, conditioned viewing, informal search, and formal search) where each mode is characterized by predominant information seeking moves or activities (undirected viewing: starting and chaining; conditioned viewing: browsing and differentiating; informal search: differentiating, monitoring, and extracting; and formal search: monitoring and extracting).

Web Metrics: Pertains to the measures by which to assess a person's Web information seeking behavior or to assess and monitor activity on a Website. Examples of commonly used Web metrics include page views, page transitions, and session times.

Web Tracking: Refers to the automated collection of Web information seeking behavioral data.

APPENDIX A: INDIVIDUAL DIFFERENCES QUESTIONNAIRE

Note that some of these questions and their responses pertain to the City of Hamilton and a Canadian context. Modifications would be necessary if administered to a different sample population.

AGE

How old are you?

- Under 18
- 18-24
- 25-29
- 30-34
- 35-39
- 40-44
- 44-49
- 50-54
- 55-59
- 60-64
- 65+
- Prefer not to say

SEX

Are you?

- Male
- Female
- Prefer not to say

RACE

How would you classify yourself?

- Aboriginal
- Asian
- Black
- East Indian
- Hispanic/Latino
- Middle Eastern
- Multi-Racial

West Indian
White
Other
Prefer not to say

KIND OF AREA YOU LIVE IN

Which of the following best describes the area you live in?

Urban
Suburban
Rural
Prefer not to say

Location in Hamilton

Which geographical area of Hamilton best categorizes the area you live in?

Hamilton East
Hamilton Central
Hamilton West
Dundas
Ancaster
Flamborough
Stoney Creek
Mountain West
Mountain East
Mountain Central
Other
Prefer not to say

Language

At a general conversational level, which of the following languages do you speak? Indicate all that apply.

English
French
Arabic
Bengali
Cantonese
German
Hindi/Urdu

Indonesian
Italian
Japanese
Mandarin
Polish
Portuguese
Russian
Spanish
Other
Prefer not to say

Marital Status

What is your current marital status?

Single (never married)
Co-habiting
Married
Separated/Divorced
Widow/Widower
Prefer not to say

Education

What is your highest education level obtained?

Primary School
Secondary (High) School
Vocational/Technical/Community College
University Undergraduate (bachelors degree)
University Graduate (masters/professional/doctoral degree)
Prefer not to say

Occupation

Your current primary employment status is

Employed
Unemployed
Student
Retired
Other
Prefer not to say

Occupation (cont'd)

Which of the following categories best describes the **industry** you primarily work in (regardless of your actual position)?

Agriculture
Arts, Entertainment, and Recreation
Broadcasting
Construction
Fishing & Hunting
Education
College, University, and Adult Education
Primary/Secondary (K-12) Education
Other Education Industry
Finance and Insurance
Forestry,
Government and Public Administration
Health Care and Social Assistance
Homemaker

Which of the following best describes your role in industry?

Administrative Staff
Consultant
Junior Management
Middle Management
Researcher
Self-employed/Partner
Skilled Laborer
Student
Support Staff
Temporary Employee
Trained Professional
Upper Management
Other
Prefer not to say

The organization you work for is in which of the following:

Public sector (e.g., government)
Not-for-profit sector
Other
Private sector (e.g. most businesses and individuals)
Don't know
Prefer not to say

Household Composition

What is the number of adults 18 and over living in your household?

0
1
2
3+
Prefer not not say

What is the number of children age 4 and under living in your household?:

0
1
2
3+
Prefer not not say

What is the number of children ages 5 to 9 living in your household?:

0
1
2
3+
Prefer not not say

What is the number of children ages 10 to 13 living in your household?:

0
1
2
3+
Prefer not not say

What is the number of children ages 14 to 17 living in your household?:

0
1
2
3+
Prefer not not say

Household Income

What is your household income before taxes?

Less than $20,000
$20,000-$39,999
$40,000-$59,000
$60,000-$79,999
$80,000-$99,999
$100,000-$119,999
$120,000-$139,999
$140,000-$159,999
$160,000-$179,999
$180,000-$199,999
More than $200,000
Prefer not to say

Years on the Internet

How long have you been using the Internet (including using email, gopher, ftp, etc.)?

Less than 6 months
6 to 12 months
1 to 3 years
4 to 6 years
7 years or more
Prefer not to say

Community Building

Complete the following sentence in the way that comes closest to your own views: 'Since getting on the Internet, I have...'

Become MORE connected with people like me
Become LESS connected with people like me
Become EQUALLY connected with people like me
Don't know
Prefer not to say

Self- versus Other-Orientation*(taken fromHupfer, 2001)*

Rate each item below according to how well you think these statements describe you.

(Utilize a 9-point scale: "never true of me" 1 2 3 4 5 6 7 8 9 "always true of me"; 0 = "Prefer not to say"):

I am a nurturing person
I am a self-sufficient person
I am understanding
I make my own choices
I am a compassionate person
I am my own person
I am self-reliant
I am sympathetic
I am sensitive to the needs of others
I am an independent person

Computer Proficiency

Indicate the extent to which you agree with the following statements

(Utilize a 7-point scale of “strongly disagree 1 2 3 4 5 6 7 strongly agree; 0 = “Prefer not to say”):

I am highly competent at...

... creating and editing documents in a word processor
... creating and maintaining electronic spreadsheets of data
... creating and maintaining data tables & records in a database progra
... sending and receiving email messages
... searching for information utilizing a Web search engine (like ‘Google’)

Web Skill Test

Which of the following have you done? (Check all that apply)

- Ordered a product / service from a business, government or educational entity by filling out a form on the web
- Made a purchase online for more than $100
- Created a Webpage
- Customized a Webpage for yourself (e.g. MyYahoo, CNN Custom News)
- Changed your browser’s “startup” or “home” page
- Changed your “cookie” preferences
- Participated in an online chat or discussion (not including email)
- Listened to a radio broadcast online
- Made a telephone call online
- Used a nationwide online directory to find an address or telephone number
- Taken a seminar or class about the Web or Internet
- Bought a book to learn more about the Web or Internet
- Did Internet banking
- Prefer not to say

Technology Comfort

How comfortable do you feel using computers, in general?

Very comfortable
Somewhat comfortable
Neither comfortable nor uncomfortable
Somewhat uncomfortable
Very uncomfortable
Prefer not to say

How comfortable do you feel using the Internet?

Very comfortable
Somewhat comfortable
Neither comfortable nor uncomfortable
Somewhat uncomfortable
Very uncomfortable
Prefer not to say

How satisfied are you with your current skills for using the Internet?

Very satisfied - I can do everything that I want to do
Somewhat satisfied - I can do most things I want to do
Neither satisfied nor unsatisfied
Unsatisfied - I can't do many things I would like to do
Very unsatisfied - I can't do most things I would like to do
Prefer not to say

Frequency of Accessing the Web from Different Locations

From home (including a home office)

Daily
Weekly
Monthly
Less than once a month
Never
Prefer not to say

From work:

Daily
Weekly
Monthly
Less than once a month
Never
Prefer not to say

From school:

Daily
Weekly
Monthly
Less than once a month
Never
Prefer not to say

From public terminals (e.g., a library terminal, public kiosk):

Daily
Weekly
Monthly
Less than once a month
Never
Prefer not to say

From other places:

Daily
Weekly
Monthly
Less than once a month
Never
Prefer not to say

Connection to the Internet

Which of the following connection speeds do you primarily use to connect to the Internet? (Round to the closest value if necessary.) If you access the Internet at home via a commercial provider, choose the speed from you to your Internet provider:

Regular dial-up (through your phone company)
DSL low-speed (through your phone company)
DSL high-speed (through your phone company)
Cable (through your cable provider)
Do not know
Prefer not to say

Number of personal computers

How many personal computers are in your household (including laptops, but not including electronic organizers)?:

0
1
2
3 or more
Prefer not not say

Perceptions of Web-based Information Seeking*(taken fromFord & Miller, 1996)*

Rate each item below according to how well you think these statements describe you.

(Utilize a 5-point scale: “strongly agree” 1 2 3 4 5 “strongly disagree”; 0 = “Prefer not to say”)

- I usually only look at things on the Internet that have been suggested to me.
- Despite its complexity, I generally manage to find my way around the Internet fairly effectively.
- I rarely find anything useful on the Internet.
- I usually manage to keep ‘on target’ and avoid too much irrelevant material when using the Internet.
- I’m prepared to plough through quite a lot of irrelevant information in case there’s something useful I might otherwise miss on the Internet.
- If I had to choose only one, I’d prefer keyword searching to browsing (hypertext) on the Internet.
- The Internet is too unstructured for my liking.
- I personally think that the graphical elements of the World Wide Web (i.e., pictures, icons, graphics, etc. as opposed to just text) make me much more likely to use the Internet than if it were just text-based.
- When I use the Internet, I feel as though I’m not as ‘in control’ as I would like.
- My advice to someone like me would be: The best way to learn to use the Internet is to explore everything broadly to get a comparative ‘feel’ of the various aspects/tools before getting down to mastering one in any depth.
- I tend to get lost when using the Internet.
- It’s best to use the Internet only when you have a well-defined plan (rather than just browsing around).

APPENDIX B: THE TASK SURVEY

Perception of task importance

For you personally,

1. How important is it to do this task online?
   “not important at all” 1 2 3 4 5 6 7 8 9 “very important”
2. How useful is it to do this task online?
   “not useful at all” 1 2 3 4 5 6 7 8 9 “very useful”
3. How critical is it do this task online?
   “not critical at all” 1 2 3 4 5 6 7 8 9 “very critical”

Attitude towards a particular task

4. I have positive feelings towards doing this task online.
   “strongly disagree” 1 2 3 4 5 6 7 8 9 “strongly agree”
5. The thought of doing this task online is appealing to me.
   “strongly disagree” 1 2 3 4 5 6 7 8 9 “strongly agree”
6. It is a good idea to be able to do that task online.
   “strongly disagree” 1 2 3 4 5 6 7 8 9 “strongly agree”

Chapter 1.8

A Proposed Template for the Evaluation of Web Design Strategies

Dimitrios Xanthidis
Ciber, University College London, UK, DEI College, Greece, & NYC College, Greece

David Nicholas
Ciber, University College London, UK

Paris Argyrides
University College London, UK

ABSTRACT

This chapter is the result of a two years effort to design a template aiming at standardizing, as much as such a task is feasible, the evaluation of Web sites. It is the product of a few publications in international conferences and journals. A thorough review of the international literature on the subject led the authors to conclude there is a very large number of opinions, thoughts and criteria from different professionals involved, directly or indirectly, with the process of designing a good Web site. To make matters even more complicated there are a number of different terms used by various scholars, scientists and professionals around the world that often refer to similar, if not the same, attributes of a Web site. However, it seems that all these differences could boil down to a systematic approach, here called evaluation template, of 53 points that the design strategies of the Web sites should be checked against. This template was tested on a significant number (232) of Web sites of Greek companies and proved it can be used to evaluate the quality of Web sites not only by technology experts but by non-experts alike. The evaluation template, suggested here, is by no means the solution to the problem of standardizing the process of evaluating a Web site but looking at other work done on the subject worldwide it is a step ahead.

DOI: 10.4018/978-1-60566-100-1.ch014

INTRODUCTION

Despite the fact that in many developing countries internet access and e-commerce was not introduced until very recently (Xanthidis and Nicholas, 2004), the world is, clearly, moving towards the digital platform (Figure 1 – Greece in the red circle) with a rapidly increasing number of companies in these countries hosting Web sites. The question is whether these Web sites meet the international standards concerning a site's functionality. A preliminary research of large on- or off-line universities' libraries and governmental Web sites revealed that there are a number of different professions involved in the process of designing a good Web site, e.g. managers, marketing people, information technology experts, lawyers, ethnologists, all having different opinions regarding the functionality and appearance of a good Web site. However, it also proved it is possible to design a template that incorporates the main points of all these different views.

A critical parameter affecting the way people interact with a Web site is its structure, overall design and layout. A poorly designed Web site might lead to accessibility problems as well as reduced interest to navigate through it causing reluctance to visit the site again. Even though professional firms design many Web sites, there is, still, a substantial amount of work done by people with limited knowledge on how a well-designed Web site should be regardless of the fact these technology experts have the know-how to build any e-commerce solution, from a simple to a very sophisticated one.

The main problem in most cases where an evaluation of a Web site is required is the lack of certain systematic methodology to follow. This is exactly what this chapter is all about. A simple yet comprehensive, straightforward yet seen from four different angles, approach of how a Web site could be evaluated based on a number of criteria gathered from many different sources, scholars, scientists and academics, worldwide. Noone can claim to have found the solution to a problem so complex that it involves a variety of different professions not limited to the information and telecommunications technology. However, the discussion that this template has be subject to in three international conferences leads the authors that it is, indeed, a small step ahead toward the solution to the problem.

BACKGROUND

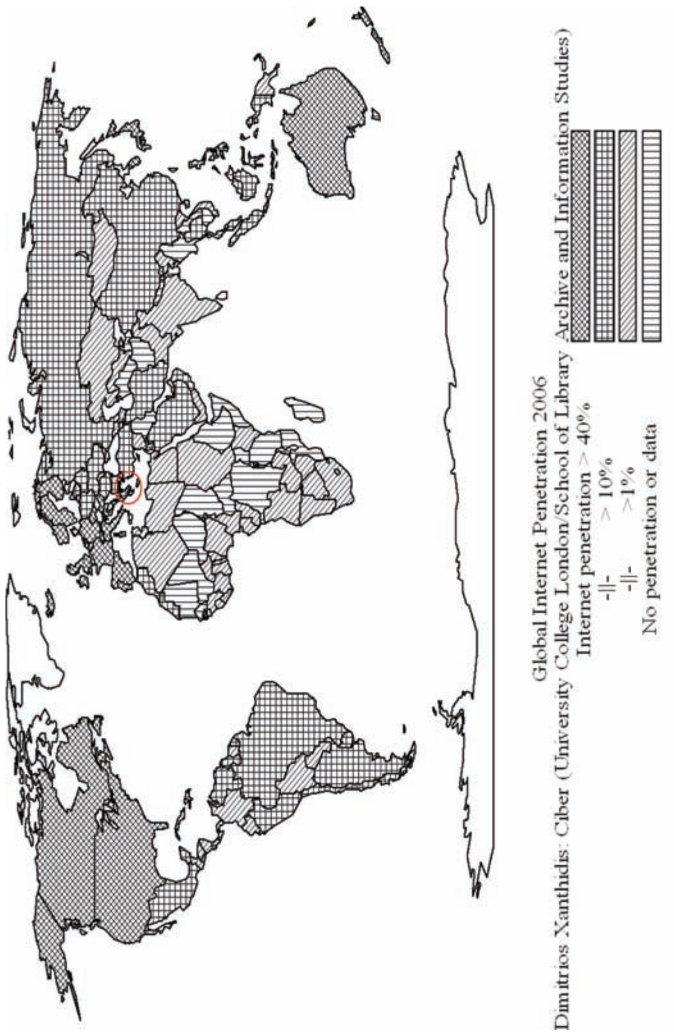
In a highly competitive environment, such as the Web, with billions of sites online and thousands added every day (D-Lib Magazine, 2003) designers/developers consider important that Web sites are attractive and inspire trust to the users so as to cause them to revisit. Therefore, once decisions have been made as of what features and functionalities the e-commerce solution should include the technology experts come into play in order to realize the solution into a good Web site. Based on extensive review of the international literature four categories of features and functionality are considered key for the successful implementation of an e-commerce strategy: user-interface design, globalization and customization, accessibility and availability, security and privacy. This section identifies, describes and analyzes the issues that comprise each category.

Stickiness

In the internet, billions of Web sites exist and even thousands are added every day (Trends…, 2003; Faster…, 2002). Designers and developers consider it important that their Web sites be attractive and inspire trust in users. This is reflected by the amount of time repeatedly spent visiting a site; a practice known as stickiness, a combination of "content, usability and personalization" and other issues, each one to be evaluated and measured on its own merit (Stickiness…, 2000).

Arguably the most important element of a Web site's attractiveness is its graphical user interface (GUI). The user interface should contain a mixture of graphics and text that could make it "appropriate" and "appealing" to any visitor

Figure 1. Global Internet penetration 2006



(Sutcliffe, 2002). Furthermore, Nielsen (1999) supports the assumption that the actual Web site content is among its most important attributes. This can be accomplished by avoiding annoying and distracting elements i.e. banners, marquees, graphics that "overshadow text", also the "overuse of animations", or unusual designs which do not follow certain accepted patterns of Web site design, etc (California, 2002; Interface…, 2002).

Another important guideline to follow when implementing a Web site is to avoid using scrolling mechanisms (Interface…, 2002). The reason is it has been proven that the user, usually, ignores hyperlinks difficult to be seen (Zhang *et al.*, 2000; Iowa, 1999). Several techniques are available to avoid such a negative aspect but two are the most popular among Web developers. The implementation of floating hyperlinks, i.e. hyperlinks that are programmed in such a way as to "follow" (floating on screen) the active/visible part of the particular Web page, is one of them. Another way is to limit the content of a Web page to that which can fit in one screen shot.

Regarding hyperlinks the Web developers should also be concerned with their placement and style. They should be easily accessible at a glance, and readable with their font preferences and their style not causing stress to the user when trying to distinguish them from other content. In case icons are used instead of text as hyperlinks, these should be, intuitively identifiable at least by information and communications experts, business people and marketing professional, if not everyone (Zhang *et al.*, 2000; California, 2002). These are simple human-computer interaction guidelines that apply in the case of Web sites as well.

One of the essential requirements for every Web site is to avoid having undefined objects as the targets of any of its hyperlinks, meaning that none of the hyperlinks should lead to a missing or dead link. Also the content of the target object of the hyperlinks should be relevant to the Web site's content (Helm, 2001; Internet…, 2002; California, 2002). The opposite could seriously damage the image of the company the Web site belongs as it would cause the visitor's lack of trust to the company severely reducing the chances to succeed in the e-commerce arena.

A very useful feature of every Web site is the implementaion of a site map of some sort. The reason for that is every user would like to know their location at any depth in the Web site they are surfing. For this purpose it would be useful if such mechanisms as site tree diagrams, composed of text or icon hyperlinks, were included displaying the user's location (Roy *et al.*, 2001; California, 2002). Not doing so will most likely cause time loss and tiredness from the part of visitor and, consequently, reluctance to revisit the site.

Another quite handy element of a Web site implemented all too often recently is the internal search engine. It is strongly recommended by technology experts that any Web site that includes articles or any type of information of significant size and/or value should either have this feature implemented or at least contain hyperlinks to the complete text if available (Nielsen, 1999). This trend was followed in the past by online newsgroups, journals and the like (Zhang *et al.*, 2000) but the newly developed Web sites, especially those that belong to large organization, incorporate this feature as well. Its advantage is that it radically reduces the time needed to find the things that one is looking for in the site adding positive points to the company's overall e-commerce strategy.

A critical element, often overlooked, of the quality of a Web site is the quality of information it provides to its visitors. The information displayed should be extracted from the most accredited and accurate source (Zhang *et al.*, 2000). Additionally, it should be updated regularly to eliminate the possibility of any outdated content, product specifications or "past-due elements" (Kateratanakul and Siau, 1999). Otherwise, failure to comply with the aforementioned criteria will cause a direct impact on the consumer's behavior towards the corporation i.e. misbelief of the information presented (Katerattanakul and Siau, 1999).

Finally, a very easily implemented feature with surprising positive influences on the visitors' behavior is any mechanism that would allow for visitor feedback. A Web site should allow visitors to comment on its strengths and weaknesses (Zhang *et al.*, 2000) as well as provide a two-way communication channel (Katerattanakul and Siau, 1999), by means of online surveys, e-mail link, feedback forms (Interface…, 2002; Evaluating…, 2004). It would help the visitor feel that it's ideas, comments, remarks are important and taken seriously under consideration.

Customization and Globalization

A Web site's success depends not only on features such as the aforementioned, but also on its global (or local) perspective, meaning its attractiveness and usefulness to populations in different geographic regions, a feature often referred to as globalization. The reason is people in different parts of the globe behave in different ways to various stimulations triggered by a Web site because they live in different cultures, practice different religions and communicate using various languages and symbols (Hanrahan and Kwok, 2001). Furthermore, it would be quite helpful to clarify, through the Web site, legal and/or customs particularities that might affect a visitor's engagement in e-commerce activity when using the Web site of a company based in another country than the one the individual resides. This factor could cause positive first impressions to some populations or culture shock to others. Therefore, the strategy followed in designing the site should address whole populations (Rutherford, 2000).

In order to achieve the above a Web designer/developer has to take under consideration certain realities. First, it is a false assumption that English is the internet's dominant language. Indeed several studies and surveys reveal other languages are used more by the internet users (Xanthidis and Nicholas, 2004; Communicate…, 2000). A company that wishes to attract multilingual audiences should include them in their e-commerce strategy as alternative target audience in addition to the English speaking internet users (Hanrahan and Kwok, 2001). Then, the color used for the background is another issue that affects users' positive or negative reactions. Recent surveys revealed that different colors have different connotations for different regional populations (Zhang *et al.*, 2000; Hanrahan and Kwok, 2001). One such example is the case of China where red is the dominant color (Anderson and Fell, 2003) and has several meanings including the symbolism that the person whose name is written in red is dead, or about to die, or on the other hand expresses such happy moments of life as birthdays, weddings etc. and in general is considered good luck.

A third key point to seriously consider when developing a Web site with global prospects is that users should also be informed about the legal framework related to taxation and import/export procedures in case products are to move in or out of a country (Rutherford, 2002). The reason for that is it is not rare to have sanctions imposed to a country from the part of the international community or have the a ban on certain products from the part of a country's government. Finally, online ordering forms should include a "universal address" format i.e. instead of using the U.S. term "zip codes" use the universal "postal codes" (Housley, 2004), and allow for the selection of various countries and their corresponding addresses.

On the other hand, the developer must address each individual's preferences as well. This is called customization or "adaptive interfaces" (Ardissono *et al.*, 2002) and refers to a Web site's built-in facility to identify a user's preferences even before any interaction takes place between the user and the site and present information in a way that is tailored by the users' preferences (Svet, 2003) and knowledge. Some scholars, scientists, professionals and generally experts in the field use the term personalization instead of customization. Most of the times they mean the same functionalities and just occasionaly they distinguish the two referring to the former when focusing in Web site content and to the latter when focusing in Web site interface and design. These variations in the way a Web site appears or as of the content presented to different user profiles can be created using forms, queries, cookies or other mechanisms and stored in databases.

A few added features could yield some more positive points towards achieving personalization and/or customization. For example, the different payment options accepted i.e. credit cards, money orders, various types of checks, etc., should be listed somewhere and a detailed description of the specific procedures followed both by the visitor and prospect customer of the company and by the representatives should be provided (Hanrahan and Kwok, 2001; Housley, 2004). Also, a currency converter should be implemented to facilitate quick conversion between currencies (Housley, 2004; Hanrahan and Kwok, 2001). These are very easily implemented features and quite useful helping visitors' decision towards engage in e-commerce transaction but are, once again, quite often overlooked.

Requirements, Accessibility

The introduction of new types of electronic devices such as personal digital assistants (PDAs), new generation mobile phones, also called cellular phones, with embedded internet capabilities, etc., in addition to the personal computers and laptops (notebooks) all having different abilities of presenting content to their user has lead the companies to find ways to make their Web sites available to different platforms and operating systems. The advent of mobile commerce in several digital economies worldwide has just stressed this need even further.

The main problem to be tackled is that a Web site display is primarily hardware/software dependent. Imagine the enormous problems that arise when a Web site designed in 1200x1600 in 32-bit color is viewed in the 120x240, 256-color display of a PDA or a mobile phone. It would, simply, be unreadable. In order to address this issue professionals suggest the design of a Web site that is available and its content prenentable by any type of electronic device. Currently, it appears that there are no tools available that actually convert a Web site's layout for different device usage but there are tools that help create accessible code [Macromedia…, 2004; Bohman, 2003; Sullivan, 2004). The recommended way of dealing with platform diversity is to separate layout design and content by having different layout templates, or "style sheets" for the same content, depending on the specific device (Nielsen, 1999; Accessibility…, 2004).

Closely related to the type of electronic device, the operating system and the browser platform, but mainly to the internet connection speed available is the time required for a Web page of a Web site to be loaded. This is a crucial factor when evaluating the Web site. Slow response speed, i.e. the time required to load a page inside a Web site, of more than 7-10 seconds, could be annoying (California, 2002) and discourage internet users to revisit.

No doubt the biggest challenge for every Web site designer/developer is to implement it in such a way as to make it accessible for persons with disabilities. A Web site should be designed not only with the media through which it is viewed in mind but its viewers as well. People with disabilities such as limited vision, hearing or mobility could find it difficult to navigate in a site filled with "graphically intense" content i.e. fairly large amounts of different colors and graphics. Too much color could be a problem for a person who is "visually impaired" person since it may make the content hard to read (Universal…, 2004). For that reason it is suggested to host a second or even third version of the Web site, customized for persons with disabilities (McManis *et al.*, 2001).

There are a number of guidelines to follow for versions of Web sites for viewers with various types of disabilities. The first is that if tables are used in which text is contained, then a logical grouping must be followed since most screen readers and magnification software may not read the text correctly. Text in cells must be separated into paragraphs to assist reading software (Making…, 2002; Pyatt, 2004). Additionally, include the functionality of providing textual description of images and "non-textual elements" in the case where browsers are configured not to display images, or the person who is using the browser uses a screen reader that cannot "read" images (Making…, 2002).

In the most likely event that a Web site includes "motion and animation" this should be at a frequency of less than 2Hz or more than 55Hz, as within this frequency range an animation may "trigger epileptic seizures" to individuals with related health problems (Making…, 2002; 30; Iowa, 1999). Finally, it would be quite useful to ensure that the site contains a mechanism that may trace the utilization of a screen reader or any other related tool and/or has also the ability to identify a change in language and adjust accordingly (Making…, 2002).

Some other issues related to accessibility and availability are the following:

- Text that is available through JavaScript i.e. pop-up windows, should also be available for users with JavaScript disabled and for users utilizing screen readers since screen readers may not read text contained in JavaScript (Pyatt, 2004).
- Frequently Asked Questions (FAQ) should be implemented together with a Help Topics feature. Accessibility covers matters that deal with user problems, not just hardware. Online guides, help topics and support reduce user stress to solve potential problems and increase the ease of navigating the Web site (Roy et al., 2001).

The main problem with the implementation of the features mentioned just above is the overall costs associated with it both in terms of time but most important in terms of money. To make matters worse the returns of investment are far from sufficient enough as the internet users' population that would be addressed by such sophisticated sites is a very small part of the overall online population. This is the main reason even large multinational corporations are reluctant in realizing such types of Web sites despite the various directives towards this goal from government organizations or nations like the European Commission and the U.S. department of Justice just to name a couple.

Security, Privacy, Legal and Ethical Issues Involved in Internet Marketing

Security, privacy, legalities and ethics are probably the most discussed technologies issues, nowadays. Several studies were conducted to clarify how they affect large corporations' successful or failed strategies to attract digital consumers (Privacy…, 2002). Currently, the most effective way to tackle this problem is to apply available mechanisms, in the form of software packages, aiming to protecting and securing valuable and sensitive data and restricting access to vulnerable systems (Benjamin *et al.,* 1998).

Unfortunately, it is a proven fact that there is no bulletproof mechanism to ensure complete defense against the various types of threats e.g. spyware, viruses including Trojan horses among other malicious programs/scripts, adware, even cookies used improperly by unauthorized people, etc. Then, it is on the developer's judgment to decide which of the available mechanisms should be used and how to ensure the success of internet strategies without compromising their visitors' privacy and keeping security, legal and ethical issues properly addressed. This is a goal very difficult to achieve. On one hand the more visitors' data a company keeps recorded the more effectively it will present a customized Web site tailored to their needs. On the other hand this causes many compromises in terms of the visitors' personal privacy and quite possibly of their personal computer security from malicious software. The following guidelines address the majority of these issues except all those that are not directly connected to the Web e.g. television/radio marketing.

First, in order to ensure the visitor's privacy Web sites should not collect sensitive information from users' PCs without their consent. In those cases where it is decided as necessary to collect such information the visitors should be clearly informed as of the use of the information. Personal data is most often collected through the use of cookies, spyware, and other related mechanisms. It is not always possible to directly confirm existence of such mechanisms like spyware and computer viruses. However, there are a number of anti-spyware and anti-virus software available which can be used by internet users to quite successfully block any attempts to compromise their personal computers' security and their own privacy.

Second, aiming to further protect visitors' personal financial data e-commerce Web sites at the transaction level (Xanthidis and Nicholas, 2007) should implement security protocols and services, like SSL (Secure Socket Layer), SET (Secure Electronic Transaction) to name the most widely used, to ensure safe transactions over the

Internet (Verisign, 2002). Furthermore, in those cases where e-mails are exchanged between the company's representatives and their Web site's visitors it could help if the latters' e-mail addresses were protected or masked via some type of scripts, forms, buttons, etc. to help defend against spam bots' attempts to identify e-mail addresses while crawling the Web.

Looking from the opposite site that of the owner of the Web site things are a little more complicated in those cases where the site is somehow connected with the company's intranet. In that case, the company's information and communication technology experts must ensure that no unauthorized person is allowed to enter Web pages restricted to authorized access. This could be achieved by implementing log-in procedures to authenticate a visit to such pages.

Finally, in every Web site like in every other software a message should be present to inform the reader that the material is an official document bound by relevant international copyright laws (Fishman, 1994).

METHODOLOGY

The aim of this work was to develop a systematic methodology for the evaluation of Web sites which would be as simple as possible yet comprehensive enough to include all those elements discussed in the previous section with straightforward answers while the evaluation takes place. The authors, then, came up with an evaluation template which comprises of 53 questions divided, not equally, into four categories called dimensions each one tackling the issues discussed earlier. It was also decided to use only dichotomous questions and avoid all other types, i.e. multiple answer, semantic differential, likert scale valued, ranked ordered. The rationale behind this decision is the idea to have a template as binary in nature as possible, one that any individual could use, even not having a significant technology background, limiting subjective judgement as much as possible. Also, the authors wanted to design in a way to make the evaluation of any Web site, no matter how large or complicated, quite feasible as of the time required. The results can be seen in the next four tables (see Table 1, Table 2, Table 3, Table 4).

In order to test the template the authors selected for evaluation a quite significant in size sample of the Web sites of 232 medium-large companies from the 15 sectors of the Greek economy, public and private, either "local" (Greek) or international with subsidiaries in the country (see Appendix). It took between 15' and 20' to evaluate each site and the evaluation period started on 11/5/2005 and ended on 30/6/2005. The answers to the evaluation questions were quite straightforward, binary in nature, a fact that simplified the process. In several cases during the evaluation, i.e. appropriate and appealing, we found it was somewhat subjective to determine/measure the Web site but in broad lines our decision was in general agreement with what any person would value as an appropriate and appealing Web site. This holds true despite the fact that people coming from different backgrounds may view this issue under another perspective.

One aspect we found to be problematic was the measurement of the *time availability* of a Web site. This would be possible by monitoring the site's online status on a 24/7 basis or alternatively by examining a detailed specification and possible the logs files of the hosting server. Human resource and time constraints of this part of the study prohibited us from doing the first. Furthermore, the fact that the server and network specifications and/or their log files were not available to us did not permit to follow the second path.

ANALYSIS AND RESULTS

Web Site Design/Stickiness

Initially, concerning Web site design issues, the study showed that developers in Greece follow

Table 1. Evaluation template: Dimension I: Stickiness

1.	Lack of tendency to use scrolling mechanisms.		Yes = 1	No = 0
2.	Hyperlink placement/style			
	i.	Hyperlinks easily accessible (at a glance)?	Yes = 1	No = 0
	ii.	Presence of floating hyperlinks (embedded in bars)?		No = 0
	iii.	Font properties (name, size, bold/no bold, color) of the text hyperlinks distinguishing them from the rest of the text?	Yes = 1	No = 0
	iv.	Icons used in graphical type hyperlinks intuitively identifiable, i.e. do they represent the target object or are they misleading?	Yes = 1	No = 0
3.	Hyperlink target/content			
	i.	Tendency NOT to have dead hyperlinks in the site (use home page)?	Yes = 1	No = 0
	ii.	Hyperlinks lead to relevant pages?	Yes = 1	No = 0
4.	Site maps			
	i.	Presence of any type of site map, i.e. site tree diagram, drop-down menus, etc.?	Yes = 1	No = 0
	ii.	Mapping mechanisms informative as to the actual depth in which the user navigates?	Yes = 1	No = 0
5.	Web site user interface attractiveness			
	i.	Appropriate and appealing?	Yes = 1	No = 0
	ii.	Lack of distracting and annoying elements?	Yes = 1	No = 0
6.	Information quality and completeness			
	i.	Any "read more" hyperlinks available clarifying possibly broad, unclear or unknown topics to the reader?	Yes = 1	No = 0
	ii.	Is the information provided in the Web site signed and, thus, credible?	Yes = 1	No = 0
	iii.	Is the information provided updated on a reasonably expected timeliness?	Yes = 1	No = 0
	iv.	Any internal search engine available?	Yes = 1	No = 0
7.	Visitor's feedback enabled and online help available			
	i.	E-mail links available to the visitors?	Yes = 1	No = 0
	ii.	Online surveys available?	Yes = 1	No = 0
	iii.	Feedback forms available?	Yes = 1	No = 0
	iv.	On line help available (e.g. FAQs, etc.)?	Yes = 1	No = 0

the internationally accepted standards of what a nice looking Web site should be like (Figure 2). Indeed, the majority of developers (142/232; 61.21%) tend to avoid the use of scrolling mechanisms which proved to have a negative impact in the Web site's attractiveness. In all but 3 cases (229/232; 98.7%) the hyperlinks were found to lead to relevant pages and in all but 6 (226/232; 97.4%) the hyperlinks did not lead to a dead end. If icons are used to represent the hyperlinks, the selections were found to be intuitively identifiable in 216/232 cases (93.1%). When text was the basis for the hyperlinks, the font properties were quite helpful in distinguishing it from the rest of the objects on the Web sites in 204/232 of the cases (87.9%). In general, the hyperlinks could be found easily at a glance in 167/232 of the cases (71.9%).

Concerning the presence of any sort of distracting and annoying elements, findings were quite positive again as in 212/232 cases (91.3%) no such elements were found and in general the user interface of the Web sites was found to be appropriate and appealing in 215/232 cases (92.6%). The only problem related to site interface was that in the majority of the Web sites floating hyperlinks

Table 2. Evaluation template: Dimension II: Customization and globalization

1.	Languages supported (cocacola.com is worldwide)			
	i. English		Yes = 1	No = 0
	ii. Spanish		Yes = 1	No = 0
	iii. Chinese		Yes = 1	No = 0
	iv. French		Yes = 1	No = 0
	v. German		Yes = 1	No = 0
	vi. Other (Greek, Turkish, Arabic, Hebrew, Japanese, etc.)		Yes = 1	No = 0
2.	Colors used: Is Web site color related with the cultural background (Western, Asian, etc) of the targeted population?		Yes = 1	No = 0
3.	Issues related to globalization			
	i. Briefing/information provided concerning import/export and taxation issues?		Yes = 1	No = 0
	ii. Any restrictions applicable for a commodity to be exported/imported to/from certain countries?		Yes = 1	No = 0
	iii. Any list of countries to which import/export restrictions apply?		Yes = 1	No = 0
	iv. Any information provided about available shipping/ delivery options?		Yes = 1	No = 0
4.	Level of customization the Web site achieves			
	i. Level 0: No customization		Yes = 1	No = 0
	ii. Level 1: Content → display information based on previous user interaction and preferences stored in log files.		Yes = 1	No = 0
	iii. Level 2: Suggestive → display information on relevant or competitive commodities/services.		Yes = 1	No = 0
	iv. Level 3: Informative → display further clarifications on issues not in the sphere of the user's knowledge.		Yes = 1	No = 0
	v. Level 4: Design format → lets the user permanently decide the layout of the Web site as it appears in his/her browser.		Yes = 1	No = 0
	vi. Level 5: Language and Culture → identifies the user's of language and culture preference based on the IP address of the user's system or on the user's selection of a region/country from a map/list available.		Yes = 1	No = 0
5.	Payment – shipping/billing options			
	i. List of different payment options available?		Yes = 1	No = 0
	ii. Detailed description of each payment option available?		Yes = 1	No = 0
	iii. Currency converter available?		Yes = 1	No = 0
	iv. Use of the universal "postal code" instead of the regional "zip code"?		Yes = 1	No = 0

were not present (152/232; 65.5%).

The problems started when more technical details were evaluated (Figure 3). One of the central components of any Web site, the site map, was only found in 85/232 (36.6%) of the Web sites. More technical mapping mechanisms that could provide information as of the depth in which the visitor navigates were even more seldom utilized (10/232; 4.3%). As far as online help made available to visitors is concerned, unfortunately, such a feature was only available in one site (1/232; 0.4%). The same can be said of the availability – lack, rather – of online surveys with only 2 sites implementing such feedback mechanisms for the visitors (2/232; 0.8%).

The most surprising element of the findings, however, was that only 156/232 sites (67.2%) incorporated the very easy to implement and almost obvious to include e-mail link for the visitors and, also, less than half the Web sites (106/232; 45.6%) made a feedback form available to visitors. The information was updated quite regularly in 227/232

Table 3. Evaluation template: Dimension III: Accessibility, availability, hardware/software requirements

1.	Is the Web site accessible (Platform Compatibility)		Yes = 1	No = 0
2.	Is the Web site optimized for users with a mental or physical handicap?		Yes = 1	No = 0
3.	Hardware/ Software/ Network requirements			
	i.	Time required loading the Web site's home page?	<10" = 1	No = 0
	ii.	Web site displayed properly, i.e. no horizontal scrolling mechanisms, no twisting of objects, etc., in different display resolutions?	Yes = 1	No = 0
	iii.	Option to download and install "third party" components required to view the Web site, e.g. activeX, flash players, different fonts, etc.	Yes = 1	No = 0

Table 4. Evaluation template: Dimension IV: Security, privacy

1.	Security			
	i.	Authentication required to login into possible intranet part of the site?	Yes = 1	No = 0
	ii.	If transactional or interactive what protocol are they using (None, SSL, SET, Other)?	Yes = 1	No = 0
	iii.	What is the cipher strength?	Yes = 1	<128 = 0
	iv.	On-line anti-virus scanner available?	Yes = 1	No = 0
	v.	Web site expires after a pre-defined amount of idle time?	Yes = 1	No = 0
2.	Privacy			
	i.	Avoid the use of tracking/identifying mechanisms i.e. cookies, spyware, etc, without the consent of the user?	Yes = 1	No = 0
	ii.	Privacy statement?	Yes = 1	No = 0
	iii.	Masked e-mail addresses through scripts, forms, buttons, etc?	Yes = 1	No = 0

cases (97.8%), however, it is signed – and, hence, credible – in only 32/232 cases (13.8%). There is the projection of providing more information in 134/232 sites (57.8%) through the utilization of "read more" hyperlinks and 88/232 of those (38.0%) included an internal search engine.

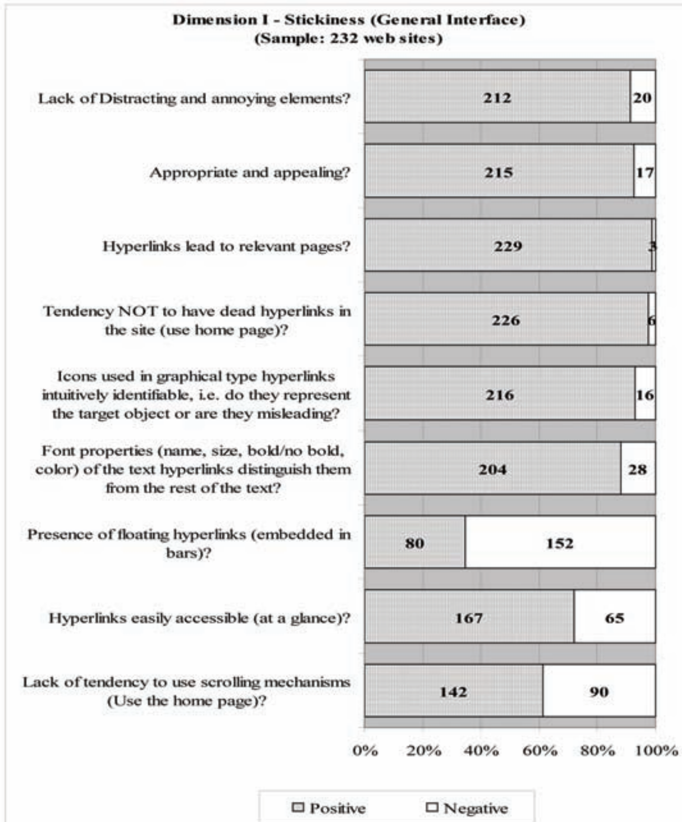
Customization and Globalization

It was quite obvious that except Greek (211/232; 90.95%), the only other language seriously considered and used when developing Web sites was English (178/232; 76.72%). All the rest, i.e. Spanish (7/232; 3.01%), French (7/232; 3.01%), German (8/232; 3.44%) and Chinese (3/232; 1.29%), included into our study, were seldom used mainly in specific cases of companies which probably had some business or other relations to certain groups of people in parts of the world.

In terms of the colors used, they were found to be appropriate (231/232; 99.57%) in connection with the populations of visitors targeted (based on the assumption that the language in which the text was written reflected the mother tongue and culture of the visitor targeted). However, it was also realized that this last conclusion was not based on enough evidence and it would be very interesting to see how things would change if, say, a large proportion of the targeted population were Chinese-speaking people.

Finally, only the executives of a handful of companies seem to take things seriously as only in 10/232 cases (4.31%) was there some kind of briefing about import/export and taxation matters, and only in 11/232 Web sites was information provided on shipping/delivery options (4.34%).

Figure 2. Web site evaluation from a technical viewpoint. Dimension 1 - Stickiness



No discussion can be made about providing lists of countries or commodities for which certain imports/exports restrictions apply (Figure 4).

Next, concerning customization features offered by the Web sites, the study showed that 89/232 (38.36%) Web sites provide no customization features whatsoever. Furthermore, no Web site was found displaying information based on previous user interaction and preferences stored in log files or in the form of cookies. A relatively significant (and rather unexpected considering the previous results) number (108/232; 46.55%) displayed information on relevant or competitive commodities/services placing those sites in the suggestive level of customization. A small percentage (32/232; 13.79%) displayed further clarifications on issues not in the sphere of the knowledge of the user (informative level). Finally, there were no Web sites found to allow changes in the format of the design, i.e. let the user permanently decide on the layout of the Web site as it appears on his/her client browser, neither did any attempt to identify the user's language and culture preferences based on the IP address of the user's system or on the user's selection of a region/country from a map/list available.

Last, as far as available payment and shipping/billing options, the general picture of the results of the study proved disappointing (Figure 5). Only 21/232 companies' Web sites (9.05%) provided a list of available payment options and just 3 of them (1.29%) described the steps to be followed for each option in some detail. The currency converter feature, often found in many international business-oriented Web sites, was present only in 3/232 (1.29%). Universal terminology for pay-

Figure 3. Web site evaluation from a technical viewpoint. Dimension 2 – Mapping and communication mechanisms – Informative structures

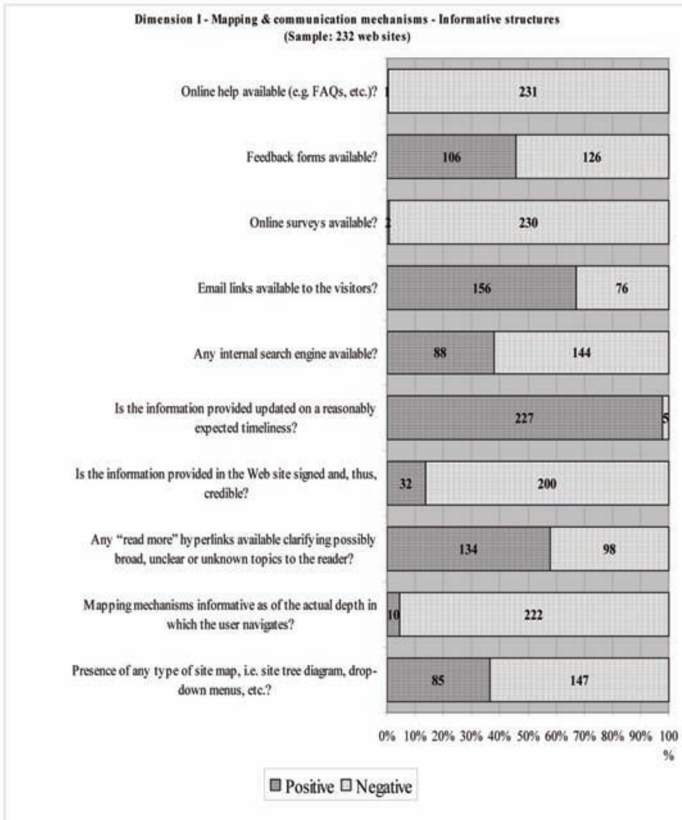


Figure 4. Information provided by the sites related to globalization issues

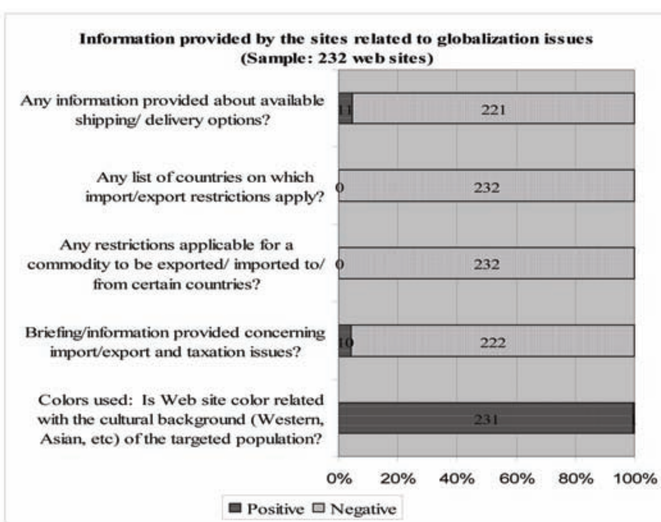

ment and shipping/delivery, e.g. the universal term "postal code" used instead of the regional term "zip code", appeared in 34/232 cases (14.66%).

Accessibility, Hard/ Software Requirements

The results of the evaluation concerning accessibility and hard/software requirements were radically different (Figure 6). In most cases (162/232; 69.83%) the sites were accessible from the common different platforms, i.e. Windows, Linux. The results were also positive when the time to load the home page was evaluated (less than 10'' was considered a reasonable time) with 214/232 (92.24%) succeeding, as well as the proper display of the page contents without object distortion or any other display anomalies under different display resolutions (226/232; 97.41%). On the negative side, unfortunately as expected, only in 1 case were the Web sites designed with the physically disabled people in mind. Also disappointing was the fact that in case third party tools were needed to run the Web pages of a Web site only in 15/232 cases (6.47%) were the options to download the respective tools given to the visitors.

Security, Privacy

The results of evaluating the Web sites with security and privacy in mind were completely disappointing (Figure 7).

On the one hand, security concerns should be tackled but very little was found be undertaken in this direction. Only 20/232 (8.62%) sites had some kind of authentication process running when a visitor requested to access to the companies'/organizations' intranet. Even less were the sites (16/232; 6.90%) protected by a security protocol like SSL, SET, etc. The cipher strength for the sites protected by such protocols was less than 128 (very low indeed) in 218/232 cases (6.03%). No on-line anti-virus scanner was available and no expiration time after a specific amount of idle time (as suggested for security purposes) was present and/or activated.

On the other hand, concerning the visitors' privacy, the study showed a tendency to avoid tracking/identifying mechanisms, like cookies, spy ware, etc. (231/232 cases; 9.57%) but there is serious doubt this was a conscious decision on the part of the companies' executives or lack of technical expertise required to implement it. Additionally, only 31/232 sites were found (13.36%) with a privacy statement (an utterly simple feature to realize), and only 56/232 (24.14%) cases of Web sites with masked e-mail addresses through scripts, forms, buttons, etc. for privacy-related reasons.

IMPLICATIONS

It is quite possible after all, although very difficult, to put together all bits and pieces that make up the puzzle of what suggests a good Web site, be it a simple one or a very sophisticated. The number of the elements to be evaluated is significant, of course, but limited enough to make the whole idea of evaluating a Web site feasible as of time and effort required. Furthermore, the nature of the questions of the template is such that allows even non-experts of the field of e-commerce to use it for their evaluation of their Web sites.

The template introduced in this chapter could be used as a "marking scheme" for the assessment of all different types of Web sites by information and communication technology (ICT) experts in a systematic way. It could also be used by business and other professionals as a suggestion, a rule of thumb indeed, of how could or should their companies' Web sites be implemented to meet their online strategies. The main reason the template can deliver both the aforementioned goals is that the questions to be answered carry on them the "correct" approaches of how to address each of the issues related to the development of a Web site. Therefore, it is quite straightforward that

Figure 5. More globalization issues faced

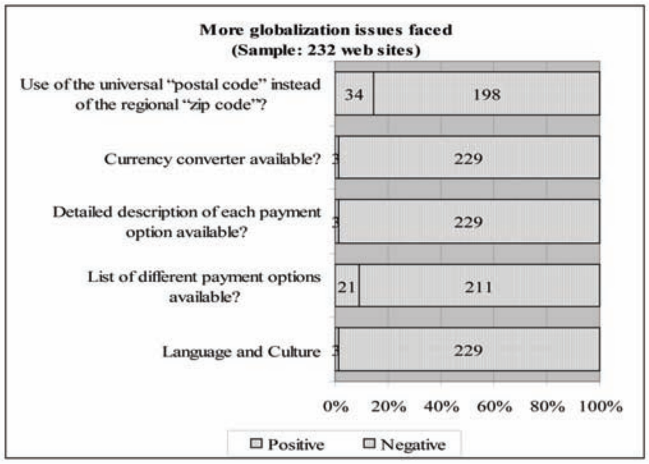

Figure 6. Accessibility and availability issues

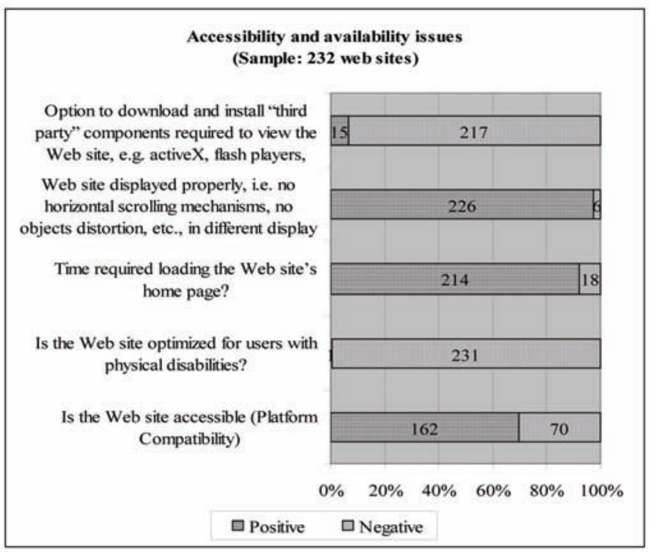
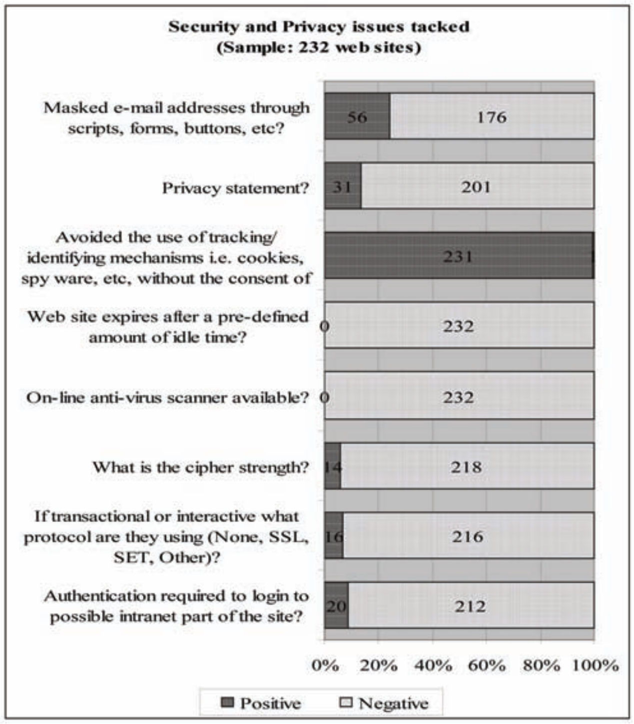


every positive answer adds one positive point to the overall design of the site with any negative answer pointing to its weaknesses.

LIMITATIONS: FURTHER RESEARCH

The authors used a number of Greek Web sites to test this systematic methodology that the suggested evaluation template represents. Despite the poor performance of the rather large local information society in e-commerce activity it was possible to use this template to draw useful conclusions for the quality of the Web sites and their effect in e-commerce growth in the country. The authors selected the Greek Web sites for reasons of physical proximity to the companies (Greek residence). However, it would be quite interesting to test the same methodology on the Web sites of companies in the developed digital economies and those of

Figure 7. Security and privacy issues tacked



the underdeveloped countries as well just to see if it is applicable in those cases as well. Also, the methodology was tested on medium-large companies' sites. It would help to see if and how much applicable it would be in the case of small companies as well.

Apparently, like in every other field of information and communications technology this effort is not over. This is only a measurement template. The next step, parallel to updating the template with new ideas and insight from professionals all over the world, is to work towards clarifying the metric against which the various results of measurement should be checked. There could be certain numerical results that distinguish a poor designed Web site from a better one and then from a very good one. Probably such a distinction is more complicated as it depends on certain variables including but not limited to the type of the Web site, e.g. information level up to full e-commerce solution, the progress towards the digital economy in the country of the company that owns the site, and others.

CONCLUSION

It should be underlined once again that the task of designing a comprehensive template/formula that could be used to evaluate Web sites looking from different viewpoints based on the various professions involved is extremely difficult, but proven feasible. The pieces of the puzzle are many and as the technology changes they change with it. However, there are a few facts that helped achieve our goal of designing the proposed evaluation template.

First, despite the quite significant, some could consider it rather large, number of 53 elements of a Web site to be evaluated they can be organized into categories each one addressing completely different viewpoints. This is the reason the authors called them dimension as it is like looking into the same structure from different angles. Second, it is proven that with just a little difficulty it is possible to answer the questions of the template in a straightforward binary way that leaves very little or no room to different and subjective interpretations of the quality of features implementing while addressing each specific issue. Third, it is proven possible to have a numerical result of the evaluation, although, by itself this cannot lead to safe conclusions as of the quality of the Web site overall but only to relevant suggestions. Finally, the time required to use this template to evaluate any Web site is very reasonable, less than 20' per site, regardless of the quality, type or size of the Web site.

The authors do not claim they found the ideal solution to the problem. What was proposed in this chapter is the result of the ongoing process of reviewing, adjusting and incorporating different ideas and thoughts into a template as little technical as possible in order for anyone to be able to use it even if that person is not an ICT expert. The authors opened a path which they believe could lead to a systematic way of assessing the quality of Web sites. The thing that encourages them to move further this type of research is the positive and insightful comments received in the conferences where this methodology is presented.

Chapter 1.9

A Review of Methodologies for Analyzing Websites

Danielle Booth
Pennsylvania State University, USA

Bernard J. Jansen
Pennsylvania State University, USA

ABSTRACT

This chapter is an overview of the process of Web analytics for Websites. It outlines how visitor information such as number of visitors and visit duration can be collected using log files and page tagging. This information is then combined to create meaningful key performance indicators that are tailored not only to the business goals of the company running the Website but also to the goals and content of the Website. Finally, this chapter presents several analytic tools and explains how to choose the right tool for the needs of the Website. The ultimate goal of this chapter is to provide methods for increasing revenue and customer satisfaction through careful analysis of visitor interaction with a Website.

INTRODUCTION

Web analytics is the measure of visitor behavior on a Website. However, what kind of information is available from Website visitors, and what can be learned from studying such information? By collecting various Web analytics metrics, such as number of visits, visitors, and visit duration, one can develop key performance indicators (KPIs) – a versatile analytic model that measures several metrics against each other to define visitor trends. KPIs use these dynamic numbers to get an in-depth picture of visitor behavior on a site. This information allows businesses to align their Websites' goals with their business goals for the purpose of identifying areas of improvement, promoting popular parts of the site, testing new site functionality, and ultimately increasing revenue. This chapter covers the most common metrics, different methods for gathering metrics, how to utilize key performance indicators, best key practices, and choosing the right Web analytics tool.

The first section addresses metrics, information that can be collected from visitors on a Website. It covers types of metrics based on what kind of data is collected as well as specific metrics and how they can be utilized. The following section discusses

DOI: 10.4018/978-1-59904-974-8.ch008

the two main methods for gathering visitor information -- log files and page tagging. For each method, this section covers the advantages and disadvantages, types of supported information, and examples for data format. Following this is a section on how to choose the key performance indicators (KPIs). This includes outlining several business strategies for integrating Web analytics with the rest of an organization as well as identifying the type of Website and listing several specific KPIs for each site type. The following section provides the overall process and advice for Web analytics integration, and the final section deals with what to look for when choosing analytics tools as well as a comparison of several specific tools. Finally, the conclusion discusses the future of Web analytics.

METRICS

In order to understand the benefits of Website analysis, one must first understand metrics – the different kinds of available user information. Although the metrics may seem basic, once collected, they can be used to analyze Web traffic and improve a Website to better meet its overall goals. According to Panalysis (http://www.panalysis.com/), an Australian Web analytics company, these metrics generally fall into one of four categories: site usage, referrers (or how visitors arrived at your site), site content analysis, and quality assurance. Table 1 shows examples of types of metrics that might be found in these categories.

Although the type and overall number of metrics varies with different analytics vendors, there is still a common set of basic metrics common to most. Table 2 outlines eight widespread types of

Table 1. Metrics categories (Jacka, n.d.)

Site Usage	Referrers	Site Content Analysis	Quality Assurance
• Numbers of visitors and sessions • How many people repeatedly visit the site • Geographic information • Search Engine Activity	• Which websites are sending visitors to your site • The search terms people used to find your site • How many people place bookmarks to the site	• Top entry pages • Most popular pages • Top pages for single page view sessions • Top exit pages • Top paths through the site • Effectiveness of key content	• Broken pages or server errors • Visitor response to errors

Table 2. Eight common metrics of Website analysis

Metric	Description	Category
Visitor Type	Who is accessing the Website (returning, unique, etc.)	Site Usage
Visit Length	The total amount of time a visitor spends on the Website	Site Usage
Demographics and System Statistics	The physical location and information of the system used to access the Website	Site Usage
Internal Search Information	Information on keywords and results pages viewed using a search engine embedded in the Website	Site Usage
Visitor Path	The route a visitor uses to navigate through the Website	Site Content Analysis
Top Pages	The pages that receive the most traffic	Site Content Analysis
Referrering URL and Keyword Analysis	Which sites have directed traffic to the Website and which keywords visitors are using to find the Website	Referrers
Errors	Any errors that occurred while attempting to retrieve the page	Quality Assurance

information that measure who is visiting a Website and what they do during their visits, relating each of these metrics to specific categories.

Each metric is discussed below.

Visitor Type

Since analyzing Website traffic first became popular in the 1990s with the Website counter, the measure of Website traffic has been one of the most closely watched metrics. This metric, however, has evolved from merely counting the number of hits a page receives into counting the number of individuals who visit the Website.

There are two types of visitors: those who have been to the site before, and those who have not. This difference is defined in terms of repeat and new visitors. In order to track visitors in such a way, a system must be able to determine individual users who access a Website; each individual visitor is called a unique visitor. Ideally, a unique visitor is just one visitor, but this is not always the case. It is possible that multiple users access the site from the same computer (perhaps on a shared household computer or a public library). In addition, most analytic software relies on cookies to track unique users. If a user disables cookies in their browser or if they clear their cache, the visitor will be counted as new each time he or she enters the site.

Because of this, some companies have instead begun to track unique visits, or sessions. A session begins once a user enters the site and ends when a user exits the site or after a set amount of time of inactivity (usually 30 minutes). The session data does not rely on cookies and can be measured easily. Since there is less uncertainty with visits, it is considered to be a more concrete and reliable metric than unique visitors. This approach is also more sales-oriented because it considers each visit an opportunity to convert a visitor into a customer instead of looking at overall customer behavior (Belkin, 2006).

Visit Length

Also referred to as Visit Duration or Average Time on Site (ATOS), visit length is the total amount of time a visitor spends on a site during one session. One possible area of confusion when using this metric is handling missing data. This can be caused either by an error in data collection or by a session containing only one page visit or interaction. Since the visit length is calculated by subtracting the time of the visitor's first activity on the site from the time of the visitor's final activity, what happens to the measurement when one of those pieces of data is missing? According to the Web Analytics Association, the visit length in such cases is zero (Burby & Brown, 2007).

When analyzing the visit length, the measurements are often broken down into chunks of time. StatCounter, for example, uses the following time categories:

- Less than 5 seconds
- 5 seconds to 30 seconds
- 30 seconds to 5 minutes
- 5 minutes to 20 minutes
- 20 minutes to 1 hour
- Greater than 1 hour (Jackson, 2007)

The goal of measuring the data in this way is to keep the percentage of visitors who stay on the Website for less than five seconds as low as possible. If visitors stay on a Website for such a short amount of time it usually means they either arrived at the site by accident or the site did not have relevant information. By combining this information with information from referrers and keyword analysis, one can tell which sites are referring well-targeted traffic and which sites are referring poor quality traffic.

Demographics and System Statistics

The demographic metric refers to the physical location of the system used to make a page request.

This information can be useful for a Website that provides region-specific services. For example, if an e-commerce site can only ship its goods to people in Spain, any traffic to the site from outside of Spain is irrelevant. In addition, region-specific Websites also want to make sure they tailor their content to the group they are targeting. Demographic information can also be combined with information on referrers to determine if a referral site is directing traffic to a site from outside a company's regions of service.

System statistics are information about the hardware and software with which visitors access a Website. This can include information such as browser type, screen resolution, and operating system. It is important that a Website be accessible to all of its customers, and by using this information, the Website can be tailored to meet visitors' technical needs.

Internal Search

If a Website includes a site-specific search utility, then it is also possible to measure internal search information. This can include not only keywords but also information about which results pages visitors found useful. The Patricia Seybold Group (http://www.psgroup.com/) identifies the following seven uses for internal search data:

- Identify products and services for which customers are looking, but that are not yet provided by the company.
- Identify products that are offered, but which customers have a hard time finding.
- Identify customer trends.
- Improve personalized messages by using the customers' own words.
- Identify emerging customer service issues
- Determine if customers are provided with enough information to reach their goals.
- Make personalized offers. (Aldrich, 2006)

By analyzing internal search data, one can use the information to improve and personalize the visitors' experience.

Visitor Path

A visitor path is the route a visitor uses to navigate through a Website. Excluding visitors who leave the site as soon as they enter, each visitor creates a path of page views and actions while perusing the site. By studying these paths, one can identify any difficulties a user has viewing a specific area of the site or completing a certain action (such as making a transaction or completing a form).

According to the Web Analytics Association, there are two schools of thought regarding visitor path analysis. The first is that visitor actions are goal-driven and performed in a logical, linear fashion. For example, if a visitor wants to purchase an item, the visitor will first find the item, add it to the cart, and proceed to the checkout to complete the process. Any break in that path (i.e. not completing the order) signifies user confusion and is viewed as a problem.

The second school of thought is that visitor actions are random and illogical and that the only path that can provide accurate data on a visitor's behavior is the path from one page to the page immediately following it. In other words, the only page that influences visitor behavior on a Website is the one they are currently viewing. For example, visitors on a news site may merely peruse the articles with no particular goal in mind. This method of analysis is becoming increasingly popular because companies find it easier to examine path data in context without having to reference the entire site in order to study the visitors' behavior (Web Analytics Association, n. d.).

Top Pages

Panalysis mentions three types of top pages: top entry pages, top exit pages, and most popular pages. Top entry pages are important because the first page a visitor views makes the greatest impression about a Website. By knowing the top entry page, one can make sure that page has relevant information and provides adequate navigation to important parts of the site. Similarly, identifying popular exit pages makes it easier to pinpoint areas of confusion or missing content.

The most popular pages are the areas of a website that receive the most traffic. This metric gives insight into how visitors are utilizing the Website, and which pages are providing the most useful information. This is important because it shows whether the Website's functionality matches up with its business goals; if most of the Website's traffic is being directed away from the main pages of the site, the Website cannot function to its full potential (Jacka, n. d.).

Referrers and Keyword Analysis

A referral page is the page a user visits immediately before entering to a Website, or rather, a site that has directed traffic to the Website. A search engine result page link, a blog entry mentioning the Website, and a personal bookmark are examples of referrers. This metric is important because it can be used to determine advertising effectiveness and search engine popularity. As always, it is important to look at this information in context. If a certain referrer is doing worse than expected, it could be caused by the referring link text or placement. Conversely, an unexpected spike in referrals from a certain page could be either good or bad depending on the content of the referring page.

In the same way, keyword analysis deals specifically with referring search engines and shows which keywords have brought in the most traffic. By analyzing the keywords visitors use to find a page, one is able to determine what visitors expect to gain from the Website and use that information to better tailor the Website to their needs. It is also important to consider the quality of keywords. Keyword quality is directly proportional to revenue and can be determined by comparing keywords with visitor path and visit length (Marshall, n. d.). Good keywords will bring quality traffic and more income to your site.

Errors

Errors are the final metric. Tracking errors has the obvious benefit of being able to identify and fix any errors in the Website, but it is also useful to observe how visitors react to these errors. The fewer visitors who are confused by errors on a Website, the less likely visitors are to exit the site because of an error.

GATHERING INFORMATION

How does one gather these metrics? There are two major methods for collecting data for Web analysis: log files and page tagging. Most current Web analytic companies use a combination of the two methods for collecting data. Therefore, it is important to understand the strengths and weaknesses of each.

Log Files

The first method of metric gathering uses log files. Every Web server keeps a log of page requests that can include (but is not limited to) visitor IP address, date and time of the request, request page, referrer, and information on the visitor's Web browser and operating system. The same basic collected information can be displayed in a variety of ways. Although the format of the log file is ultimately the decision of the company who runs the Web server, the following four formats are a few of the most popular:

- NCSA Common Log
- NCSA Combined Log
- NCSA Separate Log

- W3C Extended Log

The NCSA Common Log format (also known as Access Log format) contains only basic information on the page request. This includes the client IP address, client identifier, visitor username, date and time, HTTP request, status code for the request, and the number of bytes transferred during the request. The Combined Log format contains the same information as the common log with the following three additional fields: the referring URL, the visitor's Web browser and operating system information, and the cookie. The Separate Log format (or 3-Log format) contains the same information as the combined log, but it breaks it into three separate files – the access log, the referral log, and the agent log. The date and time fields in each of the three logs are the same. Table 3 shows examples of the common, combined, and separate log file formats (notice that default values are represented by a dash "-"):

Similarly, W3C provides an outline for standard formatting procedures. This format differs from the first three in that it aims to provide for better control and manipulation of data while still producing a log file readable by most Web analytics tools. The extended format contains user defined fields and identifiers followed by the actual entries, and default values are represented by a dash "-" (Hallam-Baker & Behlendorf, 1999). Table 4 shows an example of an extended log file.

There are several benefits of using system log files to gather data for analysis. The first is that it does not require any changes to the Website or any extra software installation to create the log files. Web servers automatically create these logs and store them on a company's own servers giving the company freedom to change their Web analytics tools and strategies at will. This method also does not require any extra bandwidth when loading a page, and since everything is recorded server-side, it is possible to log both page request successes and failures.

Using log files also has some disadvantages. One major disadvantage is that the collected data is limited to only transactions with the Web server. This means that they cannot log information independent from the servers such as the physical location of the visitor. Similarly, while it is possible to log cookies, the server must be specifically configured to assign cookies to visitors in order to do so. The final disadvantage is that while it is useful to have all the information stored on a company's own servers, the log file method is only available to those who own their Web servers.

Page Tagging

The second method for recording visitor activity is page tagging. Page tagging uses an invisible image to detect when a page has been successfully loaded and then uses JavaScript to send information about the page and the visitor back to a remote server. According to *Web Analytics Demystified* the variables used and amount of data

Table 3. NCSA Log comparison (IBM, 2004)

NCSA Common Log	**125.125.125.125 - dsmith [10/Oct/1999:21:15:05 +0500] "GET /index.html HTTP/1.0" 200 1043**
NCSA Combined Log	125.125.125.125 - dsmith [10/Oct/1999:21:15:05 +0500] "GET /index.html HTTP/1.0" 200 1043 "http://www.ibm.com/" "Mozilla/4.05 [en] (WinNT; I)" "USERID=CustomerA;IMPID=01234"
NCSA Separate Log	Common Log: 125.125.125.125 - dsmith [10/Oct/1999:21:15:05 +0500] "GET /index.html HTTP/1.0" 200 1043 Referral Log: [10/Oct/1999:21:15:05 +0500] "http://www.ibm.com/index.html" Agent Log: [10/Oct/1999:21:15:05 +0500] "Microsoft Internet Explorer - 5.0"

Table 4. W3C extended log file (Microsoft, 2005)

W3C Extended Log	#Software: Microsoft Internet Information Services 6.0 #Version: 1.0 #Date: 2002-05-24 20:18:01 #Fields: date time c-ip cs-username s-ip s-port cs-method cs-uri-stem cs-uri-query sc-status sc-bytes cs-bytes time-taken cs(User-Agent) cs(Referrer) 2002-05-24 20:18:01 172.224.24.114 - 206.73.118.24 80 GET /Default.htm - 200 7930 248 31 Mozilla/4.0+(compatible;+MSIE+5.01;+Windows+2000+Server) http://64.224.24.114/

collected in page tagging are dependent on the Web analytics vendor. Some vendors stress short, easy to use page tags while others emphasize specific tags that require little post-processing. The best thing to look for with this method, however, is flexibility – being able to use all, part, or none of the tag depending on the needs of the page (Peterson, 2004).

There are several benefits to using this method of gathering visitor data. The first is speed of reporting. Unlike a log file, the data received via page tagging is parsed as it comes in. This allows for near real-time reporting. Another benefit is flexibility of data collection. More specifically, it is easier to record additional information about the visitor that does not involve a request to the Web server. Examples of such information include information about a visitor's screen size, the price of purchased goods, and interactions within Flash animations. This is also a useful method of gathering data for companies that do not run their own Web servers or do not have access to the raw log files for their site (such as blogs).

There are also some disadvantages of page tagging, most of which are centered on the extra code that must be added to the Website. This causes it to use more bandwidth each time a page loads, and it also makes it harder to change analytics tools because the code embedded in the Website would have to be changed or deleted entirely. The final disadvantage is that page tagging is only capable of recording page loads, not page failures. If a page fails to load, it means that the tagging code also did not load, and there is therefore no way to retrieve information in that instance.

Although log files and page tagging are two distinct ways to collect information about the visitors to a Website, it is possible to use both together, and many analytics companies provide ways to use both methods to gather data. Even so, it is important to understand the strengths and weaknesses of both. Table 5 shows the advantages and disadvantages of log file analysis and page tagging.

The Problems with Data

One of the most prevalent problems in Web analytics is the difficulty identifying unique users. In order to determine repeat visitors, most Web analytic tools employ cookies that store unique identification information on the visitor's personal computer. Because of problems with users deleting or disabling cookies, however, some companies have moved towards using Macromedia Flash Local Shared Objects (LSOs). LSOs act like a cookie, but standard browsers lack the tools required to delete them, anti-spyware software does not delete them because it does not see them as a threat, and most users do not know how to delete them manually. Awareness is growing, however, and Firefox and Macromedia are working against LSOs and providing users with tools to delete them (Permadi, 2005).

Sen, Dacin, and Pattichis (2006) cite various other problems with log data from Websites including large data size and messy data. Problems with large data size are caused by massive amounts of traffic to a Website and also the amount of information stored in each record. Records with missing

Table 5. Log files vs. page tagging

Log Files		Page Tagging	
Advantages	*Disadvantages*	*Advantages*	*Disadvantages*
Does not require changes to the Website or extra hardware installation	Can only record interactions with the Web server	Near real-time reporting	Requires extra code added to the Website
Does not require extra bandwidth	Server must be configured to assign cookies to visitors	Easier to record additional information	Uses extra bandwidth each time the page loads
Freedom to change tools with a relatively small amount of hassle	Only available to companies who run their own Web servers	Able to capture visitor interactions within Flash animations	Can only record successful page loads, not failures
Logs both page request successes and failures	Cannot log physical location		Hard to switch analytic tools

IP addresses and changes to Website content cause messy data. Even though the data may be hard to work with at first, once it is cleaned up, it provides an excellent tool for Web analytics.

CHOOSING KEY PERFORMANCE INDICATORS

In order to get the most out of Web analytics, one must know how to choose effectively which metrics to analyze and combine them in meaningful ways. This means knowing the Website's business goals and then determining which KPIs will provide the most insight.

Knowing Your Business Goals

Every company has specific business goals. Every part of the company works together to achieve them, and the company Website is no exception. In order for a Website to be beneficial, information gathered from its visitors must not merely show what has happened in the past, but it must also be able to improve the site for future visitors. The company must have clearly defined goals for the future and use this information to support strategies that will help it achieve those goals.

For a Website, the first step in achieving this is making sure the data collected from the site is actionable. According to the Web Analytics Association (McFadden, 2005), in order for a company to collect actionable data, it must meet these three criteria: "(1) the business goals must be clear, (2) technology, analytics, and the business must be aligned, and (3) the feedback loop must be complete" (Web Channel Performance Management section, para. 3).

There are many possible methods for meeting these criteria. One is Alignment-Centric Performance Management (Becher, 2005). This approach goes beyond merely reviewing past customer trends to carefully selecting a few key KPIs based on their future business objectives. Even though a wealth of metrics is available from a Website, this does not mean that all metrics are relevant to a company's needs. Reporting large quantities of data is overwhelming, so it is important to look at metrics in context and use them to create KPIs that focus on outcome and not activity. For example, a customer service Website might view the number of emails responded to on the same day they were sent as a measurement of customer satisfaction. A better way to measure customer satisfaction, however, might be to survey the customers on their experience. Although this measurement is subjective, it is a better representation of customer satisfaction because even if a customer receives a response the same day they send out an email, it does not mean that the experience was a good one (Becher, 2005).

Choosing the most beneficial KPIs using this method is achieved by following "The Four M's of Operational Management" as outlined by Becher (2005) which facilitate effective selection of KPIs:

- **Motivate:** Ensure that goals are relevant to everyone involved.
- **Manage:** Encourage collaboration and involvement for achieving these goals.
- **Monitor:** Once selected, track the KPIs and quickly deal with any problems that may arise.
- **Measure:** Identify the root causes of problems and test any assumptions associated with the strategy.

By carefully choosing a few, quality KPIs to monitor and making sure everyone is involved with the strategy, it becomes easier to align a Website's goals with the company's goals because the information is targeted and stakeholders are actively participating.

Another method for ensuring actionable data is Online Business Performance Management (OBPM) (Sapir, 2004). This approach integrates business tools with Web analytics to help companies make better decisions quickly in an ever-changing online environment where customer data is stored in a variety of different departments. The first step in this strategy is gathering all customer data in a central location and condensing it so that the result is all actionable data stored in the same place. Once this information is in place, the next step is choosing relevant KPIs that are aligned with the company's business strategy and then analyzing expected versus actual results (Sapir 2004).

In order to choose the best KPIs and measure the Website's performance against the goals of a business, there must be effective communication between senior executives and online managers. The two groups should work together to define the relevant performance metrics, the overall goals for the Website, and the performance measurements. This method is similar to Alignment-Centric Performance Management in that it aims to aid integration of the Website with the company's business objectives by involving major stakeholders. The ultimate goals of OBPM are increased confidence, organizational accountability, and efficiency (Sapir 2004).

Identifying KPIs Based on Website Type

Unlike metrics, which are numerical representations of data collected from a Website, KPIs are tied to a business strategy and are usually measured by a ratio of two metrics. By choosing KPIs based on the Website type, a business can save both time and money. Although Websites can have more than one function, each site belongs to at least one of the four main categories – commerce, lead generation, content/media, and support/self service (McFadden, 2005). Table 6 shows common KPIs for each Website type:

We discuss each Website type and related KPIs below.

Commerce

The goal of a commerce Website is to get visitors to purchase goods or services directly from the site, with success gauged by the amount of revenue the site brings in. According to Peterson, "commerce analysis tools should provide the 'who, what, when, where, and how' for your online purchasers (2004, p. 92)." In essence, the important information for a commerce Website is who made (or failed to make) a purchase, what was purchased, when purchases were made, where customers are coming from, and how customers are making their purchases. The most valuable KPIs used to answer these questions are conversion rates, average order value, average visit value, customer loyalty, and bounce rate (McFadden,

Table 6. The four types of Websites and examples of associated KPIs (McFadden, 2005)

Website Type	KPIs
Commerce	• Conversion rates • Average order value • Average visit value • Customer loyalty • Bounce rate
Lead Generation	• Conversion rates • Cost per lead • Bounce rate • Traffic concentration
Content/Media	• Visit depth • Returning visitor ratio • New visitor ratio • Page depth
Support/Self service	• Page depth • Bounce rate • Customer satisfaction • Top internal search phrases

2005). Other metrics to consider with a commerce site are which products, categories, and brands are sold on the site and internal site product search that could signal navigation confusion or a new product niche (Peterson, 2004).

A conversion rate is the number of users who perform a specified action divided by the total of a certain type of visitor (i.e. repeat visitors, unique visitors, etc.) over a given period. Types of conversion rates will vary by the needs of the businesses using them, but two common conversion rates for commerce Websites are the order conversion rate (the percent of total visitors who place an order on a Website) and the checkout conversion rate (the percent of total visitors who begin the checkout process). There are also many methods for choosing the group of visitors on which to base your conversion rate. For example, a business may want to filter visitors by excluding visits from robots and Web crawlers (Ansari, Kohavi, Mason, & Zheng, 2001), or they may want to exclude the traffic that "bounces" from the Website or (a slightly trickier measurement) the traffic that is determined not to have intent to purchase anything from the Website (Kaushik, 2006).

It is common for commerce Websites to have conversion rates around 0.5%, but generally good conversion rates will fall in the 2% range depending on how a business structures its conversion rate (FoundPages, 2007). Again, the ultimate goal is to increase total revenue. According to eVision, for each dollar a company spends on improving this KPI, there is \$10 to \$100 return (2007). The methods a business uses to improve their conversion rate (or rates), however, are different depending on which target action that business chooses to measure.

Average order value (AOV) is a ratio of total order revenue to number of orders over a given period. This number is important because it allows the analyzer to derive a cost for each transaction. There are several ways for a business to use this KPI to its advantage. One way is to break down the AOV by advertising campaigns (i.e. email, keyword, banner ad etc.). This way, a business can see which campaigns are bringing in the best customers and spend more effort refining their strategies in those areas (Peterson, 2005). Overall, however, if the cost of making a transaction is greater than the amount of money customers spend for each transaction, the site is not fulfilling its goal.

There are two main ways to correct this. The first is to increase the number of products customers order per transaction, and the second is to increase the overall cost of purchased products. A good technique for achieving this is through product promotions (McFadden, 2005), but many factors influence how and why customers purchase what they do on a Website. These factors are diverse and can range from displaying a certain security image on the site (MarketingSherpa, 2007) to updating the site's internal search (Young, 2007). Like many KPIs, improvement ultimately comes from ongoing research and a small amount of trial and error.

Another KPI, average visit value, measures the total number of visits to the total revenue. This is a measurement of quality traffic important to businesses. It is problematic for a commerce site when, even though it may have many visitors, each visit generates only a small amount of revenue. In that case, even if the total number of visits increased, it would not have a profound impact on overall profits. This KPI is also useful for evaluating the effectiveness of promotional campaigns. If the average visit value decreases after a specific campaign, it is likely that the advertisement is not attracting quality traffic to the site. Another less common factor in this situation could be broken links or a confusing layout in a site's "shopping cart" area. A business can improve the average visit value by using targeted advertising and employing a layout that reduces customer confusion.

Customer loyalty is the ratio of new to existing customers. Many Web analytics tools measure this using visit frequency and transactions, but there are several important factors in this measurement including the time between visits (Mason, 2007). Customer loyalty can even be measured simply with customer satisfaction surveys (SearchCRM, 2007). Loyal customers will not only increase revenue through purchases but also through referrals, potentially limiting advertising costs (QuestionPro).

Bounce rate is a measurement of how many people arrive at a homepage and leave immediately. There are two scenarios that generally qualify as a bounce. In the first scenario, a visitor views only one page on the Website. In the second scenario, a visitor navigates to a Website but only stays on the site for five seconds or less (Avinash, 2007). This could be due to several factors, but in general, visitors who bounce from a Website are not interested in the content. Like average order value, this KPI helps show how much quality traffic a Website receives. A high bounce rate may be a reflection of unintuitive site design or misdirected advertising.

Lead Generation

The goal for a lead generation Website is to obtain user contact information in order to inform them of a company's new products and developments and to gather data for market research; these sites primarily focus on products or services that cannot be purchased directly online. Examples of lead generation include requesting more information by mail or email, applying online, signing up for a newsletter, registering to download product information, and gathering referrals for a partner site (Burby, 2004). The most important KPIs for lead generation sites are conversion rates, cost per lead, bounce rate, and traffic concentration (McFadden, 2005).

Similar to commerce Website KPIs, a conversion rate is the ratio of total visitors to the amount of visitors who perform a specific action. In the case of lead generation Websites, the most common conversion rate is the ratio of total visitors to leads generated. The same visitor filtering techniques mentioned in the previous section can be applied to this measurement (i.e. filtering out robots and Web crawlers and excluding traffic that bounces from the site). This KPI is an essential tool in analyzing marketing strategies. Average lead generation sites have conversion rates ranging from 5-6% and 17-19% conversion rates for exceptionally good sites (Greenfield, 2006). If the conversion rate of a site increases after the implementation of a new marketing strategy, it indicates that the campaign was successful. If it decreases, it indicates that the campaign was not effective and might need to be reworked.

Cost per lead (CPL) refers to the ratio of total expenses to total number of leads, or how much it costs a company to generate a lead; a more targeted measurement of this KPI would be the ratio of total marketing expenses to total number of leads. Like the conversion rate, CPL helps a business gain insight into the effectiveness of its marketing campaigns. A good way to measure the success of this KPI is to make sure that the CPL for a specific marketing campaign is less than the overall CPL (WebSideStory, 2004). Ideally, the CPL should be low, and well-targeted advertising is usually the best way to achieve this.

Lead generation bounce rate is the same measurement as the bounce rate for commerce sites. This KPI is a measurement of visitor retention based off total number of bounces to total number of visitors; a bounce is a visit characterized by a visitor entering the site and immediately leaving. Lead generation sites differ from commerce sites in that they may not require the same level of user interaction. For example, a lead generation site could have a single page where users enter their contact information. Even though they only view one page, the visit is still successful if the Website is able to collect the user's information. In these situations, it is best to base the bounce rate solely off of time spent on the site. As with commerce sites, the best way to decrease a site's bounce rate is to increase advertising effectiveness and decrease visitor confusion.

The final KPI is traffic concentration, or the ratio of the number of visitors to a certain area in a Website to total visitors. This KPI shows which areas of a site have the most visitor interest. For this type of Website, it is ideal to have a high traffic concentration on the page or pages where users enter their contact information.

Content/Media

Content/media Websites focus mainly on advertising, and the main goal of these sites is to increase revenue by keeping visitors on the Website longer and also to keep visitors coming back to the site. In order for these types of sites to succeed, site content must be engaging and frequently updated. If content is only part of a company's Website, the content used in conjunction with other types of pages can be used to draw in visitors and provide a way to immerse them with the site. The main KPIs are visit depth, returning visitors, new visitor percentage, and page depth (McFadden, 2005).

Visit depth (also referred to as depth of visit or path length) is the measurement of the ratio between page views and unique visitors, or how many pages a visitor accesses each visit. As a general rule, visitors with a higher visit depth are interacting more with the Website. If visitors are only viewing a few pages per visit, it means that they are not engaged, and the effectiveness of the site is low. A way to increase a low average visit depth is by creating more targeted content that would be more interesting to the Website's target audience. Another strategy could be increasing the site's interactivity to encourage the users to become more involved with the site and keep them coming back.

Unlike the metric of simply counting the number of returning visitors on a site, the returning visitor KPI is the ratio of unique visitors to total visits. A factor in customer loyalty, this KPI measures the effectiveness of a Website to bring visitors back. A lower ratio for this KPI is best because a lower number means more repeat visitors and more visitors who are interested in and trust the content of the Website. If this KPI is too low, however, it might signal problems in other areas such as a high bounce rate or even click fraud. Click fraud occurs when a person or script is used to generate visits to a Website without having genuine interest in the site. According to a study by Blizzard Internet Marketing, the average for returning visitors to a Website is 23.7% (White, 2006). As with many of the other KPIs for content/media Websites, the best way to improve the returning visitor rate is by having quality content and encouraging interaction with the Website.

New visitor ratio is the measurement of new visitors to unique visitors and is used to determine if a site is attracting new people. When measuring this KPI, the age of the Website plays a role – newer sites will want to attract new people. Similarly, another factor to consider is if the Website is concerned more about customer retention or gaining new customers. As a rule, however, the new visitor ratio should decrease over time as the returning visitor ratio increases. New visitors can be brought to the Website in a variety of different ways, so a good way to increase this KPI is to try different marketing strategies and figure out which campaigns bring the most (and the best) traffic to the site.

The final KPI for content/media sites is page depth. This is the ratio of page views for a specific page and the number of unique visitors to that page. This KPI is similar to visit depth, but its measurements focus more on page popularity. Average page depth can be used to measure interest in specific areas of a Website over time and to make sure that the interests of the visitors match the goals of the Website. If one particular page on a Website has a high page depth, it is an indication that that page is of particular interest to visitors. An example of a page in a Website expected to have a higher page depth would be a news page. Information on a news page is constantly updated so that, while the page is still always in the same location, the content of that page is constantly changing. If a Website has high page depth in a relatively unimportant part of the site, it may signal visitor confusion with navigation in the site or an incorrectly targeted advertising campaign.

Support/Self Service

Websites offering support or self-service are interested in helping users find specialized answers for specific problems. The goals for this type of Website are increasing customer satisfaction and decreasing call center costs; it is more cost-effective for a company to have visitors find information through its Website than it is to operate a call center. The KPIs of interest are visit length, content depth, and bounce rate. In addition, other areas to examine are customer satisfaction metrics and top internal search phrases (McFadden, 2005).

Page depth for support/self service sites is the same measurement as page depth content/media sites – the ratio of page views to unique visitors. With support/self service sites, however, high page depth is not always a good sign. For example, a visitor viewing the same page multiple times may show that the visitor is having trouble finding helpful information on the Website or even that the information the visitor is looking for does not exist on the site. The goal of these types of sites is to help customers find what they need as quickly as possible and with the least amount of navigation through the site (CCMedia, 2007). The best way to keep page depth low is to keep visitor confusion low.

As with the bounce rate of other Website types, the bounce rate for support/self service sites reflects ease of use, advertising effectiveness, and visitor interest. A low bounce rate means that quality traffic is coming to the Website and deciding that the site's information is potentially useful. Poor advertisement campaigns and poor Website layout will increase a site's bounce rate.

Customer satisfaction deals with how the users rate their experience on a site and is usually collected directly from the visitors (not from log files), either through online surveys or through satisfaction ratings. Although it is not a KPI in the traditional sense, gathering data directly from visitors to a Website is a valuable tool for figuring out exactly what visitors want. Customer satisfaction measurements can deal with customer ratings, concern reports, corrective actions, response time, and product delivery. Using these numbers, one can compare the online experience of the Website's customers to the industry average and make improvements according to visitors' expressed needs.

Similarly, top internal search phrases applies only to sites with internal search, but it can be used to measure what information customers are most interested in which can lead to improvement in site navigation. This information can be used to direct support resources to the areas generating the most user interest, as well as identify which parts of the Website users may have trouble accessing. In addition, if many visitors are searching for a product not supported on the Website, it could be a sign of ineffective marketing.

Regardless of Website type, the KPIs listed above are not the only KPIs that can prove useful in analyzing a site's traffic, but they provide a good starting point. The main thing to remember is that no matter what KPIs a company chooses, they must be aligned with its business goals, and more KPIs do not necessarily mean better analysis – quality is more important than quantity.

KEY BEST PRACTICES

In this chapter, we have addressed which metrics can be gathered from a Website, how to gather them, and how to determine which information is important. But how can this help improve a business? To answer this, the Web Analytics Association provides nine key best practices to follow when analyzing a Website (McFadden, 2005). Figure 1 outlines this process.

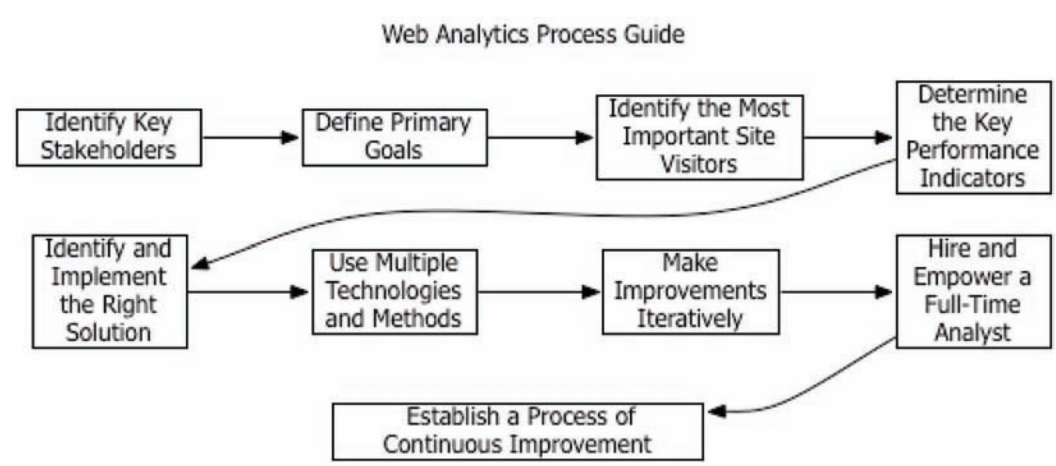
Identify Key Stakeholders

A stakeholder is anyone who holds an interest in a Website. This includes management, site developers, visitors, and anyone else who creates, maintains, uses, or is affected by the site. In order for the Website to be truly beneficial, it must integrate input from all major stakeholders. Involving people from different parts of the company also makes it more likely that they will embrace the Website as a valuable tool.

Define Primary Goals for Your Website

To know the primary goals of a Website, one must first understand the primary goals of its key

Figure 1. The best key practices of Web analytics



stakeholders. This could include such goals as increasing revenue, cutting expenses, and increasing customer loyalty (McFadden, 2005). Once those goals have been defined, discuss each goal and prioritize them in terms of how the Website can most benefit the company. As always, beware of political conflict between stakeholders and their individual goals as well as assumptions they may have made while determining their goals that may not necessarily be true. By going through this process, a company can make sure that goals do not conflict and that stakeholders are kept happy.

Identify the Most Important Site Visitors

According to Sterne, corporate executives categorize their visitors differently in terms of importance. Most companies classify their most important visitors as ones who either visit the site regularly, stay the longest on the site, view the most pages, purchase the most goods or services, purchase goods most frequently, or spend the most money (Sterne, n. d.). There are three types of customers – (1) customers a company wants to keep who have a high current value and high future potential, (2) customers a company wants to grow who can either have a high current value and low future potential or low current value and high future potential, and (3) customers a company wants to eliminate who have a low current value and low future potential. The most important visitor to a Website, however, is the one who ultimately brings in the most revenue. Defining the different levels of customers will allow one to consider the goals of these visitors. What improvements can be made to the Website in order to improve their browsing experiences?

Determine the Key Performance Indicators

The next step is picking the metrics that will be most beneficial in improving the site and eliminating the ones that will provide little or no insight into its goals. One can then use these metrics to determine which KPI you wish to monitor. As mentioned in the previous section, the Website type – commerce, lead generation, media/content, or support/self service – plays a key role in which KPIs are most effective for analyzing site traffic.

Identify and Implement the Right Solution

This step deals with finding the right Web analytics technology to meet the business's specific needs. After the KPIs have been defined, this step should be easy. The most important things to consider are the budget, software flexibility and ease of use, and how well the technology will work with the needed metrics. McFadden suggests that it is also a good idea to run a pilot test of the top two vendor choices (McFadden, 2005). We will expand on this topic further in the next section.

Use Multiple Technologies and Methods

Web analytics is not the only method available for improving a Website. To achieve a more holistic view of a site's visitors, one can also use tools such as focus groups, online surveys, usability studies, and customer services contact analysis (McFadden, 2005).

Make Improvements Iteratively

When analyzing a Website's data, it is helpful to add gradual improvements to the Website instead of updating too many facets of the Website at once. By doing this one can monitor if a singular change is an improvement or if it is actually hurting the site.

Hire and Empower a Full-Time Analyst

It is important to put a person in charge of the data once it is collected. According to the Web Analytics Association, a good analyst understands business needs (which means communicating well with the stakeholders), has knowledge of technology and marketing, has respect, credibility, and authority, and is already a company employee. Although it may seem like hiring a full-time analyst is expensive, many experts agree that the return on revenue should be more than enough compensation to recoup the cost (McFadden, 2005).

Establish a Process of Continuous Improvement

Once the Web analysis process is decided upon, continuous evaluation is paramount. This means reviewing the goals and metrics and monitoring new changes and features which are added to the Website. It is important that the improvements are adding value to the site and meeting expectations.

SPECIFIC TOOLS

Choosing a Tool

Once the company decides what it wants out of the Web analysis, it is time to find the right tool. Kaushik outlines ten important questions to ask Web analytics vendors (2007):

1. *What is the difference between your tool and free Web analytics tools?* Since the company who owns the Website will be paying money for a service, it is important to know why that service is better than free services (for example, Google Analytics). Look for an answer that outlines the features and functionality of the vendor. Do not look for answers about increased costs because of privacy threats or poor support offered by free analytics tools.
2. *Do you offer a software version of your tool?* Generally, a business will want to look for a tool that is software based and can run on their own servers. If a tool does not have a software version but plans to make one in the future, it shows insight into how prepared they are to offer future products if there is interest.
3. *What methods do you use to capture data?* If you remember from the first section, there are two main ways to capture visitor data from a Website – log files and page tagging. Ideally, one should look for a vendor that offers both, but what they have used in the past is also important. Because technology is constantly changing, look for a company that has kept up with these changes in the past by providing creative solutions.
4. *Can you help me calculate the total cost of ownership for your tool?* The total cost of ownership for a Web analytics tool depends on the specific company, the systems they have in place, and the pricing of the prospective Web analytics tool. In order to make this calculation, one must consider the following:
    a. Cost per page view.
    b. Incremental costs (i.e. charges for overuse or advanced features).
    c. Annual support costs after the first year.
    d. Cost of professional services (i.e. installation, troubleshooting, or customization).
    e. Cost of additional hardware you may need.
    f. Administration costs (which includes the cost of an analyst and any additional employees you may need to hire).
5. *What kind of support do you offer?* Many vendors advertise free support, but it is

important to be aware of any limits that could incur additional costs. It is also important to note how extensive their support is and how willing they are to help.

6. *What features do you provide that will allow me to segment my data?* Segmentation allows companies to manipulate their data. Look for the vendor's ability to segment your data after it is recorded. Many vendors use JavaScript tags on each page to segment the data as it is captured, meaning that the company has to know exactly what it wants from the data before having the data itself; this approach is less flexible.
7. *What options do I have to export data into our system?* It is important to know who ultimately owns and stores the data and whether it is possible to obtain both raw and processed data. Most vendors will not provide companies with the data exactly as they need it, but it is a good idea to realize what kind of data is available before a final decision is made.
8. *Which features do you provide for integrating data from other sources into your tool?* This question deals with the previous section's Key Best Practice #6: Use Multiple Technologies and Methods. If a company has other data it wants to bring to the tool (such as survey data or data from your ad agency), bring them up to the potential analytics vendor and see if it is possible to integrate this information into their tool.
9. *What new features are you developing that would keep you ahead of your competition?* Not only will the answer to this question tell how much the vendor has thought about future functionality, it will also show how much they know about their competitors.
10. *Why did you lose your last two clients? Who are they using now?* The benefits of this question are obvious -- by knowing how they lost prior business, the business can be confident that it has made the right choice.

Some examples of free and commercially available analytics tools are discussed below.

Free Tools

One of the most popular free analytics tools on the Web now is Google Analytics (previously Urchin). Google Analytics (http://www.google.com/analytics/) uses page tagging to collect information from visitors to a site. In addition to expanding on the already highly regarded Urchin analytics tool, it also provides support for integrating other analytic information (for example, WordPress and AdWords). Google Analytics reports many of the KPIs discussed in the previous sections including depth of visit, returning visitors, and page depth.

There is, however, concern about privacy issues regarding Google Analytics because Google uses their default privacy policy for their analytics tools, but the company assures its Google Analytics users that only account owners and people to whom the owners give permission will have access to the data (Dodoo, 2006). Microsoft also provides a free Web analytic software called Gatineau (Thomas, 2007).

Paid Tools

InfoWorld provides an in-depth analysis comparing the top four Web analytic companies – Coremetrics, WebTrends, Omniture, and WebSideStory HBX (Heck, 2005). They created a scoring chart and measured each vendor on reporting, administration, performance, ease-of-use, support, and value. Coremetrics received a score of 8.3 with its highest ratings in administration and support. It is a hosted service that offers special configurations for financial, retail, and travel services. WebTrends also earned a score of 8.3 with its highest rating in reporting. This tool is expensive, but it offers a wide range of performance statistics and both client and server hosting. Omniture is next in line with a score of 8.4 with its highest ratings in reporting and support. It is an ASP reporting application that excels in providing relevant reports. WebSideStory had the highest score of 8.7 with its highest ratings in reporting, administration, ease-of-use, and support. This tool is easy to use and is appropriate for many different types of businesses.

CONCLUSION

The first step in analyzing your Website and Website visitors is understanding and analyzing your business goals and then using that information to carefully choose your metrics. In order to take full advantage of the information gathered from your site's visitors, you must consider alternative methods such as focus groups and online surveys, make site improvements gradually, hire a full-time analyst, and realize that your site's improvement is a process and not a one-time activity. Using these key best practices and choosing the right analytics vendor to fit your business will save your company money and ultimately increase revenue.

As Web analytics continues to mature, the methods vendors use to collect information are becoming more refined. One article speculates that companies will find concrete answers to the problems with cookies and unique visitors (Eisenberg, 2005). The Web analytics industry as a whole is also expanding. According to Eisenberg (2005), a recent Jupiter report predicts an increase in the Web analytics industry – 20 percent annually. More and more businesses are realizing the benefits of critically analyzing their Website traffic and are taking measures to improve their profits based off these numbers. Regardless of business size and objective, an effective Web analytics strategy is becoming increasingly essential for online success.

KEY TERMS

Abandonment Rate: KPI that measures the percentage of visitors who got to that point on the site but decided not to perform the target action.

Alignment-Centric Performance Management: Method of defining a site's business goals by choosing only a few key performance indicators.

Average Order Value: KPI that measures the total revenue to the total number of orders.

Average Time on Site (ATOS): See *visit length*.

Checkout Conversion Rate: KPI that measures the percent of total visitors who begin the checkout process.

Commerce Website: A type of Website where the goal is to get visitors to purchase goods or services directly from the site.

Committed Visitor Index: KPI that measures the percentage of visitors that view more than one page or spend more than 1 minute on a site (these measurements should be adjusted according to site type).

Content/Media Website: A type of Website focused on advertising.

Conversion Rate: KPI that measures the percentage of total visitors to a Website that perform a specific action.

Cost Per Lead (CPL): KPI that measures the ratio of marketing expenses to total leads and shows how much it costs a company to generate a lead.

Customer Satisfaction Metrics: KPI that measures how the users rate their experience on a site.

Customer Loyalty: KPI that measures the ratio of new to existing customers.

Demographics and System Statistics: A metric that measures the physical location and information of the system used to access the Website.

Depth of Visit: KPI that measures the ratio between page views and visitors.

Internal Search: A metric that measures information on keywords and results pages viewed using a search engine embedded in the Website.

Key Performance Indicator (KPI): A combination of metrics tied to a business strategy.

Lead Generation Website: A type of Website that is used to obtain user contact information in order to inform them of a company's new products and developments, and to gather data for market research.

Log File: Log kept by a Web server of information about requests made to the Website including (but not limited to) visitor IP address, date and time of the request, request page, referrer, and information on the visitor's Web browser and operating system.

Log File Analysis: Method of gathering metrics that uses information gathered from a log file to gather Website statistics.

Metrics: Statistical data collected from a Website such as number of unique visitors, most popular pages, etc.

New Visitor: A user who is accessing a Website for the first time.

New Visitor Percentage: KPI that measures the ratio of new visitors to unique visitors.

Online Business Performance Management (OBPM): Method of defining a site's business goals that emphasizes the integration of business tools and Web analytics to make better decisions quickly in an ever-changing online environment.

Order Conversion Rate: KPI that measures the percent of total visitors who place an order on a Website.

Page Depth: KPI that measures the ratio of page views for a specific page and the number of unique visitors to that page.

Page Tagging: Method of gathering metrics that uses an invisible image to detect when a page has been successfully loaded and then uses JavaScript to send information about the page and the visitor back to a remote server.

Prospect Rate: KPI that measures the percentage of visitors who get to the point in a site where they can perform the target action (even if they do not actually complete it).

Referrers and Keyword Analysis: A metric that measures which sites have directed traffic to the Website and which keywords visitors are using to find the Website.

Repeat Visitor: A user who has been to a Website before and is now returning.

Returning Visitor: KPI that measures the ratio of unique visitors to total visits.

Search Engine Referrals: KPI that measures the ratio of referrals to a site from specific search engines compared to the industry average.

Single Access Ratio: KPI that measures the ratio of total single access pages (or pages where the visitor enters the site and exits immediately from the same page) to total entry pages.

Stickiness: KPI that measures how many people arrive at a homepage and proceed to traverse the rest of the site.

Support/Self Service Website: A type of Website that focuses on helping users find specialized answers for their particular problems.

Top Pages: A metric that measures the pages in a Website that receive the most traffic.

Total Bounce Rate: KPI that measures the percentage of visitors who scan the site and then leave.

Traffic Concentration: KPI that measures the ratio of number of visitors to a certain area in a Website to total visitors.

Unique Visit: One visit to a Website (regardless of if the user has previously visited the site); an alternative to unique visitors.

Unique Visitor: A specific user who accesses a Website.

Visit Length: A metric that measures total amount of time a visitor spends on the Website.

Visit Value: KPI that measures the total number of visits to total revenue.

Visitor Path: A metric that measures the route a visitor uses to navigate through the Website.

Visitor Type: A metric that measures users who access a Website. Each user who visits the Website is a unique user. If it is a user's first time to the Website, that visitor is a new visitor, and if it is not the user's first time, that visitor is a repeat visitor.

Web Analytics: The measurement of visitor behavior on a Website.

Chapter 1.10
Basics to Develop Web Services for Human Resources

Roman Povalej
University of Karlsruhe (TH), Germany

Peter Weiß
University of Karlsruhe (TH), Germany

INTRODUCTION

In this article certain pillars as basics are presented being necessary to develop Web services (W3C, 2007) supporting human resource (HR) processes like assessing, hiring, modeling information systems, staffing, and so forth; by the help of these Web services. Current HR information systems in general do not adequately support tasks related to cross-organizational or global skills and competence management. In the following, the topic is presented which relates to knowledge management especially to "communities of practice," as well as related topics such as e-skills and ICT (information and communication technologies) professionalism; the latter currently being broadly discussed by experts in Europe.

DOI: 10.4018/978-1-59904-883-3.ch013

HR managers of a company or an organization are challenged through the need to formalize skills requirements and to continuously monitor the skills demand inside the company. Obtaining ICT skills are not a one-time event. Technological change advances at a high speed and requires that skills need continually to be kept up-to-date and relevant (The European e-Skills Forum [ESF], 2005).

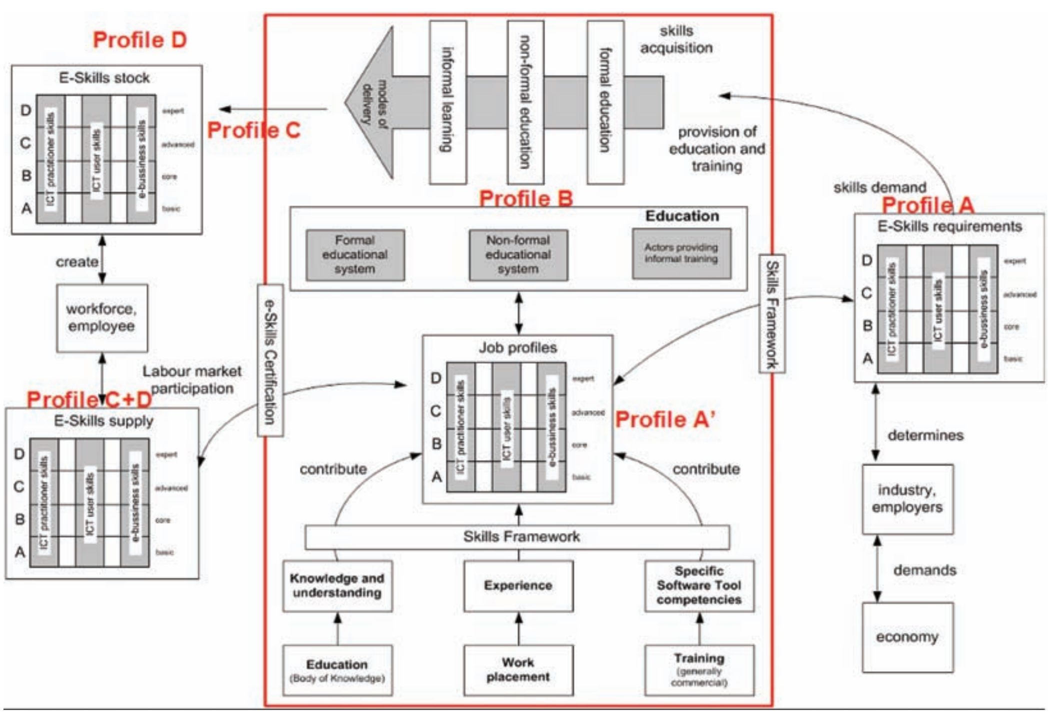
During the last years, new concepts have emerged which intend to empower learners and individuals to steer learning processes to a large extent on their own. Learning objectives tend to be increasingly individual in character (ESF, 2005).

In this context, providing an appropriate infrastructure which supports the continuing professional development (CPD) of employees is today a key issue. CPD processes require a respective infrastructure encompasses besides qualifications, skills/competence frameworks and body of knowledge, as well required standards for competence, skills, and appropriate career and development services. Standards encompass educational and industry-oriented performance standards which in turn are expressed preferably through a common language as competence and skills standards. The governance and administration of the CPD process require the availability of flexible and personalized certification services which offer the formal validation of individuals' learning achievements independent of where and how they were acquired.

Recruitment and internal mobility are typical use cases to identify the right people wanted, by matching their assessment outcomes with job positions requested. In case a company needs new ICT competence, the HR manager in charge has to draw up a job advertisement, which describes the required knowledge, skills, competences (KSC), and qualifications for the specific job role. The information is generally structured in a job profile, which mirrors ideally the companies core competences; but how can this be efficiently done or supported by a concept method and/or tool, how can be potential employees be addressed independently of their national origin? Further scenarios can be derived from Figure 1.

Noticeably, information about requirements is exchanged amongst various players along the value chain. Hence, looking at ICT skills requirements necessitates looking at the belonging processes as a whole. This relates to a common language which allows exchanging information amongst the various players involved and exchange of data stored in respective HR-systems. The latter, in particular, motivates data services which facilitate sharing of data required for the execution of tasks along the HR processes (such as recruitment of ICT professionals). Typically, systems do not have the required interoperability because the applied data models differ in structure and semantics. In the following, we look at how to achieve better interoperability of systems and

Figure 1. Supply and demand of e-skills



an enhanced sharing of information about ICT skills requirements typically stored in job or ICT worker profiles.

Competence-based professional profiles are a referred concept to define and exchange information about respective professional standards. The profile is the description of competence required to operate on a process, on a service, or for a definite role, inside a direction or a function, a working team, or a project. It shows as much explicit as possible which type of know-how needs an organization has in terms of competence. In a most diffused configuration, the competence based profile is defined with reference to an organizational position or role. The competence based profile of a role has to be built up without any reference to single persons that occupied this role or are candidates to cover the role in the future.

In the following, the article looks at a common language and ICT worker profiles as a constituent part and central element of an adequate management of HR processes in general and CPD processes specifically. The article presents a conceptual model which allows expanding existing barriers of HR systems. Web services are seen as an appropriate concept to implement required functionality and processes.

BACKGROUND

The competitiveness of European industry depends on both the effective use of ICT for industrial and business processes and the KSC and qualifications of existing and new employees (ESF, 2005).

Today, nearly every area of economic activity is affected by ICT and the pace of technological change and short technology life cycles makes these the most dynamic of occupations (Cedefop, 2005); scilicet companies as well as ICT employees (and also others) have an ongoing need to keep their KSC and qualifications up-to-date to prevail against competitors. In respect thereof, ICT certifications are useful to validate ICT employees' market value and often they rank a key role in the hiring process.

In the first place, ICT companies, but actually all companies, employ people with ICT skills as well as people with a range of other relevant skills. Often the number of ICT practitioners in such ICT user organizations (e.g., banks, manufacturing companies, and airlines) is greater than the number employed in ICT companies.

New competency-based systems of certification of individual employees and/or others were, are, and further on, will be established within the information technology field and offered on the market; this is mainly driven by ICT vendors, the expected profit is highly valued.

Competence encompasses "[…] the demonstration of relevant, up-to-date skills and capabilities appropriate to a particular task or role with practical experience to complement theoretical knowledge" (Hughes & Thompson, 2007). This includes as well, necessary soft skills such as interpersonal and communication skills as well as an understanding of the business domain. We argue that performance components are an adequate means to develop necessary skills and to avoid that qualification measures coincide. Figure 1 shows the supply and demand of e-skills.

E-skills present a mainly political driven joint initiative of stakeholders in Europe such as the European Commission, ICT professionals associations, and international ICT vendor industry associations. Subsequently, we argue why e-skills require joint activities and concerted actions.

Each stakeholder determines their own needed and relevant e-skills requirements (profile A). Education institutions determine their curricula (profile B) which consist of e-skills which should be taught to the students. Industry and employers determine their e-skills requirements (profile A) to manage their tasks and challenges in the economy. Sometimes the requirements of these two groups do not exactly match, for example, parts of the curricula are in general concepts, methods, and tools about databases; however, the industry demands product-related knowledge about a specific database, often they do not notice that the parts of the curricula will be actual on the long run, whereas product-related knowledge about one specific database could be shortly unusable, because the belonging software product is no longer offered and used. After education, every person becomes part of the e-skills stock (profile C) with their own portfolio (profile D), and with their participation at the labor market they build the e-skills supply (profile C+D). The relevant job profiles are managed within companies' skills framework (profile A') and are influenced by the e-skills requirements (profile A), e-skills stocks (profile C and profile D), and e-skills supply (profile C+D). It is a big challenge to compare and/or to match these (job) profiles (profile A, B, C, D, C+D, A') among themselves because of lack of a common language. The degree of difficulty is much higher on the European level.

Web service adoption in the industry has allowed organizations to share information with their partners, providers, and customers in a standardized manner. Web services provide a successful way to communicate distributed applications in a platform-independent and loosely coupled manner. The integration of applications is one of the main challenges when building ICT solutions. Integration is often achieved using costly customized solutions for every pair of applications. Web service technologies are a set of standards that allow software interfaces to be defined using XML (extensible markup language) as the message format and the Internet infrastructure for message transport. While lowering costs, Web service technologies by themselves do not ensure that two businesses use the same data structures or business protocols; neither do they provide the means to resolve potential conflicts (Lausen, Brujin, Keller, & Lara, 2006). In order to deal with existing interoperability issues, ontology-based models for describing Web services are proposed. Hence, Web services are in the wider context of analysis, we will look at issues of common semantics to enable communication of and automated data exchange between various applications in HR systems.

We see that electronic data interchange and integration has potential to make internal HR management processes more flexible and faster, as well as more efficient and effective.

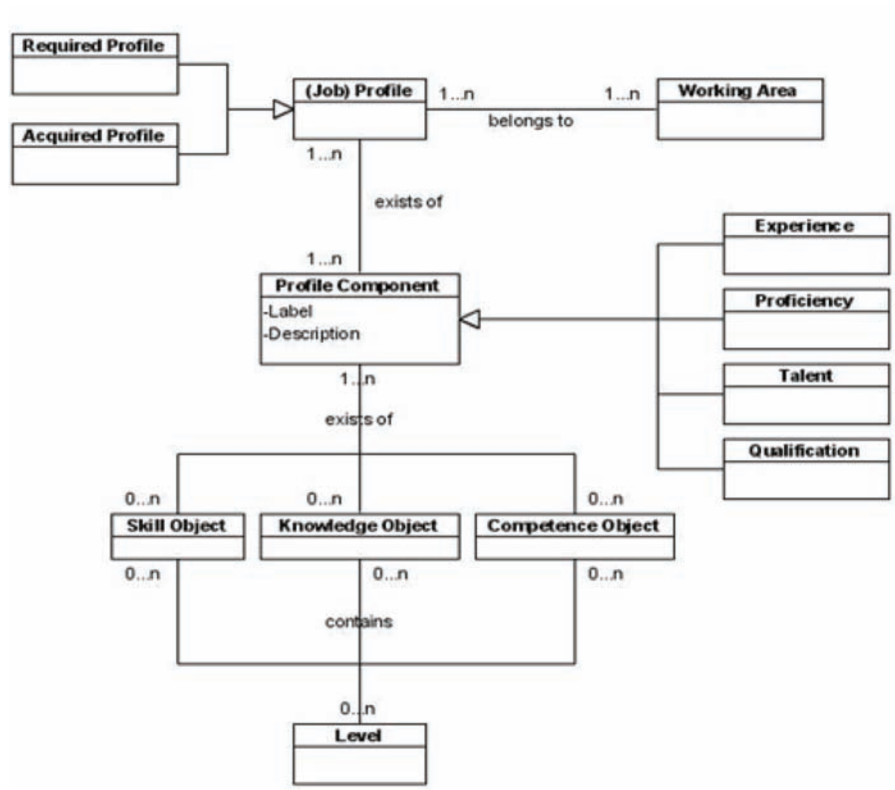
CONCEPTUAL DATA MODEL

During schooling and education, for (the first) letter of application, for a successful professional advancement, and more: the whole working life belongs to the crucial points KSC and qualifications. There are standardized data models describing competences in a re-usable way: IEEE Reusable Competency Definition (RCD, 2007) and HR-XML (2004) (further information in Povalej and Weiß, 2007). When certain competences are once defined they can be re-used again and again, for example, in different job advertisements or describing several job profiles. Further on, employees can use the already defined competences to describe their own ones.

Here are some clues based on the results of the analyses of these two standardized data models which could be extracted for our conceptual data model (Povalej & Weiß, 2007): the re-usability and the flexibility are strengthened through an object oriented approach; one competency consists of the components skills, context, and proficiency level; context and proficiency level has to be clearly definable which is a precondition for profile matching and domain-wide re-usability; free description area out of RCD is needed and it represents the smallest skills unit; additional, the component grade is introduced. Figure 2 displays the connections and dependencies between relevant objects or classes of a job profile model.

A job profile describes among others, KSC and qualifications which employees have or should have to cope with work tasks successfully within their working areas. Hence, there are two kinds

Figure 2. Example of a job profile model



of profiles: (1) the required profile contains all information about KSC and qualification which employees should have to manage their tasks in a company and (2) the acquired profile contains all information about KSC and qualification which employees gained in their life. Every (job) profile belongs to at least one working area. Further, on the (job) profile exists of one or more profile components—each profile component represents experience, proficiency, talent, or qualification. Every profile component exists of none, one, or many KSC objects, whereby every component contains none or one level.

The code in Figure 3 is an extract from a HR-XML schema describing competence and level belonging to a job profile.

Figure 4 displays exemplarily the component profile of our conceptual model (Povalej & Weiß, 2007).

CONCEPTUAL META-FRAMEWORK

However, in order to achieve transparency and comparability of ICT worker profiles, data structures need to be analyzed and their semantics or meta data needs to be described. Subsequently, we look at the modeling of profile structure and semantics. Meta data is preferably described and stored in the form of ontologies. Preparatory work to create ontologies requires analyzing the underlying data structure in a formal way, which then determines our structure of data sets stored in profiles. We present the results of our analysis of meta data applied in major ICT skills/competence frameworks.

The smallest building block or unit of qualifications has to be defined (CEN/ISSS, 2005; Weiß, Povalej, & Stucky, 2005; Weiß, Stucky, Dolan, & Bumann, 2005).

Figure 3. Exemplary extract from a HR-XML schema

```

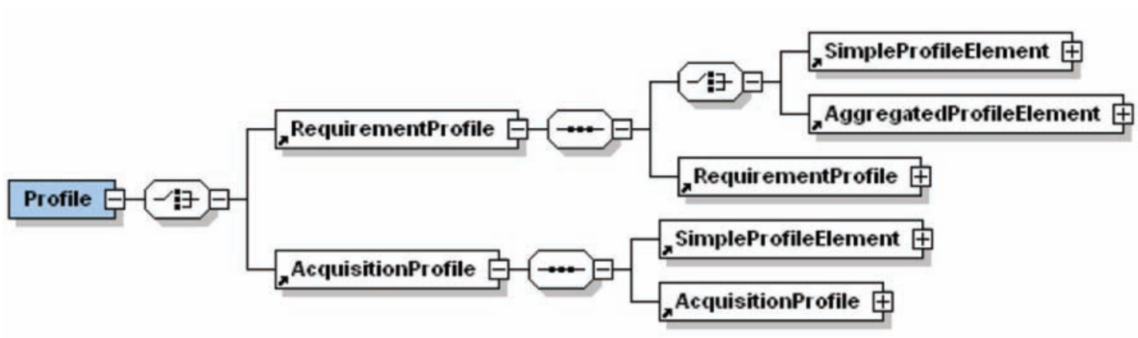
                <xsd:enumeration value="compLevelTarget"/>
                <xsd:enumeration value="compLevelActual"/>
[...]
<xsd:complexType name="CompetenceType">
        <xsd:sequence>
                <xsd:element name="CompId">
                        <xsd:complexType>
        <xsd:attribute name="id" type="xsd:string" use="required"/>
[...]
```

Figure 4. Exemplary component profile (Source: Povalej & Weiß, 2007)



In the following section, the developed matrix of profiles P is described (further information: Weiß, Povalej, & Stucky, 2005; Povalej & Weiß, 2007). In our approach, a profile constitutes on three sub-systems to be defined and specified by a respective modeler/developer: 1) the general description of qualification component (QC) (e.g., constructs described as learning outcome (LOC) by KSC), 2) the specific description of the working area (WA), job role, function, business process, and so forth, and 3) the performance level required. These three elements combined, define the qualification unit (QU) as the smallest describable and measurable unit within a qualification or profile P. These results are summarized in the definition of ICT worker sector profile P. An ICT worker profile is defined as the selection of the tupel (WA, QC, L) and can be described as matrix P with the job role q as follows (notation: Figure 5) (our approach corresponds to the central concepts or terms suggested by Cedefop, 2003):

$$P_q = L_q = \left(l_{qij}\right)_{j=1...n}^{i=1...m} = \left(wa_i, qc_j\right)_{j=1...n}^{i=1...m} \qquad (1)$$

FUTURE TRENDS

CEN/ISSS (2007) is working on a European e-competence framework. A team of experts has been appointed and will produce guidelines for the developments of a European e-competence framework for consensus building. The team involves experts from stakeholders of leading frameworks such as SFIA in UK, AITTS in

Figure 5. Overview of applied notation (Source: Weiß, Povalej, & Stucky, 2005)

Element/ concept	Notation
P	set of profiles; $P = \{q_1, \ldots q_m\}$
L	set of levels (vertical)
QC	qualification component as general description of the smallest unit of a qualification to be described; QC may be expressed as set of LOC on basis of KSC in relation to the intended application context (QC = LOC) (e.g. general European Qualification Framework descriptions)
WA	set of working areas (horizontal level e.g. 'sales and marketing', 'management and administration'; this is applied synonymously with the terms 'field of work', 'function', 'business process' etc.); $WA = \{wa_1, \ldots wa_m\}$; if higher granularity is required, WA may be subdivided in further sub-categories
q	job role e.g. software developer, information system analyst, etc.
i, j	indices to define KSC category based on typology (WA, QC)
m, n	indices for existing numbers of categories for WA, QC

Germany, CIGREF in France, and ECCO in Italy. The European e-competence framework is addressed to HR managers, ICT managers, and ICT practitioners/ professionals as well as training institutions and educational bodies. The framework intends to contribute to the daily work of HR managers as an international planning and development tool.

The results will be a basic structure for the development of vocabularies and skills/competence dictionaries. Building vocabularies and dictionaries requires in depth domain knowledge of ICT competences in industry. Hence, the European e-competence framework delivers the content which populates profiles and instantiates described meta data structure.

KSC described in coherence with the framework structure allows exchanging and reusing this information in various HR and CPD processes. The framework builds a grid which is spanned mainly by the dimensions competence areas and respective descriptors to specify attitudes, skills, and knowledge. Furthermore, levels and the orientation towards ICT processes are considered. The next steps require to populate the grid and to build dictionaries and catalogues of competence descriptions. The reuse of data and the exchange of information between various systems can be seen as particular challenges.

Portfolios as well as e-portfolios are closely linked to (job) profiles. Hence, consistently, there should be a more detailed review about the connection between these areas. Butler (2006) made the following recommendation for the success of e-portfolios: "Institutions need to be aware of the impact that an electronic portfolio development will have. Electronic portfolios need to be an integral part of a programme of study, not an 'added-on' assessment, which may necessitate the review and restructuring of courses. The type of portfolio required, its purpose and its audience need to be clearly articulated."

CONCLUSION

A detailed consideration of the supply and demand of e-skills (or further knowledge, skills, competences, and qualifications) on the labor market is crucial for the development of a common European framework. It has been pointed out that a common language and a shared common framework are needed.

Further, this article accentuated the formal description of the smallest unit as a building block of qualifications and for analyzing ICT worker profiles. Qualification units are the smallest element to be scrutinized in respective competence assessments and in the certification process. By the help of our developed and presented conceptual data model (derived from standardized data models) as well as our conceptual framework (derived from existing frameworks using the meta-level), ICT competence profiles, or in general, profiles can be modeled at the meta-, reference, and application level (Weiß, Povalej, & Stucky, 2005).

Hence, there are now the necessary basics to develop further Web services for human resources. Central aims are to create the "right" conditions to attract talented people by respective career guidance, information services, and by highlighting flexible entry points to the ICT profession—these all offered as Web services.

The next steps are to develop further the meta-framework for KSC and qualifications. Further on, our up to now work is also the basic for further development of KSC and qualification catalogues and repositories. At the same time the conceptual models will be implemented to real world systems, considering these catalogues and repositories, and also in the future, Web services for a higher transparency, comparability, transferability, and interchangeability.

KEY TERMS

Certification: One process that formally validates the knowledge, skills, and competences (and/or know-how, know-what, know-why) acquired by an individual, following a standard assessment procedure.

Data Modeling: The process of analyzing and identifying data objects and their relationships amongst each other within certain contexts like business or others where they are used. It is a first step into object-oriented programming,

E-Portfolio: A Web-based information management system that uses electronic media and services. In the first line, it is used for self-expression, for example, trying to establish contacts for private or professional matters.

Framework: Set of assumptions, concepts, conditions, methods, preconditions, values, practices, and so forth, that constitutes a way of viewing reality respectively, that supports through making available blueprints within certain contexts, like ICT development or building projects.

Human Resources: A modern conceptuality in the economy, it describes persons as manpower and/or resources. Through this, the importance of employees should be emphasized.

Information and Communication Technologies (ICT): Technologies which provides for the electronic input, storage, retrieval, processing, transmission, and dissemination of information. Often, ICT are linked with a particular context, for example, ICT in education, health care, or libraries.

Job Profiles: Written definitions of primary job duties, key responsibilities, necessary KSC, and qualification, education, experiences, proficiencies, talent, personal characteristics sought in a candidate, and so forth. They belong to certain working areas and are subdivided into components which exist of objects like KSC, including the belonging level. There are required and acquired ones.

Meta Modeling: The analysis, building up, and development of constraints, concepts, frames, methods models, rules, theories, and so forth, practicable and useful for modeling within certain domains to cope with predefined challenges. In general, a model is an abstraction of objects in the real world; a meta-model is an abstraction of model itself.

Qualification: Official record (certificate, diploma) of achievement which recognizes successful completion of education or training, or satisfactory performance in a test or examination.

Web Services: Enterprise applications that exchange data, share tasks, and automate processes over the Internet.

Chapter 1.11
Web 2.0 and E-Discovery

Bryan Kimes
Altria Client Services, Inc., USA

ABSTRACT

Companies today face an overwhelming amount of digital information, and many of them are involved at some point in civil litigation. When a company is in the discovery (pretrial) phase of civil litigation, it usually exchanges information, including documents, with the opposing party in the litigation. The Federal Rules of Civil Procedure, which govern civil litigation in federal courts, were amended in 2006 to provide additional guidance to parties with regard to electronically stored information. The management teams of many U.S. corporations are working with their IT departments and lawyers in order to understand the sources of electronically stored information that may be potentially relevant to their litigation. Over the last 20 years, technology has grown increasingly more complex, from the early mainframe and personal computers to sophisticated e-mail and instant messaging applications that enable users to send and receive millions of messages every day. This chapter addresses the issues companies may face related to the discovery of electronically stored information as a result of new communication technologies, including Web 2.0 applications.

INTRODUCTION

Companies today are dealing with new technologies and a growing amount of digital information. Each year, the global information growth is larger than any previous year, and that trend is not showing any signs of slowing down. In 2002, an estimated 5 exabytes of digital information were created worldwide. For reference, 5 exabytes is the equivalent of 37,000 libraries the size of the Library of Congress (University of California at Berkley, 2003). The annual growth is roughly doubling each year, and U.S. corporations are contributing to this trend. Electronic communication technologies, including e-mail as well as next-generation Web 2.0 social technologies (e.g., instant messaging [IM], blogs, and wikis), are also contributing to this rapid growth. For example, Cellular-News reported that Gartner predicts that an estimated 1.9 trillion instant messages were sent worldwide in 2007 ("SMSs to Surpass 2 Trillion

DOI: 10.4018/978-1-60566-122-3.ch006

Messages in Major Markets in 2008," 2007). These new technologies are transforming modern organizations and their employees. Corporate technology managers are assessing the potential benefits of these new technologies relative to the burden and risk they present to the organization, including that from litigation.

This chapter is not intended to be a comprehensive review of the phases of civil litigation or the Federal Rules of Civil Procedure (FRCP). In addition, the author of this chapter is not a lawyer and the information in this chapter is generalized and not intended for specific situations, and should not be substituted for the advice of a lawyer. The following is an overview of the business issues related to managing electronically stored information that may be required in litigation. By way of background, many companies will face civil litigation, which is when one individual or organization sues another seeking relief, oftentimes for money damages.

E-DISCOVERY BACKGROUND

The *United States v. Microsoft* case, which was tried in 1998, is a famous civil case in which the United States Department of Justice (DOJ) filed an antitrust claim against the software giant alleging it used its monopoly power of the Windows operating system to bundle its Internet Explorer Web browser. The government claimed that other Web browsers, such as Netscape, were not able to compete in the Web browser market due to Microsoft's positioning of Internet Explorer within the Windows operating system. The DOJ won in the trial court, but an appeals court overturned the decision and the case later settled. The Microsoft case was full of headlines and was an example of a case where e-mail played a critical role. The DOJ trial lawyers used internal Microsoft e-mails, many authored by senior executives, including Bill Gates, to demonstrate the company's alleged strategy to "cut off Netscape's air supply" (United States Department of Justice, 1999).

Civil litigation follows specific procedures. Cases in United States federal courts follow the Federal Rules of Civil Procedure. The Federal Rules define the rules into different categories, including Commencement of Action, Pleadings and Motions, Parties, Deposition and Discovery, Trial, and Judgment. The remainder of this chapter will focus on the discovery phase of civil litigation. During the discovery phase of a case, thousands or even millions of documents may be collected, reviewed, and produced from the files of either party in the lawsuit.

Let us use a hypothetical example to illustrate the process. The Acme Corporation, a fictional product manufacturer, is involved in civil litigation. The case involves a former employee, John Doe. John filed a lawsuit against Acme alleging he was terminated as a result of age discrimination. John Doe, who is the plaintiff, hired a lawyer to represent him in his suit against Acme, the defendant. Acme also hired a law firm to represent it in the case. When the case reached the discovery phase, John's lawyer asked Acme for documents that related to John's termination. Acme's management, working with its lawyers, determined which employees had documents that related to his termination. It instructed specific employees to not discard the documents that related to the issues in the case. Acme's IT director worked with his management to determine the locations where electronic documents that related to the case were stored.

Now, let us walk through three variations of the Acme example at different points in time. In the first variation, Acme terminated John in 1990. In 1990, most companies did not have company-wide e-mail accounts or network servers. Wireless cellular telephones were just getting started and smart phones were still a science fiction concept. The computer systems at Acme, including those used by John and his management, were probably running MS-DOS or Windows 2.0 (the classic 286 PC). If Acme was on the cutting edge of computer technology in 1990, it may have had Windows 3.0, which ran on the 386 powerhouse. In order to respond to the John Doe lawsuit, Acme's management contacted the employees that may have had records that related to John's termination, including the personnel files from John's manager, the human resources (HR) files that related to John and Acme's employment policies. In order to find the electronic documents, Acme's management went to the IT director who managed all of Acme's computer systems. The IT director managed a relatively small system that included a mainframe computer system. The IT director worked with management to find material regarding John's case.

Now let us assume Acme terminated John in 2000. In 2000, Acme had been using e-mail for several years now and employees regularly use e-mail to correspond with each other to get their work done, including personnel matters. Acme had Windows 98 running on employees' desktops, which allowed employees to save documents, for example, in Microsoft Word, to their computers. Employees saved documents to the computers' desktops, local drives, and some network file servers. Acme's management followed a similar process for collecting the documents as it did in 1990. However, because the electronically stored information at Acme has multiplied since 1990, Acme's job to identify the relevant documents has become more complicated. Acme management asked various employees that worked with John, including his manager, to identify the documents that related to the case. It also worked with the IT director to understand how the computer systems were managed and how employees used those systems. Acme's cost associated with the discovery phase of the case has likely grown due to the increased volume of documents that Acme's lawyers needed to review and potentially produce to John's lawyers.

Finally, let us assume that Acme terminated John in 2007. Since 2000, Acme implemented several new technologies to help its employees be more productive and communicate faster. In 2007, Acme used Microsoft Vista with SharePoint. It had Microsoft Exchange 2007 with unified messaging (voice mail integrated into users' e-mail account). Many senior employees have wireless handheld devices that integrate into their e-mail accounts as well as instant text messaging. Acme employees use these new technologies and create more documents on their desktops and rely on electronic communication tools, including e-mail and instant messaging. In 2007, the IT director has to address a more complicated network of computer systems to help management identify those systems that contain documents that relate to John's lawsuit. As a result of the increase in the number of documents, Acme's costs associated with the discovery phase of the case is likely to be even more expensive and time consuming in 2007 than in 2000 due to the higher volume of electronically stored information.

Acme is certainly not alone. Companies all over the world are facing a new generation of technology as new employees, who have been teething on instant messaging, MySpace, and Facebook, join the workforce. For example, many companies convene meetings using Web-based electronic rooms, for example, WebEx, with shared desktops. These next-generation meeting rooms allow participants to attend meetings without ever leaving their desks, and many participants may never meet each other face to face.

Technology managers, like the IT director at Acme, may have a difficult task when they are asked to identify systems and electronically stored information that may contain documents relevant to a lawsuit. Additionally, the technology generation gap is often short relative to the time it takes for courts and litigators to deal with these new issues in actual cases. It can take years for a dispute to make its way into a courtroom. Technology managers are faced with making decisions about how to implement new technology tools without knowing what, how, or when they will have to produce documents in the future.

FEDERAL RULES OF CIVIL PROCEDURE

Companies that find themselves involved in civil litigation follow certain rules. If the case is in a federal court, they use the FRCP; if the case is in a state court, the parties follow the state's rules of civil procedure, which often follow, if not verbatim, the FRCP. Again, this chapter will not be an exhaustive review of the FRCP, but it will touch on a few rules that relate to electronically stored information.

On December 1, 2006, amendments to the Federal Rules of Civil Procedure were submitted by Congress and approved by the Supreme Court. The amended rules specifically address electronically stored information. Let us start with a rule that was not amended, FRCP 26(b)(1), which defines the scope and limits of Discovery.

- **Rule 26(b)(1): Discovery Scope and Limits***In General*. Parties may obtain discovery regarding any matter, not privileged, that is relevant to the claim or defense of any party, including the existence, description, nature, custody, condition, and location of any books, documents, or other tangible things and the identity and location of persons having knowledge of any discoverable matter. For good cause, the court may order discovery of any matter relevant to the subject matter involved in the action. Relevant information need not be admissible at the trial if the discovery appears reasonably calculated to lead to the discovery of admissible evidence. All discovery is subject to the limitations imposed by Rule 26(b)(2)(i), (ii), and (iii). (U.S. House of Representatives Committee on the Judiciary, 2006)

Now let us return to the Acme example. Why is Acme's IT director's job more complicated in 2007 than in 1990? I suggest to you that it is the result of the explosion of electronic documents, specifically e-mail and other documents stored on Acme's computer systems.

Below is a summary of the electronic-discovery amendments to the Federal Rules of Civil Procedure that this chapter will discuss.

- **Rule 26(a)(1)(B): General Provisions Governing Discovery; Duty of Disclosure; Required Disclosures; Methods to Discover Additional Matter**

A copy of, or a description by category and location of, all documents, electronically stored information, and tangible things that are in the possession, custody, or control of the party and that the disclosing party may use to support its claims or defenses, unless solely for impeachment. ("Law Library/Court Rules," n.d.)

What Might this Mean for Acme? When Acme's IT director reviewed this amended rule with management and outside lawyers, they discussed, among other things, the computer systems at Acme and thought about a summary of the electronically stored information, such as in databases, servers, and electronic archives, that may be relevant to John's case against Acme.

- **Rule 26(b)(2)(B): General Provisions Governing Discovery; Duty of Disclosure; Discovery Scope and Limits; Limitations** A party need not provide discovery of electronically stored information from sources that the party identifies as not reasonably accessible because of undue burden or cost. On motion to compel discovery or for a protective order, the party from whom discovery is sought must show that the information is not reasonably accessible because of undue burden or cost. If that showing is made, the court may nonetheless order discovery from such sources if the requesting party shows good cause, considering the limitations of Rule 26(b)

(2)(C). The court may specify conditions for the discovery. (“Law Library/Court Rules,” n.d.)

What Might this Mean for Acme? When Acme’s IT director reviewed this rule with management and lawyers, they discussed, among other things, what sources of potentially relevant electronic information that they thought were not reasonably accessible and that they did not intend to search. If John’s lawyer wanted Acme to provide documents from one of the sources that Acme disclosed as not reasonably accessible, then John’s lawyer could serve a motion to compel the production of information from the sources identified as not reasonably accessible. Acme will then have to explain why the information that John’s lawyer is seeking would require undue burden or cost to obtain.

Now let us look at another hypothetical exchange. John’s lawyer wants Acme to provide information from an old HR computer system that is no longer active, and Acme considers the old system not reasonably accessible because it would require the IT director to hire a specialized vendor to restore the old system. John’s lawyer files a motion to compel in order to obtain the information contained within the computer system. Acme’s IT director explained to the court that the request is unduly burdensome; specifically, it will cost Acme US$500,000 to restore the legacy computer system. Acme feels that the burden is excessive relative to the amount John’s lawyer is seeking in the case, which is only US$100,000 in money damages. The court will have to weigh these factors when determining whether to permit discovery.

- **Rule 34(a) & (b): Production of Documents, Electronically Stored Information, and Things and Entry Upon Land for Inspection and other Purposes; Procedure** (a) SCOPE: Any party may serve on any other party a request (1) to produce and permit the party making the request, or someone acting on the requestor’s behalf, to inspect, copy, test, or sample any designated documents or electronically stored information—including writings, drawings, graphs, charts, photographs, sound recordings, images, and other data or data compilations stored in any medium from which information can be obtained—translated, if necessary, by the respondent into reasonably usable form, or to inspect, copy, test, or sample any designated tangible things which constitute or contain matters within the scope of Rule 26(b) and which are in the possession, custody or control of the party upon whom the request is served;

  (b) PROCEDURE: The request shall set forth, either by individual item or by category, the items to be inspected, and describe each with reasonable particularity. The request shall specify a reasonable time, place, and manner of making the inspection and performing the related acts. The request may specify the form or forms in which electronically stored information is to be produced. Without leave of court or written stipulation, a request may not be served before the time specified in Rule 26(d). The party upon whom the request is served shall serve a written response within 30 days after the service of the request. A shorter or longer time may be directed by the court or, in the absence of such an order, agreed to in writing by the parties, subject to Rule 29. The response shall state, with respect to each item or category, that inspection and related activities will be permitted as requested, unless the request is objected to, including an objection to the requested form or forms for producing electronically stored information, stating the reasons for the objection. If objection is made to part of an item or category, the part shall be specified and inspection permitted of the remaining parts. If objection is made to the requested form or forms for producing electronically stored information—or if no form was specified in the request—the responding party must state the form or forms it intends to use. The party submitting the request may move for an order under Rule 37(a) with respect to any objection to or other failure to respond to the request or any part thereof, or any failure to permit inspection as requested. Unless the parties otherwise agree, or the court otherwise orders:

(i) a party who produces documents for inspection shall produce them as they are kept in the usual course of business or shall organize and label them to correspond with the categories in the request;
(ii) if a request does not specify the form or forms for producing electronically stored information, a responding party must produce the information in a form or forms in which it is ordinarily maintained or in a form or forms that are reasonably usable; and
(iii) a party need not produce the same electronically stored information in more than one form. ("Law Library/ Court Rules," n.d.)

What Might this Mean for Acme? When the Acme IT director reviewed this rule with management and lawyers, they likely discussed, among other things, the options regarding how they would produce documents for John's lawyers. They discussed an upcoming meeting between their lawyers and John's lawyers, during which they would discuss the form of the document production. The Acme IT director has already met with some vendors that provide specialized tools to assist with document productions. The IT director understands that John's lawyer may specify a form of production and if he does not, then Acme will have to produce the documents in the form they are ordinarily maintained at Acme or in a reasonably usable format. Let us assume John's lawyer agreed to accept a production of the relevant documents in Adobe's Portable Document Format (PDF). In addition, Acme provided an accompanying index of metadata including the date, title, author, recipient, document type, and extracted full text.

The amended federal rules have provided organizations and their IT departments with more instruction regarding electronically stored information. However, complying with the obligations associated with electronic discovery can be very difficult for organizations, even those with a modest technology portfolio. Organizations with newer generation technologies may find themselves in a much more complicated situation when faced with discovery in civil litigation.

In a recent *Richmond Journal of Law & Technology* article, Doug Rogers, citing the Sedona Principals,[1] stated "it is unreasonable to expect parties to take every conceivable step to preserve all potentially relevant electronically stored information":

For instance, a party should not have to preserve all possible sources of e-mail simply because it is possible that an existing or former employee, who claims she was harassed, may have forwarded an e-mail from her supervisor to other employees, or because one of the e-mails may have been exported into a .pst file outside of the e-mail folders in the cache of a computer.

Comment 5a to Sedona Principle 5 explains: The obligation to preserve relevant evidence is generally understood to require that the producing party make reasonable and good faith efforts to identify and manage the information that it has identified as reasonably likely to be relevant. Satisfying this obligation must be balanced against the right of a party to continue to manage its electronic information in the best interest of the enterprise, even though some electronic information is necessarily overwritten on a routine basis by various computer systems. (Rogers, 2008, p. 25-26)

Companies like Acme are not alone when working through these issues. Over the past few years, many specialized litigation support vendors have emerged that offer a variety of technology and process solutions to assist organizations and their IT departments in managing the discovery process. In July 2007, one such vendor, Autonomy, acquired another company, Zantaz, which is an e-mail archiving firm, for US$375 million. Soon after the Zantaz acquisition, Autonomy reported a US$70 million deal with an unspecified customer. The customer is believed to be a large global bank that is preparing for a wave of civil litigation in the wake of the subprime mortgage lending crisis. The value of this transaction, which is Autonomy's largest, is reported to be almost double Autonomy's average transaction with a single customer. If this type of transaction is any indication of future business, Autonomy could see a return on the Zantaz acquisition much faster than many anticipated (Mellor, 2008).

Companies and organizations around the world are evolving their technology footprints. Many commentators believe the volume of documents that employees create on new applications are also increasing at a rapid rate, some say exponentially. The legal environment is also evolving and new cases are emerging that deal with new issues regarding electronically stored information. One case that has gained some notoriety is the Columbia Pictures case (*Columbia Pictures Indus. v. Bunnell et al.*). In this case, Columbia Pictures was ordered to capture and preserve data stored in temporary random access memory (RAM), which is very volatile and can be overwritten by the computer system when shutting down, starting up, or simply opening and closing applications. Some commentators have stated that the judge's holding is limited to the specific facts at issue in this case and generally considered data in computers' temporary RAM to be excluded from discovery because they are so transitory (Jacoby, 2007). Some commentators have expressed that Rule 34, which describes "other data or data compilations stored in any medium from which information can be obtained," would not apply because the RAM data were not easily obtainable. In this case, however, the judge stated that the data stored in this computer system's RAM was "extremely relevant and may be key," and that it was not available anywhere else (Jacoby).

A notable distinction of the temporary, or ephemeral, data at issue in the Columbia Pictures case is the way the specified computer system was configured. Many computer systems use RAM as a memory buffer that will randomly (hence the name *random access*) write some data to help support the application. For example, take an ordinary desktop computer. When a user turns the computer on, the computer will allocate some RAM to support the operating system. If the user then opens Microsoft Word, the computer will allocate more RAM for the application and the associated documents that are open. If the user then opens Excel and closes Word, the RAM assigned to Word is sometimes overwritten in order for the computer to run Excel. The computer, during normal operation, will recycle RAM memory to whatever application(s) needs it. The information stored in RAM, if viewed by a human, would most likely appear as gibberish as it is bits and bytes of computer code that the computer uses to function properly.

Nevertheless, the computer systems at Columbia Pictures, based on its own testimony, had a logging feature that was turned off. The court ordered Columbia to prospectively activate the logging feature and that the prior deletion of RAM was not a violation of the preservation order in the case (Jacoby, 2007).

Instant Messaging is now a ubiquitous technology across grade schools, college campuses, shopping malls, and movie theaters (much to my chagrin). Instant messaging took off in the mid-1990s with the popular ICQ ("I seek you"). This was followed by AOL's Instant Messenger in the late 1990s. Today, there is a variety of open-source instant messaging, or text messaging, applications that run on desktop computers, mobile phones, and other wireless devices. Many instant messaging applications, especially those on mobile phones, are similar to RAM in that many of them do not keep a permanent log of past messages. Many mobile messaging devices keep messages for a short period of time, sometimes only minutes or hours, before they are overwritten or deleted.

IM is slowly invading the workplace. Instant messaging allows employees to communicate faster than e-mail and slightly slower than a real-time phone call. Users can carry on several conversations at the same time. They can create buddy lists, which allow for quicker communication as well as the ability to see if someone is online or not. In a *Wall Street Journal* online article, Mamberto (2007) cites a 2006 study of the American Management Association and the ePolicy Institute that found roughly one third of employees are using IM, many of them without their employers' knowledge. Many corporations and organization are reluctant to deploy IM systems due to security concerns, loss of productivity, and inappropriate use. Despite these reservations, Gartner, an IT research firm, predicts IM will dominate 95% of the workforce of large companies within the next 5 years (Mamberto).

Desktop-computer-based IM applications are slightly different than mobile-phone-based systems, notably with regard to storage. Many desktop-based IM applications provide options for longer term storage, similar to conventional e-mail systems. When Acme's IT director implemented desktop IM, he or she may have worked with the records, compliance, and law department to determine whether Acme needed to include a storage component in the event it would need to save some messages for a longer term purpose, either for business or litigation purposes.

Web 2.0 technologies, including IM, offer employees at large organizations instant access to colleagues across the organization. These technologies flatten out the hierarchical structure of many organizations. Andrew McAfee, associate professor at Harvard Business School, states employees "increasingly react to situations and problems on the fly, not solely by hierarchy" (Mamberto, 2007, p. 2).

The American Bar Association (ABA; American Bar Association Legal Technology Resource Center, 2008) cited a January 2008 *Detroit Free Press* report (Wendland, 2008) that IM text messages obtained from the offices of Detroit Mayor Kwame Kilpatrick suggested he had a 2-year affair with his chief of staff Christine Beatty. Over 14,000 text messages between Kilpatrick and Beatty, who were both married at the time, were exchanged that allegedly illustrated a sexual affair including during official business trips. The lawsuit, which was filed by a former police officer, alleged that he and another officer were fired in retaliation because of their role in an internal investigation that would potentially expose the mayor's affair. Mayor Kilpatrick testified that he did not have an affair with his chief of staff and that he did not retaliate by firing two police officers. The City of Detroit tried to avoid producing the damaging IM text messages, but eventually they were disclosed. The case eventually settled for US$8 million.

The ABA article (2008) further reported that an estimated 20 billion IM text messages are sent each month in the United States alone. The article cited a Gartner report, which estimated that 1.9 trillion text messages were sent worldwide in 2007. The report predicted a 19% increase to 2.3 trillion text messages in 2008. When Acme's IT director implemented desktop IM, he or she worked with the records, compliance, and law department to consider how to train employees on the proper use of IM, similar to the corporate e-mail system.

Blogs (Web logs), wikis (collaborative Web sites), and RSS (really simple syndication) are also on the rise within companies and organizations. These new technologies can offer significant advantages to organizations. Most of the advantages are in response to the limitation of e-mail. For example, a user can subscribe to relevant work sites using RSS feeds as opposed to relying on e-mails from colleagues. E-mail can be a very inefficient way to keep employees updated on a given topic because many employees will overuse the carbon copy (CC) function as a way to inform people on the distribution list. There are two problems with this technique. First, the person sending the message may not know all the people that really need to be informed of the topic. Second, many people on the distribution list may not even care about the message.

One of the advantages of RSS as a communication tool is that users can decide what they are interested in and will subscribe to those topic areas. The RSS technology will notify users of updates and direct them to the source of the information. Many of the RSS sites will keep track of the pages viewed so users do not need to worry about reading articles twice because it is tracked by the system ("The Logic of Blogs and Wikis in the Enterprise," 2005).

Now, let us return to the Acme example, specifically, a project to develop a new product. The Acme project team created an electronic workroom where project team members could save and update important documents related to the product. The workroom had several blogs and wikis for employees to discuss current issues related to the project, including materials, sales strategies, and budgets. Managers who were not working on the project day to day could use the RSS tool to subscribe to the workroom. The manager would be notified when new content had been added to the workroom on a specific topic.

Blogging is still a relatively new technology and companies are still learning and assessing the security risks related to employee blogging. John Browning (2007) of the *Houston Business Journal*, citing a 2006 survey of the Employment Law Alliance, found that about 5% of Americans have a personal blog, while only 15% of their employers have a blogging policy. Additionally, Browning stated that an estimated 27% of adults read blogs according to the Pew Internet and American Life Project. Employees may make seemingly innocent statements on a public blog that can put a company, and the employee, at great risk. For example, if one of the Acme employees working on the new product was at home spending time on a personal blog, he or she may post an entry about how great Acme is and that it has a great future—referencing the new product without actually mentioning it by name. The employee is a hardworking and dedicated individual who really believes in Acme and is proud to work there. The employee may not even have to mention the new product by name but could indirectly disclose trade secrets or forward-looking financial information that could be damaging to Acme. Before the lightening fast World Wide Web, an innocent comment to a neighbor in the driveway presented some risk to the company, but in the days of online blogs, where users from all over the world can easily search and find just about anything on anything, a seemingly innocent comment is now within infinitely greater reach. Again, the employee probably had no intention of making a public statement about Acme's financial future. Many companies have existing policies that govern employee communication, which would generally cover employee blogging. However, the Society for Human Resource Management reports that a small number (3%) of firms have implemented blogging policies specifically (Browning).

CONCLUSION

Employees are faced with new technologies every year, and the current wave of Web 2.0 technologies will soon be replaced with a new generation of tools that will enable employees to share information faster and easier. Information technology managers must make decisions regarding these changing technologies and must work with their management to assess the pros and cons of implementing them. Many IT managers realize that employees will create and store documents on these new systems and those documents may be needed for future litigation. Furthermore, as the overall volume of documents increases as a result of newer technologies, the overall cost to organizations will also likely increase due to the time and expense for lawyers to collect, review, and produce these documents in litigation. As the volume of discoverable electronically stored information grows, the real winners may be the specialized vendors, like Autonomy, that offer specialized document management and litigation support services to companies dealing with huge volumes of data. If the current data-growth trends continue, coupled with increased user adoption of Web 2.0 technologies, then companies, including their management, IT managers, and lawyers, will have a lot of work ahead of them.

ENDNOTE

1 The Sedona Principals: Best Practices, Recommendation & Principles for Addressing Electronic Document Production is a project of The Sedona Conference Working Group on Best Practices for Electronic Document Retention and Production. The Sedona Conference is a non-profit organization of lawyers, consultants, academics and jurist.

This work was previously published in Social Software and Web 2.0 Technology Trends, edited by P. Deans, pp. 68-78, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 1.12
The Power and Promise of Web 2.0 Tools

G. Andrew Page
The University of Alaska Anchorage, USA

Radwan Ali
Kennesaw State University, USA

ABSTRACT

The key idea that sets constructivism apart from other theories of cognition was launched about 60 years ago by Jean Piaget. It was the idea that what is called knowledge does not and cannot have the purpose of producing representations of an independent reality, but instead has an adaptive function (Von Glasersfeld, 1996, p.3). In this chapter, a variety of Web 2.0 applications and their affordances are presented and discussed in relation to constructivism in higher education. The aim is to explain how these applications can be used in higher education to promote interactive and engaging learning environments. Recommendations for harnessing the potential of these tools along with practical examples will assist facilitators of higher education with creative means to design their courses and thus promote Learning 2.0.

DOI: 10.4018/978-1-60566-654-9.ch010

WHAT IS WEB 2.0?

The Internet has presented great opportunity for global human participation by transcending geographical, cultural, religious, social classification, and political barriers. As the proliferation of learning with technology increases, there is also amplification in the array of technological possibilities for a variety of asynchronous and synchronous interactions. Therefore, it becomes necessary to provide insight into the effective use of these technologies and the facilitation of e-learning. According to Schrum and Hong (2002) the goals of teaching with technology should include facilitating higher-level, thinking skills, such as analysis, synthesis, and evaluation. Alexander describes this phenomenon:

Web 2.0 is defined as a way of creating webpages focusing on microcontent and social connections between people. It also exemplifies that digital content can be copied, moved, altered, remixed, and linked, based on the needs, interests, and abilities of users—quite against the grain of both traditional and recently expanded copyright (Alexander, 2008, p.151).

There are many creative Web 2.0 applications, tools, and services available online (See Appendix A for a list of digital resources and links). These tools or web-based learning objects have the potential to engage and involve the learner with technology as opposed to having a student learn from a computer module or digital lecture. There are many Web 2.0 tools that can be found at different sites on the web. For the purpose of this chapter, we will discuss blogs, wikis, widgets, nings, plugins, social networking (MySpace and Facebook), and virtual environments (Second Life). What issues will Web 2.0 solve? What are the potential learning outcomes from using Web 2.0? It is the promises of positive educational outcomes that web-based tools can potentially produce through quality interaction at a meta-level that are intriguing many educators and trainers.

This chapter has implications for instructors, students, instructional designers, and administrators involved with e-learning in higher education. This chapter also provides a synthesis of e-learning issues and an overview of Web 2.0 tools for promoting a constructivist environment.

The 5th edition of *The Principles of Instructional Design* (Gagne, Wager, Golas, Keller, 2005), states a very important instructional design question which is often overlooked. The question is "For what problem is instruction the solution?"(p.23). This question is especially relevant considering the numerous challenges and limitless potential of Web 2.0 tools. By using Web 2.0 tools the theory of constructivism can be applied to reach new levels of digital creation and e-learning.

Constructivism is the process of linking new understanding to old, modifying and enriching existing knowledge, and enhancing depth of comprehension about a topic. McFedries refers to Web 2.0 as functioning as a platform (p.68) because of the ability to delete, edit, and add content and work collaboratively with others in a synchronous approach.

"Constructivism affords a knowledge building process that engages active learners with the physical and social world" (Twomey-Fosnot, 1996, p.30). These interactive online tools include portals, blogs and video blogs, widgets, plugins, wikis, conferencing, games, survey instruments and games. Using these Web 2.0 tools in an educational setting builds on Vygotsky's (1978) view of interactive learning within the zone of proximal development (ZPD) and how the social process is crucial to the development of thought and behavior patterns. The application and integration of quality educational content is an important part of the constructivist framework. This is the adaptive function of constructivism alluded to by Von Glasersfeld (1996).

When interactive technology is applied in accordance with constructivist principles, it has been called "learning 2.0" (Brown & Adler, 2008). Learning 2.0 is about actively using technology. The multiliteracies of education (e.g., critical thinking, creating content, collaboration) are fostered due to the constructivist nature and exchange of knowledge that is part of the Web 2.0 phenomenon (Alexander, 2008). Learners taking the initiative to create content and learning by being engaged and involved is at the heart of constructivist practice. Brown and Adler (2008) acknowledge the impact of Web 2.0 and how it can add a new dimension to communication and participation:

The latest evolution of the Internet, the so-called Web 2.0, has blurred the line between producers and consumers of content and has shifted attention from access to information toward access to other people. New kinds of online resources—such as social networking sites, blogs, wikis, and virtual communities— have allowed people with common interests to meet, share ideas, and collaborate in innovative ways. Indeed, the Web 2.0 is creating a new kind of participatory medium that is ideal for supporting multiple modes of learning. (p.18)

THE USE OF WEB 2.0 APPLICATIONS TO PROMOTE CONSTRUCTIVIST LEARNING

This section will consider the benefits of constructivism and match them with the characteristics of a few of Web 2.0 applications. Constructivism, as a learning theory, provides an appropriate fit for the use of Web 2.0 applications. Constructivism as a learning framework can be served immensely by using the tools and affordances (Jonassen, 1999) presented by the Web 2.0 applications. Constructivism suggests that learners can enjoy their experience by being more involved in their learning than by being listeners (Franklin, 2000; Ge & Tok, 2003). The idleness or boredom aspects of passive listening prevent learners from realizing the potential of the subject matter being discussed. However, by engaging in relevant learning activities, the learner will have the opportunity to apply the concept learned. Web 2.0 applications can be very engaging for different reasons: the novelty of the technologies, the aesthetic appeal, and their interactive modes.

Web 2.0 applications present many affordances for constructivist learning. Some of these applications include social networking, blogs, podcasting, media sharing, and virtual worlds. The common trait of these applications is shareability. These applications and similar others allow for global interaction where participants contribute and use others' contributions. The contribution can be as simple as a few paragraphs posted to a blog or as complex as creating avatars on a Second Life (SL) island. The main premise is that these applications represent great potential for learning. In this section, a sample of five Web 2.0 applications is used to illustrate the use of Web 2.0 applications as contexts for constructivist learning. This sample includes social networking and bookmarking, blogs and wikis, podcasts, and media sharing, and virtual worlds

Blogs have been around for several years and we are seeing the impact of their use for positive learning outcomes. Basically, blogs are web-based journals that allow participants to contribute to or create discussion threads. The threads can discuss different subjects separately or concurrently. There are possibly millions of blogs on the web whose subjects include religion, politics, medicine, and car repairs in addition to others. Blogs are characterized by their asynchronous nature and ease of use. However, they also provide opportunities for audio and video files. Blogs can be used for constructivist learning in many ways. First, a blog can serve as an individual learning journal. A learner may start a blog to keep inventory of his/her learning. This inventory will help learners build from one phase of their learning to another. By doing so, learners use previous knowledge to generate new insight. Another example of a blog being used for educational purposes is a class group project. Learners can be engaged with discussion topics and debates in a flexible learning space that allows for the incorporation of videos, graphics, and audio and the enhanced creativity. Blogs are user-generated web-based journals that offer opinions and information and that may include text, images, and links to other blogs and web pages. Some blogs are confined to personal expressions, but others make provision for reactions and comments from readers. In higher education, blogs have been used as a means by which students can collaborate asynchronously. A blog can also serve as a group knowledge builder. A group of learners can join forces in order to complete tasks or projects. Each user is usually assigned a section of the task to complete and contribute to the blog. Through this collaboration, useful content is usually produced as a solution for the task or project. The produced content is presented as the fruition of the learning experience. By collaborating with others, a learner can be benefit by adding to his/her knowledge through the different members' contributions.

A wiki is a collaborative website that allows visitors to add, remove, edit, and change content, typically without the need for registration. It also allows for linking among any number of pages. This ease of interaction and operation makes a wiki an effective tool for mass collaborative authoring. (e.g., Wikipedia.org). Similar to blogs in many aspects, Wikis can serve numerous constructivist learning opportunities such as content production. Wikis are made of many web pages that allow contributors to add and modify content, theirs and others'. The modification opportunities make it possible for all wiki members to share their knowledge in addition to assessing that of other members. By assuming the editor (modifier) role, a wiki contributor is improving his/her writing and critical thinking. Through this practice, new knowledge may be found and added to the learner's previous knowledge. The aggregation of faculty publications in a wiki is described by Conner (2007) as a means to socially construct an online library resource and promote research productivity.

An example of an educational wiki in higher education would be Ask Dr. Wiki (http://www.askdrwiki.com/). This is a medical wiki devoted to creating a free source of medical information. Individuals can publish clinical notes, pearls, X-ray images, angiograms and more on the site. Using this wiki, anyone with a medical background can contribute or edit medical articles.

Media Sharing and Construction

Podcasts and media sharing include video, audio, photos, slides, and others to present other constructivist learning opportunities through producing and sharing digital content. Media sharing is appealing because of its interactive and personal nature. The content can be audio or video files. The main premise here is that learners can generate new knowledge by creating these podcasts and learn from the creation process. Through podcasts, learners can share information and broadcast many useful materials. Learners, then, can use podcasts as tools to learn from and teach others and provide follow-up on previous discourse. Dearstyne (2007) notes the trends in collaboration such as the increase in blogs, mashups, and wikis. Mashups are websites, or other applications, that integrate and aggregate content from more than one source into an integrated application (e.g., combining data on a topic of interest with geographical data such as Google Maps).

Virtual worlds applications such Second Life are interactive environments where participants assume personalities (avatars) to interact with other individuals and objects such as rooms, documents, presentations, and videos. By interacting with the different objects, a learner will gain a bit of knowledge from each object and then connect these different bits from the different objects to form the new experience. Similarly, the virtual world setting provides group collaboration contexts, and consequently, opportunities for constructing content. The application of collaborative and social constructivist-oriented activities, such as virtual spaces and a "user-centric approach" that promotes higher level learning are described by Sommerville and Nino (2007). The social synchronicity achieved through these media allows distant learners to connect in real-time and promote connectedness and community.

The group experience and the community membership provide positive confines that embrace collaboration and individual creativity. While the participants are making products, they will have opportunities to acquire and gain feedback from other community members (Jonassen, 1999). That will provide the different participants with new skills and knowledge as benefits of the feedback. These applications present opportunities where a learner can physically actively engage through the human computer interface (HCI) technology, virtually, and mentally active. An example of how a learner can be physically engaged in a virtual environment (and arguably a web 3.0

phenomenon) is in the work of Mitch Kapor and Philippe Bossut (2008) who have developed a hands-free navigation device for SecondLife. A video of this prototype is available at: http://www.youtube.com/watch?v=2t52gkAwJq8

Consequently, by being mentally active, learners will expand their cognitive abilities to move beyond memorization. Within that practice, long-term critical thinking becomes the norm for these learners. Furthermore, as the learners' critical thinking evolves, a few positive habits such as planning and organization are gained. These habits become second nature for these learners in their potential careers. Web 2.0 activities are similar in those regard. For example, learners who use blogs to track their learning (writing) and to collaborate with others (building camaraderie) will develop better writing and interpersonal skills to help in their respective careers. The main point is that many of these learning experiences are transferrable, and can be potentially helpful in many different contexts.

Perhaps the most important aspect of constructivism is that learners are charged with their learning. That charge will breed a sense of ownership and accordingly, learners become more interested in the process. Similarly, Web 2.0 applications encourage all participants to create their own work that can be seen by millions around the world and have the potential for cross-hemispheric collaboration. Because they own that work and the fact that it is in the public spotlight, those participants become more motivated to do work of high quality. There is an interesting dynamic and digital responsibility that is inherent to content creation on the web. The participants will seek and explore new venues and resources from which to learn to make better products. These results contribute to personal involvement. Furthermore, the experience will generate a long-term memory of the new knowledge and skills that are gained (Doolittle, 1999).

Another significant aspect which relates Web 2.0 applications to constructivist settings is that designing and implementing authentic activities to which the learners can relate can be a great motivation for the learner to participate (Zaulkernan, 2006). That authenticity can pique the learners' interest and curiosity. For example, the use of podcasting and vodcasting (video casting) by music students enhances the learning experience and enables the transmission of content to mobile devices (m-Learning) such as iPods and cell phones.

How will a facilitator use the different Web 2.0 applications as contexts for constructivist learning experiences? This question should be considered in relation to learning objectives, activities, and outcomes.

Implementing Web 2.0 technologies, while establishing learning objectives, is the beginning in creating a constructivist approach to learning. To accommodate for the potentially different levels of motor skills among the learner, the facilitator must include learning the technology as one of the learning objectives of the learning experience. By doing so, the learner will understand the importance of these technologies for completing their tasks. For example, a facilitator may create a list of learning objective as shown below in Table 1 to promote Learning 2.0.

Accordingly, the activities in the same learning experience should be planned to help the participants use the respective Web 2.0 technologies while completing their tasks toward achieving the learning outcomes. In order to apply an activity to achieve Learning Objective 5, a facilitator may require the learners to find a blog and monitor the interaction or to set up an RSS feed to manage the flow of created content. Furthermore, the learners are asked to explore how to participate in the respective blogs they found. Since participation is multi-layered the teacher could also encourage the participants to use other Web 2.0 technologies on the blog such as widgets or avatar creation (meez.com). Assessments of the participating learners should include measure to assess whether they learned and used the respective Web 2.0 technolo-

Table 1. An example of implementing Web 2.0

The learners will be able to
1. Identify what a learning strategy is.
2. Explain what a lesson plan is.
3. Create a lesson plan.
4. Explain what a blog is.
5. Use a blog to post his/her lesson plan.
6. Provide and receive feedback.

gies. Using survey instruments such as Zoomerang or SurveyMonkey can provide feedback to faculty about the level of learning.

WHY ADOPT WEB 2.0 TOOLS?

There are numerous benefits of using Web 2.0 tools: access to social networking tools, knowledge sharing, digital publishing, and cost effectiveness, are just a few. *Computerworld* magazine (2008) reports that Web 2.0 tools such as wikis, blogs, and social networks are being used by many corporations (e.g., Intel Corporation) to solve complex problems, to promote training, and to build an online community. Higher education is also using these emerging tools in creative ways to promote a higher quality of interactivity and collaboration among learners. Palloff and Pratt (2005) discuss the idea that teaching and learning involve more than taking old teaching models of lecture and transferring them to a different medium. They describe an engaged learner who collects, create, and recreates knowledge. The definition of dialogue is enhanced to included Web 2.0 tools such as blogs, synchronous audio and video conferencing. Social constructivist theory emphasizes the negotiation of meaning and construction of shared understandings through dialogue (Jonassen, Davidson, Collins, Campbell, & Haag, 1995; Bonk & Kim, 1998).

There are numerous issues with the quality of online or blended learning courses, including how course objectives are accomplished, and the levels of interaction with content, peers and the instructor (Legon, 2007). *Can Web 2.0 tools increase the Zone of Proximal Development (ZPD)?* Research centered on making the transition to the Web 2.0 world and the use of podcasting audio technologies to promote collaborative learning uncovered some interesting findings. Lee, Mcloughlin and Chan (2008) found that students were empowered by the creation of rich content, as was evident in their own reflections and analysis of constructivist thought. However, Sandars and Schroter (2007) surveyed 3000 medical students and found that while there was a high familiarity and interest with a wide variety of Web 2.0 technologies, there was hesitancy in how to use these technologies. The authors conclude that there needs to be additional training in the instructional approaches for achieving desired educational outcomes through the power of technology.

The increase of online interactivity through these tools offers solutions to communicating ideas collaboratively not only effectively and efficiently, but also with a high degree of creativity. Interactivity is complex and important to the learning process. There is interactivity between the learner and the teacher, the learner and peers, and the learner and the technology. Woo and Reeves (2007) deconstruct the notion of interaction in online learning through the social constructivist lens and show how it can promote meaningful learning. They conclude:

The bottom line is that to increase the learning effects of online interaction, we should, first of all, understand clearly the nature of interaction within the framework of social constructivist learning theory. Once we gain such an in-depth understanding, we should be able to engage in productive research and development to identify the necessary design principles for implementing more effective interaction activities within web-based learning environments. (p.23)

Likewise, according to Jonassen (1995), constructivists use technologies for purposes that are (1) applied to real-world situations, (2) problems and constructs, and (3) authentic and appropriate social context. There are numerous benefits to integrating the Web 2.0 tools as learners are empowered through the creation of content and the many forms of communication. What are some of these Web 2.0 tools and how are they being used in higher education?

WEB 2.0 AND HIGHER EDUCATION

Thompson (2007) reasoned that "Today's institutions of higher education (IHEs) need to consider how they can move from being Education 1.0 institutions because their competitors are revising how they provide services and coursework using Web 2.0 applications" (p.40). However, Eijkman (2008) believes that ". . . the effective educational use of Web 2.0 will in due time lead to a radical reframing of our educational thinking and practices and a redesign of digital learning spaces around interdependent acculturation . . ." (p. 102). From the standpoint of the learner, Karpinski (2008) found that a majority of learners surveyed were unfamiliar with Web 2.0 resources. While students may be familiar with the Web 2.0 tools there was hesitancy on their part to adopt them because of (1) difficulty of use (2) skepticism about the quality of content, and (3) the lack of perceived need. Clearly there needs to be more of an acculturation of Web 2.0 tools so that current and future educators can be more confident in effectively using them in their practice. In some cases there will be a need for an epistemic instructional transformation for faculty who are in various stages of adopting new technologies.

Campus Technology magazine published an article in April 2008 about creative ways that college instructors have integrated these tools into their practice. Examples include the use of a wiki that allows students to submit exam questions for consideration. A portal is a system that has many functions including serving as an online community and a means to catalog or organize different digital creations and provide them to members in an effective manner.

Alexander (2006) describes Web 2.0 tools and how this "heterogeneous mix of relatively familiar and emergent technologies" (p.33) is used in a social networking context. Another similar example is the University of Alaska Anchorage's Web 2.0 wiki which not only defines what a Web 2.0 tool is but how this online learning instrument can be used in an educational setting. Graduate students enrolled in an instructional design course collaborated to create the content on the wiki. Each learner was given editor status so that they could post their content defining and describing the technology but also sharing their creativity by sharing how they used the tool for a positive learning outcome.

In addition to the most popular (blogs and wikis), other Web 2.0 tools include social bookmarking (de.li.ci.ous), collaborative webpage design (jot.com), and (Gnosh.org). Wix.com is a free online tool that helps the web designer with the development of a Flash interface website. This intuitive tool offers "what you see is what you get" (WYSIWYG) design that is dynamic and fluid.

Conferencing software is a tool that allows for the synchronous sharing of ideas. Commercial products include HorizonLive, Elluminate, and Adobe Breeze. WizIQ is a free online conferencing software which provides the interactivity of a whiteboard, webcam, direct messaging, and more, (http://wiziq.com). Understandably, Alexander concludes: “Meanwhile, academic implementations are bubbling” (2006, p.44) with the advent of Web 2.0.

While there have been studies on interactivity and collaborative learning through community building (e.g. Davies, Ramsay, Linfield, & Couperthwaite, 2005; Palloff & Pratt, 2005; Sherry, 2000), Hung (2001) contends there still remains much research on *how* the social interactions that are an inherent Web 2.0 component support the Vygotskian claim that cognition begins at the social level. What does this mean in terms of utilizing Web 2.0 technologies for facilitation of Learning 2.0? What is the educational utility of the Web 2.0 tools?

THE OPPORTUNITIES OF WEB 2.0

The purpose of this section is to convey how Web 2.0 applications represent and provide opportunities for constructivist learning. The capacity to apply and construct new knowledge, to encourage critical thinking, promote collaboration, and to use guided scaffolding to support higher level thinking and learning is at the very center of the constructivist paradigm. It has been argued that higher education needs to move “beyond the individual mind to include learning that is built up by mediated conversations among members of peer groups, local learning communities, and broader cultural systems” (Sherry, 2000, p. 21). Conrad and Donaldson (2004) also take this point of view: “Engaged learning stimulates learners to actively participate in the learning situation, and thus gain the most knowledge from being a member of an online learning community” (p.7). Lave and Wenger (1991) state: “A learning curriculum is not something that can be considered in isolation, manipulated in arbitrary didactic terms, or analyzed apart from the social relations that shape legitimate peripheral participation” (p. 97). But what is meant by “actively participate” and which technologies and approaches support positive learning experiences and promote quality interaction or legitimate peripheral participation?

Social Networking

Social networking Sites (SNS) applications allow participants to belong to “friends” communities where individuals are invited to be friends. Two well-known applications are MySpace and Facebook. On the other hand, social bookmarking applications are used to help users organize information by saving different web sites in one location because the user deems these web sites important for learning and research. Tufekci (2008) did a study on social networking sites (SNS) by college students and draws an important distinction between the “expressive Internet” with an emphasis on the social interactions and networking and the “instrumental” Internet that focuses on e-commerce and news. Users of SNS are also much more frequent users of the expressive Internet.

Global access and democracy can easily intertwine to create new possibilities. For example, what if classrooms in Tasmania were paired with their counterparts in Alaska to study polar science from an Antarctic and Arctic perspective? The learners could collaborate to write and illustrate a report that could involve topics such as global warming, environmental, or ecological science. The learners could communicate through web-based synchronous and asynchronous mediums.

The Internet has made digital space and the ZPD much larger and the world much smaller. Two video game players can enjoy the same game via separate individual web access points without regard to their location or time zone; that is the larger space. These games can be embedded within a blog, webpage, or wikis (See, for example, http://onlinegames.net for the extractable and embeddable code). With the possibility that one of these players may be in the USA and other may be in China, the world reach becomes smaller. The world of Web 2.0 applications such as MySpace (http://www.myspace.com/) and FaceBook is also small; through them, a person may have hundreds, if not thousands, of friends around the world. These and similar social networking applications make global interaction and cross-hemispheric collaboration easier and provide settings for global communities.

Another example of a Web 2.0 tool that promotes interactivity and community is the Ning. A Ning aggregates Web 2.0 tools such as a webpage discussion forum, file sharing, within its multi-functional framework. While MySpace and Facebook have been used for several years, a Ning allows the user to create their own network and not just be a participant in a network that has already been created. It is a means by which private or public groups with a shared interest can construct digital space and interact through a variety of mediums online. The Ning at http://Classroom20.ning.com is an example of constructed digital space for educators who can share how they are integrating technology into their practice. It is a dynamic community that is changing because of the content constructed by participants. Nings have been created for a myriad of groups including those focused on action research, Scholarship of Teaching and Learning (SoTL), computer enthusiasts, history buffs, etc. It takes only a few minutes to construct a Ning and create a viable network that aggregates the virtual social presence of learners, their thoughts and discussions, and digital artifacts. The Ning has enormous potential for providing structured community and while it is in its early stages of development it has been widely adopted by higher education departments, workgroups, ESL classes, significant interest groups, and so on.

Web 2.0 tools support many forms of social networking and collaboration, including those which a more revolutionary sense of emancipatory Freirean education, such as Flash mobs, groups that get together physically to demonstrate or protest using digital technologies (e.g. LiveJournal.com). There are countless possibilities.

Widgets and Plugins

Other tools include widgets or interactive add-ons to supplement the learning experience. These widgets can be embedded into course blogs to achieve a variety of results. There are numerous widgets to help with the learning of language and testing of skills on a variety of topics, from tracking the financial markets, to creating artwork like Matisse. A good example of a widget used in education is to have it deliver course content that the students can embed in their individual web sites. Various widgets include embedded videos, photos, podcasts, maps, all aggregated on one page (pageflakes.com) (*The Chronicle of Higher Education*, 2008).

Web 2.0 tools may fill a specific need or address a certain problem, such as the management of the enormous amount of digital information. For example, a pragmatic plug-in tool for browsers is Real Simple Syndication (RSS). RSS feeds allow the user to aggregate various resources (e.g. blogs, wikis libraries, periodicals, websites) when new content has been added. Another example is Zotero, a free plug-in for anyone who needs assistance when managing reference data from online database searches. It helps organize the citations of research articles and makes the writing experience flow easier because the knowledge can be arranged, classified, and shared. It also facilitates the importing and exporting of information. For example, you can capture citations from webpages, store documents, images, and other indexed citations from large databases. The user has the ability to co-create digital libraries and be notified via Really Simple Syndication (RSS) when a relevant research publication is tagged for retrieval from similar articles. Filters can also be set up for advanced searches. Users can also write annotations that will be saved with each reference.

FUTURE TRENDS

The question "What issues will Web 2.0 address?" was asked earlier in this chapter. The new approaches to learning with digital media have the potential to enhance the higher education learning experience. We are at the nexus of a historic transformation in how learning is shared, transmitted, collected, and constructed. The social web has seen a profound shift in higher education and the building of community through virtual social networking sites. As the facilitation of online learning evolves (artificial intelligence and non-human facilitation, web 3.0?) it becomes necessary to adopt Web 2.0 tools in the design of effective and efficient e-learning.

CONCLUSION

This chapter discussed the promise of using Web 2.0 technologies to extend the classroom. Some of the advantages associated with implementation of Web 2.0 were listed and discussed. The potential for a revolution of learning that involves constructivism will inherently involve these tools. "Constructing an understanding requires that the students have opportunities to articulate their ideas, to test those ideas through experimentation and conversation, and to consider connections between the phenomena that they are examining and other aspects of their lives" (Julyan & Duckworth, 1996, p.58). We can use these Web 2.0 tools to transform our practice and enhance the reality of learning. The dialectic between the individual and society through the use of Web 2.0 tools is expanding dramatically as these new possibilities suggest that learning is a constructive building process of meaning-making. Faculty should adopt these constructivist tools or run the risk of "engage or enrage" (Prensky, 2005). Faculty cannot continue to teach as they were taught but rather they must employ the interactive Web 2.0 tools to engage learners. This is the power and promise of Web 2.0 tools.

Chapter 1.13
Integrating Web 2.0 Technologies within the Enterprise

R. Todd Stephens
AT&T Corporation Collaboration & Online Services, USA

ABSTRACT

This chapter examines the elements of the new Web 2.0 technology base and reviews the lessons learned when implementing these technologies. Collaborative applications have made enormous inroads into the enterprise and bring unprecedented speed and transparency to communications. Researchers and practitioners alike are focusing on how collaborative applications can replace the one-way communications inherent to Intranet sites. This chapter is intended for individuals who are looking toward the possibility of integrating these new technologies into the core communication medium. Unfortunately, there are still large barriers such as politics, turf battles, integration, and poor usability with the current product set. A company's ability to manage information effectively over its life cycle, including sensing, collecting, organizing, processing, and maintaining information, is crucial to the long term success in a global economy. The success or failure of this integration may very well create or lose a competitive advantage for the enterprise. What is missing is a framework or roadmap in which organizations can plan out their execution of We 2.0 deployment.

DOI: 10.4018/978-1-60566-106-3.ch037

INTRODUCTION

Enterprises are being transformed from an old business model built around the command and control aspects information management to a new one where collaboration is the essential component. We are witnessing this transformation outside the enterprise with the success of Web 2.0 technologies like Wikipedia, YouTube, and Flickr. Yet, within the walls of the organization, progress is slow. This chapter will examine why the adoption rates for Collaborative and Social Software are low and what can be done to improve them. This research emerges from three Fortune 500 companies which the resulting methodology has worked to increase the adoption rates ten fold.

Traditional implementation methodologies focused on the hardware, software, and the associated functionality. Our research indicates that while these are important they do not lead to mass adoption of the application by the enterprise. Many functions that information workers perform are dictated by the business and current transactional systems like CRM, ERP, or accounting systems. Collaboration and Social Software need to be integrated as situational applications and although they are optional, they are required to reach higher levels of performance. Members of complex teams are less likely to utilize collaborative tools in the absence of other influences such as executive encouragement, modeling collaborative behavior, creating a “gift” culture, training, supporting a strong sense of culture, assigning team leaders, building, and understanding roles (Erickson & Gratton, 2007). Our research indicates barriers to adoption including social issues, cultural issues, awareness issues, educational issues, and political issues. This research will focus on the awareness and educational issues since most organizations implementing Web 2.0 will face these first issues first.

BACKGROUND

Web 1.0 Intranets

The term Web 1.0 emerged from the research around Web 2.0. Basically, Web 1.0 focused on a read only Web interface while Web 2.0 focuses on a read-write interface where value emerges from the contribution of a large volume of users. The Internet as well as the Intranet initially focused on the command and control of the information itself. Information was controlled by a relative small number of resources but distributed to a large number which spawned the massive growth of the Web itself. Like television, the Web allowed for the broadcasting of information to a large number of users.

Inside the organization, the Intranet has changed the way organizations structure and operate their business. Specifically, the Intranet has centralized communications and corporate information as well as built a sense of community across organizational boundaries (McNay, 2000). Typical organizations will have office-based employees in various locations, telecommuting, and off-shoring staff. The traditional day by day communication landscape has changed from personal to electronic. The migration to electronic communications emerged as standards, technology and infrastructure matured. This allowed more information sharing and community building to occur without a requirement of physical location. Over the past several years Intranets have emerged as the key delivery mechanism for application and business information. Intranets may be thought of as providing the infrastructure for intra-organizational electronic commerce (Chellappa & Gupta, 2002). This allows organizations to utilize the technology to achieve its organizational goals and objectives. Web 1.0 allowed the organization to govern the information flow and focus on achieving the business goals.

Unfortunately, most technologies fail to deliver competitive advantages over an extended period of time. Investments in information technology, while profoundly important, are less and less likely to deliver a competitive edge to an individual company (Carr, 2003). This is especially true in the world of the Web 1.0 since much of the knowledge and information is disseminated all over the world as quickly as it gets published. Organizations are beginning to see that the command and control model is no longer effective at developing a high performance work force which opens the door for the next evolution in technologies as described by the Web 2.0 framework.

Web 2.0 Defined

While Web 2.0 has been debated by researchers as to who and when the concepts emerged, little argument exists that the technology and demand has arrived. Unlike Web 1.0, this new technology encourages user participation and derives its greatest value when large communities contribute content. User generated metadata, information, and designs enable a much richer environment where the value is generated by the volume of employees. Sometimes referred to as sharing, collaboration, aggregate knowledge, or community driven content, social software creates the foundation of collective intelligence (Weiss, 2005). Much of the Web 2.0 technology is difficult to nail down with an exact definition; the basic truth is that Web 2.0 emphasizes employee interaction, community, and openness (Millard & Ross, 2006). Along with these characteristics, Smith and Valdes (2005) added simple and lightweight technologies and decentralized processing to the mix. O'Reilly (2005) defined Web 2.0 as a platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually-updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an "architecture of participation," and going beyond the page metaphor of Web 1.0 to deliver rich user experiences. While Web 2.0 has many and often confusing definitions most include the concepts of Weblogs, Wikis, Really Simple Syndication (RSS) Functionality, social tagging, mashups, and user defined content.

Weblogs or Blogs

Weblogs or blogs have become so ubiquitous that many people use the term synonymous for a "personal Web site" (Blood, 2004). Unlike traditional Hypertext Markup Language (HTML) Web pages, blogs offer the ability for the non-programmer to communicate on a regular basis. Traditional HTML style pages required knowledge of style, coding, and design in order to publish content that was basically read only from the consumer's point of view. Weblogs remove much of the constraints by providing a standard user interface that does not require customization. Weblogs originally emerged as a repository for linking but soon evolved to the ability to publish content and allow readers to become content providers. The essence of a blog can be defined by the format which includes small chunks of content referred to as posts, date stamped, reverse chronological order, and content expanded to include links, text, and images (Baoill, 2004). The biggest advancement made with Weblogs is the permanence of the content which has a unique Universal Resource Locator (URL). This allows the content to be posted and along with the comments to define a permanent record of information. This is critical in that having a collaborative record that can be indexed by search engines will increase the utility and spread the information to a larger audience. With the advent of software like Wordpress and Typepad, along with blog service companies like blogger.com, the weblog is fast becoming the communication medium of the new Web.

Sample Weblog URLs

- Andrew McAfee Web 2.0 Blog (http://blog.hbs.edu/faculty/amcafee/)
- Randy Basler's Boeing Blog (http://boeingblogs.com/randy/)
- Jonathan Schwartz's Sun Blog (http://blogs.sun.com/jonathan/)
- Rough Type by Nicholas Carr (http://www.roughtype.com)

Wikis

A Wiki is a Web site that promotes the collaborative creation of content. Wiki pages can be edited by anyone at anytime. Informational content can be created and easily organized within the wiki environment and then reorganized as required (O'Neill, 2005). Wikis currently are in high demand in a large variety of fields, due to their simplicity and flexibility nature. Documentation, reporting, project management, online glossaries, and dictionaries, discussion groups, or general information applications are just a few a examples of where the end user can provide value (Reinhold, 2006). The major difference between a wiki and blog is that the wiki user can alter the original content while the blog user can only add information in the form of comments. While stating that anyone can alter content, some large scale wiki environments have extensive role definitions which define who can perform functions of update, restore, delete, and creation. Wikipedia, like many wiki type projects, have readers, editors, administrators, patrollers, policy makers, subject matter experts, content maintainers, software developers, and system operators (Riehle, 2006), all of which create an environment open to sharing information and knowledge to a large group of users.

Sample Wiki URLs

- Wikipedia (http://www.wikipedia.org/)
- Reuters Financial Glossary (http://glossary.reuters.com/)
- Internet 2 (https://wiki.internet2.edu/confluence/dashboard.action)

RSS Technologies

Originally developed by Netscape, RSS was intended to publish news type information based upon a subscription framework (Lerner, 2004). Many Internet users have experienced the frustration of searching Internet sites for hours at a time to find relevant information. RSS is an XML based content-syndication protocol that allows Web sites to share information as well as aggregate information based upon the users needs (Cold, 2006). In the simplest form, RSS shares the metadata about the content without actually delivering the entire information source. An author might publish the title, description, publish date, and copyrights to anyone that subscribes to the feed. The end user is required to have an application called an aggregator in order to receive the information. By having the RSS aggregator application, end users are not required to visit each site in order to obtain information. From an end user perspective, the RSS technology changes the communication method from a search and discover to a notification model. Users can locate content that is pertinent to their job and subscribe to the communication.

Sample RSS URLs

- Newsgator (http://www.newsgator.com/)
- FeedBurner (http://www.feedburner.com/)
- Pluck (http://www.pluck.com/)
- Blog Lines (http://www.bloglines.com/)

Social Tagging

Social tagging describes the collaborative activity of marking shared online content with keywords or tags as a way to organize content for future navigation, filtering, or search (Gibson, Teasley, & Yew, 2006). Traditional information architecture utilized a central taxonomy or classification scheme in order to place information into specific pre-defined bucket or category. The assumption was that trained librarians understood more about information content and context than the average user. While this might have been true for the local library with the utilization of the Dewey Decimal system, the enormous amount of content on the Internet makes this type of system un-manageable. Tagging offers a number of benefits to the end user community. Perhaps the most important feature to the individual is able to bookmark the information in a way that is easier for them to recall at a later date. The benefit of this ability on a personal basis is obvious but what about the impact to the community at large. The idea of social tagging is allowing multiple users to tag content in a way that makes sense to them; by combining these tags, users create an environment where the opinions of the majority define the appropriateness of the tags themselves. The act of creating a collection of popular tags is referred to as a folksonomy which is defined as a folk taxonomy of important and emerging content within the user community (Ahn, Davis, Fake, Fox, Furnas, Golder, Marlow, Naaman, & Schachter, 2006). The vocabulary problem is defined by the fact that different users define content in different ways. The disagreement can lead to missed information or inefficient user interactions (Boyd, Davis, Marlow, & Naaman, 2006). One of the best examples of social tagging is Flickr which allows user to upload images and "tag" them with appropriate metadata keywords. Other users, who view your images, can also tag them with their concept of appropriate keywords. After a critical mass has been reached, the resulting tag collection will identify images correctly and without bias.

Sample Social Tagging URLs

- Flickr (http://www.flickr.com/)
- YouTube (http://www.youtube.com/)
- Del.icio.us (http://del.icio.us/)
- Technorati (http://technorati.com/)

Mashups: Integrating Information

The final Web 2.0 technology describes the efforts around information integration or sometimes referred to as "mashups." These applications can be combined to deliver additional value that the individual parts could not deliver on their own. One example is HousingMaps.com that combines the Google mapping application with a real estate listing service on Craiglists.com (Jhingran, 2006). Other examples include Chicagocrime.org who overlays local crime statistics onto Google Maps so end users can see what crimes were committed recently in the neighborhood. Another site synchronizes Yahoo! Inc.'s real-time traffic data with Google Maps. Much of the work with Web services will enable greater extensions of mashups and combine many different businesses and business models. Organizations, like Amazon and Microsoft are embracing the mash-up movement by offering developers easier access to their data and services. Moreover, they're programming their services so that more computing tasks, such as displaying maps onscreen, get done on the users' Personal Computers rather than on their far-flung servers (Hof, 2005)

Sample Mashup URLs

- Housing Maps: (http://www.housingmaps.com/)
- Chicago Crime (http://www.chicagocrime.org)
- Healthcare Product (http://www.vimo.com/)
- Global Disease Map (http://healthmap.org/)

User Contributed Content

One of the basic themes of Web 2.0 is user contributed information. The value derived from the contributed content comes not from a subject matter expert, but rather from individuals whose small contributions add up. One example of user contributed content is the product review systems like Amazon.com and reputation systems used with ebay.com. A common practice of online merchants is to enable their customers to review or to express opinions on the products they have purchased (Hu & Liu, 2004). Online reviews are a major source of information for consumers and demonstrated enormous implications for a wide range of management activities, such as brand building, customer acquisition and retention, product development, and quality assurance (Hu, Pavlou, & Zhang, 2006). A person's reputation is a valuable piece of information that can be used when deciding whether or not to interact or do business with. A reputation system is a bi-directional medium where buyers post feedback on sellers and vice versa. For example, eBay buyers voluntarily comment on the quality of service, their satisfaction with the item traded, and promptness of shipping. Sellers comment about the prompt payment from buyers, or respond to comments left by the buyer (Christodorescu, Ganapathy, Giffin, Kruger, Rubin, & Wang, 2005). Reputation systems may be categorized in three basic types: ranking, rating, and collaborative. Ranking systems use quantifiable measures of users' behavior to generate and rating. Rating systems use explicit evaluations given by users in order to define a measure of interest or trust. Finally, collaborative filtering systems determine the level of relationship between the two individuals before placing a weight on the information. For example, if a user has reviewed similar items in the past then the relevancy of a new rating will be higher (Davis, Farnham, & Jensen, 2002).

SAMPLE USER CONTRIBUTED CONTENT URLS

- Amazon.com (http://www.amazon.com)
- Ebay (http://www.ebay.com)
- Trip Advisor (http://www.tripadvisor.com/)
- Review Centre (http://www.reviewcentre.com/)

Web 1.0 Compared to Web 2.0

While the differences between Web 1.0 and 2.0 are grey at best, we can attempt to draw some segmentation by reviewing the high level characteristics. Table 1 provides a side by side comparison of these technologies.

In the Web 1.0 environment, information was largely static and controlled by a few resources. Specifically, the individual or organization that produced this information pushed information to the end user by either controlling the access or limiting the feedback options. Web 2.0 turns that model around and create a far greater dynamic environment where each consumer has the ability to contribute to the overall value of the information itself. Instead of searching and browsing topics, Web 2.0 users are allowed to publish and subscribe to the content which results is a more bottom up implementation. The following section will review how these new technologies can be integrated into the current knowledge environments that have traditionally followed the command and control model of information.

Enterprise 2.0

Enterprise 2.0 is a term used to describe the integration of the Web 2.0 technology portfolio inside of the organization. Both the producers and

Table 1. Characteristics of Web 1.0 and Web 2.0

Web 1.0 Characteristics	Web 2.0 Characteristics
Static Content	Dynamic Content
Producer Based Information	Participatory Based Information
Messages Pushed to Consumer	Messages Pulled by Consumer
Institutional Control	Individual Enabled
Top Down Implementation	Bottom Up Implementation
Users Search and Browse	Users Publish and Subscribe
Transactional Based Interactions	Relationship Based Interactions
Goal of Mass Adoption	Goal of Niche Adoption
Taxonomy	Folksonomy

consumers of the information will reside inside the organization. If either of the customer classifications involve outside entities then the Web 2.0 tag should be used. McAfee (2006) indicates a new wave of business communication tools which allow for more spontaneous, knowledge-based collaboration. These new tools, the author contends, may well supplant other communication and knowledge management systems with their superior ability to capture tacit knowledge, best practices and relevant experiences from throughout a company and make them readily available to more users. For all its appeal to the young and the wired, Web 2.0 may end up making its greatest impact in business. And that could usher in more changes in corporations, already in the throes of such tech-driven transformations as globalization and outsourcing. Indeed, what some are calling Enterprise 2.0 could flatten a raft of organizational boundaries; between managers and employees and between the company and its partners and customers (Hof, 2005).

Barriers to Adoption

This chapter does not address issues around infrastructure or software selection. The research wanted to look at the barriers to adoption assuming all other variables are constant and normally taken into account on most implementations. The following barriers of adoption are not related to the specific technology. Rather, they focus on the end user and the major issues impacted them. This makes sense in Web 2.0 the end user contributes as much to the success of the implementation as any other component.

Awareness Issues

The awareness issue describes an environment where of the majority of users have never heard of Web 2.0, Enterprise 2.0, Collaboration, and Social Software. More importantly, end users have not heard of the internal product offering, if one exists. Communication is one of the most critical aspects of letting people know that a collaborative or social application is available. Traditional information technology solutions were focused on a single business process and the aspects of marketing and branding were unnecessary. However, for enterprise services this awareness can be one of the most critical functions performed early in the product's life cycle. Like e-mail and desktop Office applications, you want a high degree of awareness across the entire enterprise. A high degree of awareness would be some where between 90-100 percent of the information workers within the organization.

Educational Issues

End users may have heard of Web 2.0 through the media but they still not understand how the technology can be used in a business setting. Once an end user becomes aware of an application, the next phase is to ensure that they understand how the application should be used. The educational area is critical since most employees above the age of 35 have not used these new types of technologies.

Cultural and Social Issues

When organizations have overcome the awareness and educational gaps, then we can make the statement that the majority of the organization knows the technology is available and what can be done with it. They may still choose to use their older technology that has been used in the past. Not with standing political pressure, we are looking at cultural or social issues. These issues can emerge when end users fear change, afraid of new methods, or prefer to work in a command and control model.

Political Issues

The final area focuses on the political pressure organizations place on users. Political pressure may focus around strategic direction, vendor associations, or organizational structures. In smaller organizations, these issues may not be as big an impact as in a large distributed environment.

INTEGRATION OF WEB 2.0 TECHNOLOGIES

The studied organization is a Fortune 500 telecommunications company that has gone through several acquisitions over the past few years. With the integration of three companies, the presented framework went through several different field trials over the course of three years. This allowed the research to apply the framework into three different companies in order to test the validity in a real business environment. The framework was developed after five years of trials in traditional knowledge management systems. The application of the framework to collaborative tools started in 2004 and progressed through 2007. The initial deployment focused on Microsoft's Sharepoint which is a collaborative tool that has most of the Web 2.0 elements described in the prior section. (See Figure 1.)

Common Situation

While all three implementations varied by size of the firm, number of employees, and basic infrastructure, the implementations had one common characteristic. Flat line growth occurred within six months in each of the deployments. Flat line growth occurs when new orders show no growth over a three to six month period. Figure 2 provides the different site metrics collected prior to the implementation of the proposed framework. The lines have been cut off to indicate the point in time the framework was applied to the organization.

In all three cases, the program had a solid beginning but reached a level of saturation between 90 and 120 collaborative sites. For clarity, the number of collaborative sites continued to grow but could not outpace the same number of deletions. A deletion occurs when a program, project, or resource no longer needs the collaborative or social software environment. On average, the leveling off of site demand occurred between five and six months.

Figure 1. Adoption rates prior to implementing the framework

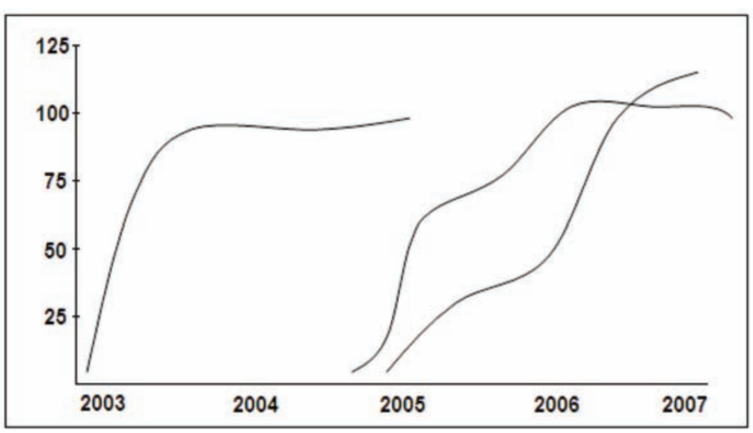

Figure 2. Implementation business model

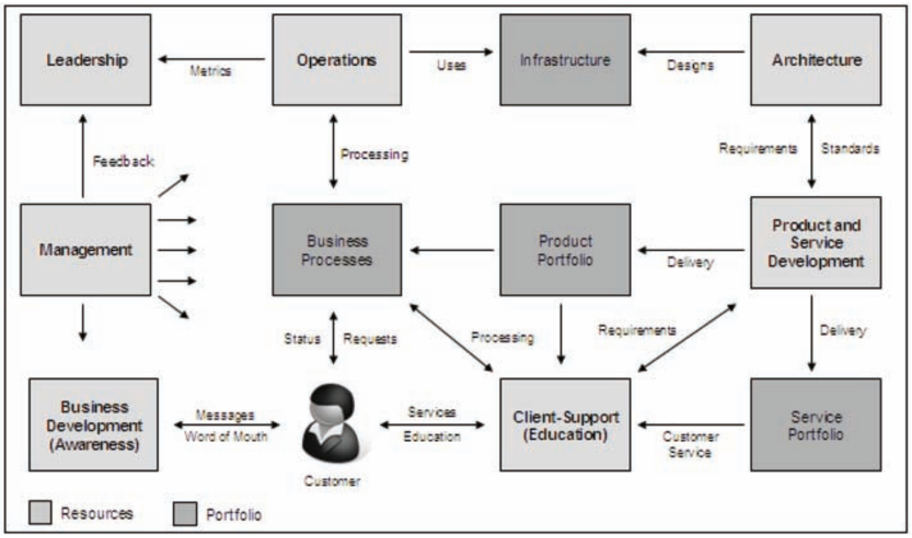


Business Model Framework

At the highest level, a business model is how an organization creates value. Timmers (1998) define a business in respect to the architecture for the product, service, and information flows, the benefits for the various actors, and the sources of revenue. In reality, an organization can have a variety of business models, each is simply an artificial representation of reality which detracts focus from certain aspects while concentrating on others (Kittl, Petrovic, & Teksten, 2001). This research uses the concepts of a business model, not in terms of commerce, but focused on the various interacting parts required to deliver business value. Figure 2 provides an overview of the business model used to describe functional designation of work. Some researchers refer to this as the resource model.

The model describes seven functional areas and four portfolio or product areas. Leadership and management are two functional areas that will not be covered in this chapter to any depth. The basic idea is that all information technology activities would include coordination, communication, and cooperation activities which are usually performed by these two groups.

Starting at the top of Figure 2, traditional implementations of information technology would include the operational and architecture functions. Operations would include activities such as hardware monitoring, software installation, backup, recovery, security, and maintenance. Computer Operations is a critical function to ensure delivery of a reliable, scalable, and functional infrastructure. This area must be governed with a high degree of control in order to maintain the stability of the environment. Architecture focuses on the design, planning, and software selection within the enterprise. Generally speaking, architecture includes the activities of defining and modeling the environment which may include the following architectures: business, application, data, information, technology, and product architecture (Pereira & Sousa, 2004). Traditionally, these components focused on ensuring that the environment did not fail from an infrastructure point of view. The vast majority of Web 2.0 implementations will focus on these core elements to ensure that the program operates effectively. The idea of an implementation failing would indicate the hardware or software failed to deliver the business value consistently over time. The problem with this approach is that having a perfect infrastructure does not guarantee mass adoption which is the truest measure of success. In the case of internally developed Web 2.0 applications or the utilization of open source, the architecture area could be expanded to encompass the entire System Development Lifecycle (SDLC).

We can define success (mass adoption) from two perspectives. In any knowledge type of application, you will have two key customer classes: the producer of the information and consumer of the information. The producer is the person, community, or application that creates a reusable asset in the form of information utilizing the Web 2.0 tools. This might include a wiki page or ownership to a specific weblog. The consumer is responsible for locating and accessing the information, assessing the ability to reuse the information, adapting to the information and integrating the information into the business. The consumer might not actually contribute to the environment in the form of comments or informational update. Production rates for Web 2.0 applications are still relatively low as compared to the number of users that consume the information. In one survey, only 11 percent of respondents would even consider contributing to Wikipedia while the actual number of contributors is less than 1 percent overall. When you have millions of consumers, a 1 percent contributor rate is pretty good. However, in an enterprise of 20,000 people that would indicate you will only have 20 contributors. This demonstrates the criticality of building up a producer community towards the long term goal of mass adoption. Not only do we need to focus on the information contained within the environment but also with the utilization of that information. The content must be used and to a greater degree, the utilization of the content drives the return on investment. This is not a trivial point; organizations must focus on the components of success and understand that having great hardware, software and functionality is simply the price of entry into the Web 2.0 environment.

Business Development

Located at the bottom right side of Figure 2 is the representation of the customer which could either be the producer or a consumer of the information. The overall framework centers around the customer behavior. The box on the left represents the functions of business development which we can define as any activity that impacts awareness and education before someone becomes a customer. Like the business functions of marketing, branding, and selling, business development strives to encourage participation. The ultimate goal is to ensure that every person in the enterprise knows these tools exist, understand how they can be used, and knows where to go to get engaged.

Client-Support

The vast majority of information workers are not familiar with virtual solutions and need guidance on how to best utilize and integrate this technology into their day to day operations. End users will ask five basic questions of the collaborative environment:

- What collaborative products and services are available to me?
- How can I utilize these products and services within my environment?
- Who can help me in case I need some professional guidance?
- Are the collaborative applications ready for enterprise usage?
- How am I doing in comparison to others or against best practices?

In order to address these questions, organizations should look toward developing a support group that can enable the end user rather than hindering their understanding of a collaborative environment. Meeting the needs of the customer may vary depending on the level of knowledge the user brings to the environment. Customers who are new to technology expect a high level of reliability and support in order to gain the greatest value possible (Johnston & Supra, 1997). Customer service should not be homogeneous and both the online and physical support environments need to take into account the experience level of the end user (Dutta & Roy, 2006). The customer wants to know what products, services, and documentation are available to them within the collaborative environment. The content of an online environment is not limited to the product or services provided. Rather, content includes the solutions and strategies employed to make it easy for the user to accomplish important tasks, such as information retrieval, search, and obtaining feedback (Calongne, 2001). Support information or content should include the product and service quantity, quality, and relevance to the customer (Palmer, 2002). Technologists often make the mistake of assuming a certain level of expertise with the user community. Unlike e-mail or Office products (Word Processing or Spreadsheet), collaborative tools are fairly unknown to the end user. A Client-Support environment would include many of the following components:

- Training and Education
- Subject Matter Expert Information
- Technical Supports and Operational Information
- Best Practices and “How To” Documentation
- Community of Practice
- Ordering Processes
- Product, Service and Solution Overviews
- End User Metrics of Content and Usage

Product and Service Development

Normally when you discuss the concepts around a product, you think of products like Microsoft’s Sharepoint, Confluence, Social Text, or IBM’s Connections. These could be considered products from an architecture or operations point of view. However, from the customer perspective these are tools. A product solves a problem or generates value based on the consumption or utilization. In other words, the product is what you can do with the tool. Products in the Web 2.0 space include weblogs, wikis, collaborative intranets, virtual workspaces, RSS feed readers, book marking, and professional profiles. Each of these can be categorized as a product regardless of the tool selected to perform the function. Services would include both tangible and intangible value-add activities that go along with the products. Services might include templates, user guides, editing, PDF conversion, education, and training. Services must be delivered to the customer and cannot be inventoried for later use. Taken together, products and services provide the customer experience that encourages participation and end user involvement.

Portfolios

Not counting the infrastructure, the model identifies three additional portfolios including the product portfolio, the service portfolio, and the business processes. The product portfolio would include the various products developed in the prior section. Since most products are meta-physical in nature, they must be demonstrated in the online support environment. The service portfolio will describe the services available to the end user. The idea is that products must be demonstrated while services must be described. Finally, the business process portfolio defines the business processes required to engage in the environment. Taken together, a customer may engage with several products, services and business solutions which constitute a solution offering. Assuming the ultimate goal of any Web 2.0 application is the mass adoption of the customer base then you want to move up the value chain. The value-chain has been well documented by Joseph Pine II and James H. Gilmore.

Pine and Gilmore (1997) discuss "the experience economy" by tracing the value added to the coffee bean in its various iterations from pure "commodity" to pure "experience." In their evolutionary construct there are four stages, in ascending order of sophistication the stages are commodity, good, service, experience. They point out that coffee is traded on the futures market at roughly $1 a pound (thus, about 2 cents a cup at the "commodity" level). After manufacturers roast, grind, package and distribute the bean for retail, the price jumps to between 5 and 25 cents a cup (the "goods" level). At a "run-of-the-mill" diner a cup might run from 50 cents to $1 a cup (the traditional "service" level). The authors contend that one can "Serve that same coffee in a five-star restaurant or espresso bar, where the ordering, creation, and consumption of the cup embodies a heightened ambience or sense of theatre, and consumers gladly pay anywhere from $2 to $5 for each cup." Thus, by creating value at the "experience" level, the seller is able to charge an extremely high premium over that charged by the "service" provider. In defining their terms they argue that, "When a person buys a service, he purchases a set of intangible activities carried out on his behalf. But when he buys an experience, he pays to spend time enjoying a series of memorable events that a company stages, as in a theatrical play, to engage him in a personal way." The idea is that organizations that support the Web 2.0 implementation must move up the value chain in order to obtain the mass adoption

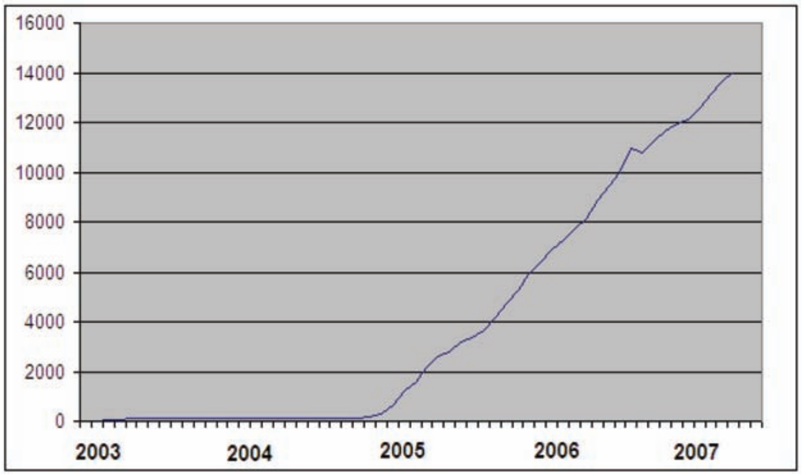
Field Trials

The first implementation of the framework occurred in 2004. As seen in Figure 1, the deployment had already reached the point of saturation when executive leadership contacted the author's team to see if the framework could be applied to the Web 2.0 area. In the past, the framework had been successfully implemented in knowledge management type implementations. These systems included prior research in metadata repositories, registries, and other knowledge applications. Focusing on the left most line (Figure 1), demand had leveled off at around 100 collaborative environments with an average monthly variance of +/-5 percent. The initial review and prioritization of activities focused on providing the online support environment, automating the procurement process, and developing marketing plans. These were seen as obvious gaps in the prior implementation model based on the author's observations. The author was also able contact various user communities in order to ascertain if these gap assumptions were true. No official survey was used to collect the information other than informal conversations. Figure 3 provides the results of implementing the framework over a 36 month period of time.

By the fall of 2007, the studied organization had over 13,000 collaborative sites with an average monthly growth rate of 423.62 percent. As the implementation matured, less focus was placed on the business opportunity area and more on the client-support area. This would make sense, since the number of employees that utilizing the collaborative environment was around 95 percent of the employee population. That is to say that 95 percent of the employees had heard of and used some form of the application which was determined by the unique user id logged into the system.

In 2006, the studied organization was purchased by a larger telecommunications company.

Figure 3. Collaborative sites after the framework application



This purchase brought together three different companies, all of which had an implementation of the collaborative suite. The adoption rates were similar to those found in Figure 1, represented by the two lines located on the right side of the chart. Executive leadership reviewed the implementations and determined that the framework needed to be applied in the other two companies as well. The initial step would be to survey the new organizations to see where the issues lie in adoption and determine which parts of the framework should be emphasized. Unlike the first field trial, the author had no insight into the new companies prior to the integration.

Survey Tool

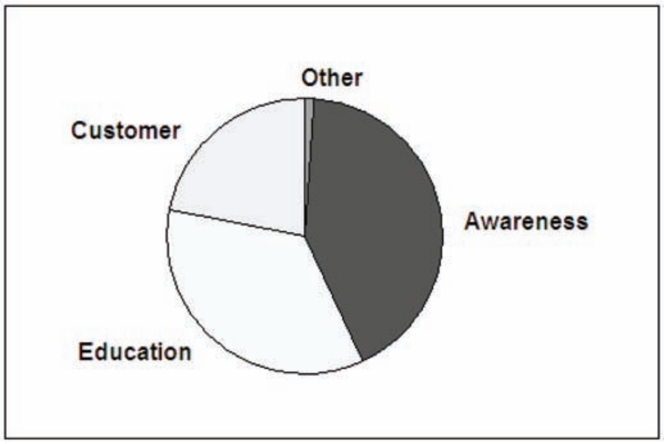
An employee survey was used to determine which of the adoption barriers were prevalent. Based upon some initial interviews, the survey was distributed via e-mail, and incentives were used to encourage participation. One hundred employees were randomly selected from the corporate directory. Two follow up e-mails were used to encourage users to participate and the average return rate was 72 percent. The questions on the survey included the following:

1. Have you ever heard of Collaborative or Social Software? (Determine Awareness)
2. If you have heard of these, does your organization utilize them? (Cultural, Political, or Social)
3. What is the primary use of the Collaborative and Social Tools within your organization? (Education)
4. Please describe your overall impression (use, purpose) of the products in a few sentences?
5. Please describe your experience with these tools in a few sentences (accessed infrequently, heavy user, loved it, etc.).

Notice that no specific questions were asked to differentiate between the cultural, political or social barriers. The reason for this was that the percentage was expected to be low as compared to the other issues of awareness and education. In order to ensure the survey group didn't know Collaborative and Social Software by other names, a product matrix was included that showed the specific products like Sharepoint, Confluence, or Open Source. The results of the surveys are presented in Figure 4.

The surveys were issued in January of 2007

Figure 4. Survey results (percentage)



and September of 2007. The first response to the survey showed an enormous awareness issue in which the vast majority of end users had not heard of the social offering or did not understand how the tool could be used. Over 77 percent of the respondents indicated that the lack of awareness or education was the primary reason for not implementing collaborative solutions in their environment. Only 2 percent acknowledged the actual use of the tools during the few years and the remaining 21 percent focused on the cultural, social and political issues. This result would indicate the need to address the awareness and educational issues first.

Field Trials II, III and IV

Based upon the results of the survey, awareness and education were identified as the two main issues. The user community simply did not know the tools existed or how they could be used in a business environment. The current deployment could easily be expanded to the new organizations will very little effort. For example, the community of practice was expanded to include the new organizations as was the ordering process replicated across all three companies. The client-support was centralized as a one stop location for the end user community to obtain information and support in a self service fashion. The results of these field trials showed a dramatic increase in demand in just a few months. On average, the new organizations increased by 1,608 percent and 78 percent respectively. Key actions by the implementation team included the following:

- Expanded the Client-Support environment to include all three organizations
- Expanded the product offering (new releases, Web components, and applications)
- Expanded the service offering for additional training, education, and consulting
- Developed new reward and recognition programs
- Published articles in various organizational newsletters
- Posted to the corporate weblog and wiki daily
- Developed audio and video training programs
- Consolidated business process into a single customer experience
- Expanded the Community of Practice (CoP)
- Developed additional audio and video programs for awareness and education

- Integrated with other Collaborative tools like Podcasting, Audio Conferencing, Instant Messaging, and Social Software
- Celebrated Key Milestones like the 25,000th Collaborative Environment

At the time of this writing, the total number of collaborative sites had grown to over 28,000 with 2-3 million page views per month. The number of document objects exceeded 2 million. An additional survey was conducted in late 2007 which was similar to the one described earlier. The awareness and education problem of 77 percent had dropped to 33 percent within the nine months of implementing the framework.

The final field trial occurred in mid 2007 with the deployment of Social Software which included weblog, wiki, and book marking applications. The major difference in this effort was that the framework was applied from the beginning. Similar activities were performed including adding an online client-support environment, training, education, marketing, and extending the offering with additional products and services. Within 4 months, the total number of information points exceeded 5,500.

CONCLUSION

In this chapter, we have laid a framework to support the implementation of collaborative and social software. As discussed, users come to this technology with a wide variety of experience levels which cannot be assumed by the technology community. Client-support must be implemented if the business wants universal adoption and a high degree of business value. The different components of the framework address the concerns of the end user which can put them at ease and create a more open environment for integrating this new technology. The framework focused on the issues with awareness, education, and the offering. By addressing these components, organizations will focus their resources on the components that define a successful implementation. The results of the field trials indicate that within any environment or culture, mass adoption can be obtained. With mass adoption, the return on investment of these technologies will be high.

KEY TERMS

Client-Support: Client-Support is a term used to describe the various efforts to ensure the success of an environment. These efforts would include education, training, communities of practice, online documentation and automated business processes for procurement.

Collaboration: Collaboration is defined as people working together on non-routine cognitive work. This activity is about behavior, work habits, culture, management, and business goals and value generated we people from diverse backgrounds come together.

Information Worker: The information worker is a label placed on individuals that primarily work with information and data. Information workers perform non-routine, cognitive, or creative work that often requires both structured and unstructured information inputs from multiple sources.

RSS: In the simplest form, RSS shares the metadata about the content without actually delivering the entire information source. An author might publish the title, description, publish date, and copyrights to anyone that subscribes to the feed. A feed reader application is required just as an e-mail client is required to read e-mail.

Social Tagging: Social tagging describes the collaborative activity of marking shared online content with keywords or tags as a way to organize content for future navigation, filtering, or search.

Weblog: A blog (short for weblog) is a personal online journal that is frequently updated and intended for general public consumption. Blogs are a series of entries posted to a single page in reverse-chronological order. These original entries cannot be edit by others but can be commented on by anyone.

Web 2.0: Web 2.0 is a term used to decribe the next generation of Web applications where information flows both from the producer as well as from the consumer. Additionally, Web 2.0 embraces more of a thin client architecture which allows for the assembly of various components. Together, end user conent and thin client applications make the Web 2.0 environment.

Wiki: A wiki is software that allows users to easily create, edit, and link pages together. Unlike a blog, the end user can actually update the original authors information.

Chapter 1.14
Security in a Web 2.0 World

Richard T. Barnes
SunGard Higher Education, USA

ABSTRACT

Web 2.0 has brought enumerable benefits as well as daunting problems of securing transactions, computers, and identities. Powerful hacker techniques, including cross-site scripting (XSS) and cross-site request forgery (CSRF), are used to exploit applications to reveal and steal, at the worst, confidential information and money, or, at the least, cause trouble and waste time and money for reasons that may be best described as fun or simply possible to do. The people interested in transgressing Web 2.0 applications do so for money, prestige, or for the challenge. An infamous hacker from the early days of the Internet now heads his own Internet security company. A more recent hacker of some infamy has created a stir of concern and consternation as to how pervasive and potentially destructive hacker attacks can be. Securing Web 2.0 applications requires a multifaceted approach involving improved code development standards, organizational policy changes, protected servers and workstations, and aggressive law enforcement.

DOI: 10.4018/978-1-60566-122-3.ch005

INTRODUCTION

With the multitude of benefits derived from the various Web 2.0 technologies, it is unfortunate that this book needs a chapter on security. Although the collaborations, synergies, and transformations of the collective Web technologies (known as Web 2.0) have immeasurably changed society in a good way, there is a bad element that we must recognize, understand, and defend against.

The relatively open and participative nature of Web 2.0 is, at once, a strength and weakness. Opening sites to user content and comment creates synergies that would not exist had the sites been restricted to a select few. However, it is difficult to restrict user input to only positive discourse; various motivations compel some to poison this well we know as Web 2.0.

Collectively, the responsibility and burden falls on organizations and individuals to share in constraining the enablers to minimize the damage to our 2.0 Web sites. Although it is helpful to understand the motivations behind the various (and growing) attacks, it is more important to follow best practices in code development and security design (Evers, 2007). The adage "the best defense is a good offense" does not apply well to Web 2.0 security. We cannot proactively prosecute and punish someone before they commit a Web attack; we may be on the road to a changing world, but constitutional rights cannot be trampled upon.

It is likely that some are dissuaded by the possibility of punishment if caught; but if only a few carry out Web attacks, our best approach, still, is to mount our best defense. It is of course equally important to prosecute security offenses. The threat of punishment has to be more than theoretical: Offenders must know that if they are caught, there will be consequences.

This chapter will explore the motivations, methods, and defenses against the malicious behaviors that cost time and money, and lessen the positives that can come from these technologies. There have been notable attacks to prominent Web sites; a few of these will be examined for their causes and associated effects. The evolution of the World Wide Web into version 2.0 has had social impacts, too. What are these impacts, and are there trends evident that may help us predict where security attacks and defense strategies will go in the future? Some possibilities are explored here and in subsequent chapters.

There is an old adage that says those who forget the past are condemned to repeat it. This idea cannot be forgotten in Web 2.0 security. We must remember how attacks happened before so we can avoid similar attacks in the future. By examining the trends, analyzing our mistakes, and understanding our needs, we can improve on Web 2.0 and make it better. That is how we got to version 2.0 from 1.0. Perhaps, as the Web evolves into what some in the community are calling Web 3.0, the lessons learned here will not be forgotten.

BACKGROUND

It is perhaps ironic that the following definition for application security comes from one of the best known wikis, Wikipedia. Application security encompasses measures taken to prevent exceptions in the security policy of an application or the underlying system through flaws in the design, development, or deployment of the application. This definition is an excellent start in addressing a very large problem. However, it does not really tell us why; that is, why is it necessary to prevent exceptions to security policy?

A broader definition may help. There are several definitions of the word *security*: The freedom from danger or the freedom from fear and anxiety are two variants that tell us why application security is so important to Web 2.0 applications. Identity theft, corporate espionage or sabotage, and/or simple maliciousness are certainly enough to give most of us some pause or anxiety. Application security, as it relates to Web 2.0, is now an area of great attention because of our collective need to be free of these dangers.

A confluence of factors has complicated our lives as Web 2.0 becomes a more significant presence. The graphics-rich functionality, collaboration, and opportunities have not only yielded "serendipitous innovation" (Tapscott & Williams, 2006), but less desirable consequences, too.

Consequences such as cross-site scripting (XSS) and cross-site request forgeries (CSRFs) were not anticipated when foundational Web 2.0 technologies were created. Asynchronous JavaScript and XML (extensible markup language), or AJAX, is a set of Web development techniques that enable Web sites to be interactive and rich with features that make the static Web pages of a few years ago seem, well, static. However, it is through AJAX and other technologies that Web attackers have created innovative ways to, at the least, cause mischief, and at the worst, cause severe harm.

The subject of Web 2.0 security has a number of important acronyms; AJAX is one. Others include XML, RSS (really simple syndication), and SOAP (simple object access protocol; Shah, 2006). This chapter is not necessarily intended to define and explain these terms, but more to put them in context with the larger problem (and challenge) of Web 2.0 security. Much of the recent literature talks of where the burden lies: with the developers, with the companies, and with the users. The reality, however, is that at least some of the burden falls on each of us.

Developers can build security into the applications they write instead of adding security later as an afterthought. Companies can elevate security to an enterprise-level initiative and build it into the products they sell. Although companies have been victims of security incursions, especially of late, the user has often been victimized, and it is often at the user level where good security hygiene is easiest and best applied.

A comprehensive approach to securing Web 2.0 applications stands the greatest chance for success. It is not enough to say that developers need to do a better job or companies cannot rush products to market when everyone can contribute to better security. How ironic that one of the great strengths of Web 2.0, collaboration, can, in effect, help solve one of its greatest weaknesses!

SECURITY PROBLEMS AND WEAKNESSES

AJAX in this context is not a cleanser made famous by a television jingle, nor is it a reference to the Greek who out of madness quite literally fell on his sword. AJAX in this context is a programming technique that employs a few other successful technologies including, as the acronym implies, XML and JavaScript (O'Reilly, 2005). Seen as an essential enabler of the Web 2.0 era, AJAX serves as the technical nexus for the development of the rich, interactive Web sites that we now take for granted. Capable of making direct communication with the Web server, AJAX Web sites can request server data without reloading the Web page. These behind-the-scenes data exchanges occur without the user's knowledge and provide a transparency to applications that make them distinctly more advanced than their Web 1.0 predecessors.

This direct communication between the Web server and Web application also provides an opening for application security transgressions (Enright, 2007). One method of attack, known as XSS, involves the injection of malicious code into a Web page viewed by others. The silent (i.e., hidden) execution of the AJAX code is perhaps one of the biggest areas of concern for IT security experts. Because transactions are occurring in the background without the user's knowledge and input, the potential for the execution of malicious code running unimpeded is large. This code may run on the computers of unsuspecting Web site visitors, exposing the visitors to the possible theft of sensitive information (e.g., banking information, authentication credentials, etc.). There are several types of XSS attack methods; however, the common denominator in the end result is that the user's browser always executes code that is, at least, not authorized, and at worst, destructive or compromising (McMillan, 2007).

Attacks using the CSRF method have been less common, but a large unrealized potential exists for more attacks (and more harm) in the future. The *cross-site* in CSRF is derived from the XSS method explained above and denotes some of the similarities between the two methods. Where the two methods are most different can be denoted in the *forgery* part of the name. According to Merriam-Webster Online, a forgery is defined as an imitation passed off as genuine. This is quite literally what the CSRF attack method does: Unauthorized (or forged) commands from a user are transmitted to or from a trusted Web site. The reliance and trust on an established (authenticated) identity is how the Web has worked, and the CSRF method exploits this common characteristic by imitating the authenticated user (Waters, 2007).

XML poisoning is another method of attack. Web 2.0 applications transmit XML data between the client and server as part of their normal operations. Although poisoning may sound a bit overstated, the method will corrupt (or poison) the XML data in such a way as to disrupt the processing of the information. The effect of this poisoning can range from denial of service (DoS), where the targeted server is bombarded with spurious requests that will, in effect, bring the server down or render it nonfunctional, to compromised confidential information.

RSS is a method and an XML 1.0-compliant format that aggregates disparate sources of Web information into a feed for the user. The user subscribes to the feed and sets the criteria for what information should be included (or excluded) in the feed. While this may sound like an incredible time saver for the user, what it also can do is expose the user to malicious code embedded in the source information. This code may also be aggregated along with the legitimate information, and the user will not necessarily know anything is amiss. This RSS injection method, as it is known, can install and launch software on the user's computer, potentially compromising confidential information.

Web services can be a fertile ground for Web 2.0 security intrusions. SOAP is the common protocol used for Web services remote procedure calls, and is therefore an often-used method for attack. Parameter manipulation and node exploitation are common techniques used in Web-services-related attacks. In parameter manipulation, the variables that are passed in services calls can be manipulated to suit the attacker's needs. If a site has insufficient validation of received parameters, the site is open to attack and compromise. Nodes on the Internet cannot be assumed to be secure: If a node is compromised, a SOAP message en route can be intercepted and modified as part of an attack. Although there are several variations on the Web services theme, these types of attacks are less prevalent than the JavaScript-based attacks.

WHO ARE THE ATTACKERS, AND WHAT ARE THEIR MOTIVATIONS?

Just as Web applications have evolved from the static, even boring presentation of webmaster-defined content, so too have the people who stage attacks on the Web. Because *evolution* may imply betterment, perhaps it is incorrect to say that attackers have evolved; what has really happened is that their methods have become more sophisticated as the Web infrastructure has become more complex. But, who are the attackers and why do they do what they do?

There are no clear definitions or labels for these Web attackers. While the word *hacker* has been generally used in a pejorative sense by the media, there are other words that may be more precise. The word *cracker*, also known as a black hat, refers to a person who illegally compromises the security of a computer system or network to reach a malicious end. A white hat will (attempt to) compromise security, but will also have valid permission from the system or network owners; the objective, of course, is to locate security holes and plug them before they are exploited. Not to imply a standard curriculum has been established, but to acquire the necessary skills to be a cracker, one should first be a hacker (Walker, 2005). The usage of the word *hacker* has changed over the years. Its etymology has mostly had a creative connotation. However, since the movie *Wargames* in 1983, the general (public) meaning has been to creatively manipulate computer code or procedures to achieve a desired outcome, generally a mischievous or malicious one. For purposes of brevity, the word *hacker* will be used in this chapter not to be imprecise, but more specifically to be consistent with the general connotation of the word.

The rebellious, antiauthority teenager may still exist, but the harm that erstwhile person can do is now less than before, mostly thanks to much higher numbers of installed security software. While it is certainly not ubiquitous, the awareness of computer viruses and worms is higher than what it was, therefore leading to a greater number of protected computers. There are exceptions, of course, but the days are mostly passed when a lone and unassisted teenager can cause significant harm (without a significant response) from his basement computer. However, the problem will never go away. As new, more complex applications are deployed, new exploitable vulnerabilities are found.

Perhaps one of the earliest and best known hackers who had the mind-set, skills, and intelligence for finding vulnerabilities is now out of jail. Having satisfied all penalties levied against him, he now has his own security consulting company and has published more than a few books. According to a recent interview, Kevin Mitnick's original motivation was "fun and entertainment." There was a thrill to gaining access to confidential or proprietary information (Brandon, 2007).

A hacker of more recent fame, the creator of the infamous Samy worm that forced MySpace off line after an XSS attack, created it as a prank according to an interview shortly after the incident. Despite the greater prevalence of security software, the Samy worm raised awareness to the increased risks associated with applications under the Web 2.0 umbrella. When it became known that Samy's very first AJAX project created the Samy worm, business and security leaders took note; if this is his first, what could be next? It may seem a bit perverse that Samy, the perpetrator of the attack, did not fault himself or MySpace for the worm's success, but instead blamed the client browsers for making it easy to run unauthorized JavaScript code on them (Lenssen, 2005).

Like Mitnick who preceded him, but perhaps to a lesser degree, Samy may have gained more than he has lost from his exploit. Although Samy Kamkar was sentenced to probation, community service, and a certain amount of restitution, his reputation has been indelibly etched into Web history. One online news source even referred to his exploit as "cunning" (Orlowski, 2005).

The motivations behind Web 2.0 attacks have changed. While it may have been a prank or an adventure a few years ago, the development of new Web exploits is now the stuff of nationalism, social castes, and real money. A denial-of-service attack that hit Estonia in early 2007 is suspected to be rooted in Russian nationalism, although some security experts dispute the nationalism claim (Brenner, 2007), saying it was motivated by anger over a government decision to move a revered monument. Despite the lingering issue of why the Estonian attack happened, Russia is thought to be a proverbial hotbed of malware (malicious software) engineering (Brenner). Other than the booming petro economy, the Russian "other" economy is bleak, and programmers not only see malware as a money opportunity, they also do not believe developing malware is wrong. Still, the nationalist bent cannot be discounted; a small Russian newspaper reportedly praised the local perpetrators of a hacking attack for their accomplishment at the capitalists' expense (Claburn, 2007). With a report that a Russian Web server was found to be hosting approximately 400 malware applications (Brenner), and a report that China's production of malware exceeds Russia, how long will it be before nationalist Web attacks are directed to the Western hemisphere?

In the West, a social order has developed among the people who develop and/or deploy malware on the Web (Claburn, 2007). Even though Kevin Mitnick has a legitimate career now after paying his dues to society, he is held in reverence and awe by young and aspiring hackers. Samy Kamkar is substantially younger, but his "Samy is my hero" prank on MySpace is still admired by people in their teens, 20s, and even 30s. Even though they are legitimate now because of their admiring fans, both Mitnick and Kamkar are certainly near the high end of the hacker social order.

The lure of an income, perhaps a large income, is a major motivator in both the West and in Asia. No longer is malware just written by and for the exclusive use of its writer. Malware kits, that is, kits for developing malware, are readily available for sale on the Internet. Originators of malware programs or kits are at or near the top of the hacker social order. These are the people who stand to earn the greatest amount of money from their actions, and the money can be considerable. Lower in the hacker social order are the people who buy these kits to develop their own malware, but that does not mean they are of lesser significance; the availability and the use of malware kits are a significant factor in the proliferation of malware on the Internet. Though the road can be tough (Kevin Mitnick was arrested several times), the hope of a lucrative hacking career and the high status it may bring can be compelling.

Malware kits are one source of income. Another money-earning method involves renting botnets. Botnets are networks (or groups) of security-compromised computers known as zombies. Botnets are also used in spamming (mass junk e-mail distributions), focused attacks to steal data, and denial-of-service attacks as client-naïve instruments. They have even been used to extort money under threat of a DoS attack.

Depending on the size of the botnet, that is, how many zombie computers are part of the botnet, the weekly rental income can be several hundred dollars. More income can be earned with the sale of an unpublished security vulnerability, perhaps up to US$1,000 or more (Evers, 2007). What is less known, but feared more, are the markets for identity-related data such as credit card numbers, social security numbers, and company-related confidential information to be used in espionage.

Phishing scams are relatively new, but their impact cannot be understated. With Web sites that look legitimate, but are in fact facades developed to acquire credit card numbers, passwords, social security numbers, and other personal data, phishing is proving to be a lucrative criminal method of cyber attack. Security firms such as Symantec have included phishing protection in their software, and Microsoft has phishing filter functionality included in Internet Explorer 7 to help minimize the dangers phishing can pose to the unwitting user.

WHAT CAN WE DO?

What can be done to mitigate the security risks and minimize the problems that have evolved from Web 2.0? We cannot eliminate the problem of cyber attacks on Web 2.0 applications or otherwise. The best we can hope for is to minimize the probability of an attack, or if attacked, minimize the damage done.

The field is a rapidly changing one, where hackers find a weakness, companies or individuals respond, and society slowly incorporates and adapts to the changes over the long term. During the 1980s, few could have imagined what the Internet in general and Web 2.0 in particular could have become in 2007, but what was unimagined then is reality now: Society will continue to adapt. One constant, though, is that hackers will exploit a weakness, and the rest of us will respond. Society's innovation will always be challenged by the hacker's innovation.

Many blame the rush-to-market mentality of companies in getting their Web 2.0 applications up and running. In their haste to meet deadlines, developers forego what few best practices there are to complete their tasks. There are two things that can be done to address this part of the problem. In 1996, Alan Greenspan, the Federal Reserve chairman, used the term "irrational exuberance" to characterize the overinflated values of the stock market; perhaps companies venturing into Web 2.0 territory need to tamp down their exuberance to a level where their developers can properly include security into their Web 2.0 applications. Secondly, Web security is a rapidly changing field; to keep up with the changes, developers should be continually trained on threats, techniques, and best practices. As mentioned before, there is not one answer to the security problem, but as companies work toward a whole solution, they should concentrate on two of the biggest threat sources: cross-site scripting and cross-site request forgeries.

There is more that companies can do to address Web security issues. Widely acknowledged as a problem, company confidential or proprietary data can appear in Web 2.0 weblogs (blogs) that may eventually become known to the company's competitors. This is not caused by hackers, but more likely company employees, disgruntled or simply naïve. Companies need to develop (better) data policies: Their data need to be identified, managed, and controlled (Vijayan, 2007). Knowing what data the company has and where they are located is an essential first step. Also essential to know is who has access to data; that is, companies should know who should have access and put controls in place to enforce company policy on data.

A more problematic approach is determining if and how to limit employee access to blogs. Whether deliberate or accidental, when an employee puts company data on a blog, they become public and potentially compromise the position of the company. An outright ban on company computers is certainly possible. Web sites can be blocked, firewall rules can be stringently applied, and so forth (Fanning, 2007), but how can a ban be enforced on noncompany computers? The short answer is it cannot, so the likely answer for companies is to take a middle position; develop, apply, and enforce a comprehensive data policy that can extend beyond the company's parking lot.

The onus should not be completely on companies to address Web security problems. Organizations are generally more strident about security, and individuals should learn from their employers and become more security conscious. Personal data should be guarded as closely as company data. Home computers can be current on the latest security software just as work computers are (usually). Individuals should recognize the public nature of the Internet and the Web, and realize that *public* does not mean *safe*. Web 2.0 has enabled the Web to become more of a conversation than a billboard; that conversation will have questionable and nefarious participants, and individuals have to remember that.

WHAT IS ON THE HORIZON FOR WEB SECURITY?

As suggested in the previous section, companies and individuals are reacting to the Web security issues that have been exacerbated with Web 2.0 technologies. Some believe there really is one magic solution, while others embrace the idea that a comprehensive strategy and solution is the best approach.

One notable and positive trend is the telltale movement to thin-client applications and hardware. Thin clients are essentially input and output devices only; the applications, heavy processing, and data reside on a server. With the advent of fast corporate and broadband networks, thin-client computing is more possible than ever. In 1995, Oracle founder Larry Ellison presaged a future where network computers replaced the personal computer (Bock, 2006). Though his reasoning was based on the growing complexity of personal computers during the 1990s and not the security concerns raised in the 2000s, his prediction was nevertheless prophetic. Microsoft now has in beta a server-based version of Office that will further the trend of thin-client applications. With computing power and data moving to more protected Web servers, opportunities for intrusion are lessened and malware attacks will be reduced.

The best practices for Web security are developing and becoming better known. When Web 2.0 applications began to appear, the best practices had not caught up to the technology, but that is changing now. Control Objectives for Information and Related Technology (COBIT) is both a format and forum for governance of all things IT. As practices become established and accepted by the IT community, COBIT-codified practices are updated and disseminated through traditional channels such as conferences and published standards. Web 2.0, podcasts, blogs, and wikis, though perhaps nontraditional channels now, are becoming evermore important in communicating best practices to the people and organizations that need them.

There may be a developing trend with negative consequences for Web security, at least in the short term. An increasing number of acquisitions of Web security specialty firms have some security experts concerned. With IBM's acquisition of Watchfire and HP's recent acquisition of SPI Dynamics, will the products of those companies be less available to the general market? These smaller companies, before their acquisitions, were autonomous leaders in Web 2.0 security. However, with their independence gone, it is unclear whether their products will be directly available to the market at large, or limited as offerings from the acquiring companies. This should be a short-term problem because their technology, and technology from other similarly acquired companies, will eventually make its way to the market (Germain, 2007).

CONCLUSION

Where are we now with Web security? This chapter has examined the background and evolution of where we were. It is evident now that with the advent of Web 2.0, the security technology for Web applications lagged behind the technology for the social software embodied in Web 2.0.

This gap in technologies created an opportunity for makers of mischief, maliciousness, espionage, and profit. However, the market has responded and will continue to respond.

In the context of Web security, terms such as AJAX and SOAP may never become well-known outside IT circles, however the impact they have (and will) have on all of us cannot be understated.

This is certainly not to suggest or imply support of hackers, their social order, or the nationalistic motivations behind Web security incursions and attacks, but what is the underlying net effect of hackers, nationalists, IT, and security companies? Is the net effect positive, negative, or neutral? Besides the obvious inconveniences and annoyances, the negative side includes companies sabotaged, extorted, and coerced out of uncounted sums of money. IT departments have had to divert resources to the security problem in order to plug the leaks known and identify the holes not yet known, and individuals have had identities stolen and bank accounts drained.

Is there a plus side? Perhaps yes—more companies have been created that specialize in Web security, IT department budgets have been increased to augment their security staffs and tools, and while of questionable value, some (formerly unemployed) people in Asia and elsewhere are now working to help meet the burgeoning demand for malware.

From a dispassionate viewpoint, one might argue that the plusses outweigh the minuses; that is, the response to Web security problems has been more beneficial to the many than harmful to the few. A victim of identify theft or the CEO of a company that was impacted by an attack or extortion will surely disagree.

It should be clear that there will always be concerns over Web security. A certain trend is that knowledge of the security threats arising from Web 2.0 is spreading, and users, developers, and companies are responding with education, new products, and new strategies to mitigate the risks.

In this Web 2.0 world of podcasts, blogs, and wikis, there is an unfortunate but real repeating process that helps keep IT security managers employed. As security awareness increases, knowledge increases; as knowledge increases, the potential for new security threats increases. Although security is fleeting, the field of IT security is forever.

Chapter 1.15
Web Site Localization Practices:
Some Insights into the Localization Industry

Nitish Singh

Joseph P. Little
Saint Louis University, USA

ABSTRACT

The e-commerce industry has experienced spectacular growth, change and development. This situation has initiated an enormous business revolution that has affected the process of globalization tremendously. The goal of this study was to analyze the Web sites of localization companies that provide localization and translation services to other companies and see if they themselves are practicing what they are preaching. The results suggest that localization companies are indeed not practicing what they are preaching. Analysis shows that localization company Web sites are less localized than the Web sites of their clients, the multinational companies. The findings provide some implications to domestic and international marketers who currently operate in or are planning to enter into the global markets in the near future. [Article copies are available for purchase from InfoSci-on-Demand.com]

INTRODUCTION

From the mid-1990s to the present day, the e-commerce industry has experienced spectacular growth, change and development. The global online population is estimated to reach 1.8 billion by 2012 (Jupiter Research, 2008). In 2008 North America accounted for only 17.5% of the online population and that percentage is in decline as countries such as China, Brazil, India, and Russia show the highest level of online population growth (Internet World Stats, 2008). This situation has initiated an enormous business revolution that has affected the process of globalization tremendously (Cyr & Lew, 2003). During the past several years an entire industry (the localization industry) has grown up around helping companies design multilingual Web sites and software applications for different countries. An industry report estimates the size of the worldwide translation and localization services market at US$ 8.8 billion (DePalma & Beninatto, 2006). According to this report the commercial market for localization services is estimated at US$6 billion and the government market at US$ 2.8 billion worldwide.

Localization is the process of adapting products and services (Web sites, manuals and software) in accordance to linguistic, cultural, technical and other locale-specific requirements of the target market (Localization Program at California State University, Chico, College of Business, 2008). Localization is now being seen by multinationals as a necessary process to develop multilingual and multicultural content to effectively tap global markets. Forester research estimates put the 2006 global e-commerce revenues at around $12.6 trillion. Furthermore, research has shown that consumers prefer Web sites in their native language and Web sites that reflect their local preferences (Singh, Furrer, & Ostinelli, 2004). Thus, companies around the world are creating multilingual Web sites to tap this vibrant online market. Companies like IBM, Oracle, Intel and other have almost 90 international sites to take advantage of the global online markets and communicate with their global customers. This surge in creating multilingual online content and software has also led to the growth of the localization industry which is helping these companies by effectively translating their Web sites, user interfaces, software, and manuals. Beyond translation the localization companies are also involved in the following (Esselink, 2000):

- Making visual or graphics, technical and textual modifications to the site content.
- Rewriting the text, translating the text, and ensuring translation, idiomatic, and conceptual equivalence of the translated text.
- Modifying graphics, data fields, tables, forms, layout, colors and tables etc.
- Modifying the cultural content of the site or software to be congruent to the local culture.
- International e-commerce readiness for multi-country transactions.
- Web site navigational modifications to meet local preferences.

This study analyzes the Web sites of localization service providers in order to understand to what extent these companies are translating and localizing their own sites, and modifying graphics, layout, colors, text, policies, navigation, and cultural content. The study then compares the localization efforts of the localization vendor company with their clients, who are generally multinational companies. This analysis will reveal if the companies that are preaching localization are also effectively implementing it on their own Web sites. After all, the localization service providers should set the benchmarks for their clients to follow. Moreover, the companies that will be the winners in this fast growing and consolidating localization industry will be the ones that are able to highlight and exemplify the need for Web site localization. What is a localization service provider telling their current clients along with potential future clients if their own Web sites are not sufficiently localized? The goal of this article is to gain understanding of the localization processes used in the localization industry and to focus on the current trends in the localization industry.

This article is composed of seven sections. The first section presents and introduces a review of the globalization and localization literature. Section two explains the research methodology. Section three provides a presentation of the analysis. Section four provides a discussion of the results, section five describes some managerial implications, section six explains some limitations along with future research ideas, and finally section seven provides a conclusion.

LITERATURE REVIEW

Globalization and the Localization Industry

Increased ownership of computers and Internet usage is growing every day. Throughout the world the Internet is rapidly becoming the main source for information, shopping and services. Furthermore, computer and Internet users are increasingly from non-English speaking countries. One estimate indicates that 32% of Internet users are non-native English speakers. This number is increasing. The result of this huge Internet expansion motivated businesses to recognize the value of Website localization (Kwintessential, 2009). Moreover, the unending process of globalization is fundamentally altering the manner in which enterprises do business. When businesses globalize their e-business, there is a great need recognize that language, cultural expectations and trust play a huge role when building online Web capabilities (Culnan & Armstrong, 1999; Jarvenpaa, Tractinsky, & Vitale, 2000; Singh & Pereira, 2005; Violino, 2001). For an organization to be successful in this demanding setting, they must adjust their offerings so that their products and services present the appearance and feel of being produced locally. The process of localization begins with an understanding of a wide range of linguistic, cultural, content, and technical issues. A product or service presentation has to be tailored to the local customs and practices of a country or region. For example, producing a Web site in only the English language is not sufficient because the majority of the world does not understand English. Furthermore, even if consumers do understand English research has shown that they prefer Web sites in their native language (Singh et al., 2004). While many companies use machine translations to adapt the language used on their Web sites (Singh & Boughton, 2002), this type of translation is not sufficient either. Languages not only differ in their use of characters or syntax, but also their use of rhetorical style and use of metaphors. Therefore, a simple machine translation, without an understanding of a culture and its language, may result in a cultural faux pas (Singh et al., 2004). Beyond linguistics companies also need to consider such culturally sensitive areas such as persuasion techniques, colors, icons, signs, Web page layout, and cultural values when localizing Web sites (Singh & Pereira, 2005).

Previous research has shown that culturally sensitive Web content enhances the site's usability (Fock, 2000; Luna, Peracchio, & de Juan, 2002; Singh & Pereira, 2005; Simon, 2001). So, in order to effectively communicate to foreign online consumers it is beneficial for a firm to adapt their Web sites to the targeted market. Furthermore, research has shown that not only does Web site localization enhance usability but also attitude towards the Web site, perception of the ease of site navigation, and ultimately purchase intention (Singh et al., 2004).

The cultural impact is substantial and Hall (1976) believes that it is very difficult to act or interact in any meaningful way if they do not understand language and culture. The consequence of not including language and culture, when considering global Web presence, is discarding profitable global online consumer. The Internet, similar to any other advertising document, is a replica of the culture of the country or locale (Cyr & Trevor-Smith, 2004; Hermeking, 2005; Singh & Matsuo, 2004). According to Mooij (1998) advertising mimics a society's values. It can only be effective when it is inseparably connected to the primary culture of the group for which it is targeted. Studies have demonstrated that advertising that is harmonious with local cultural values is significantly more compelling than standardized advertising. Several researchers, therefore, have emphasized the use of country-specific cultural values appeal when developing international advertising campaigns and communication material (Albers-Miller & Gelb, 1996; Han & Shavitt, 1994). Research indicates that Web site localization and cultural customization promotes a better opinion regarding the site ultimately influencing people's purchase intentions (Singh & Pereira, 2005). Luna et al. (2002) discovered that culturally harmonious Web content creates a more user friendly environment where the user has clear instructions and comes away from the Website with a better attitude about the content that is presented. Consequently, the localization of Web sites also necessitates culturally tailoring the Web sites to be congruent with the cultural requirements of the local environment. Miscommunications, in the international context, generally take place when the message is seemingly mismatched with the local culture and does not produce the response that was expected towards the businesses products or services. The foreign language, signs and symbols, and Web content that is culturally different, creates confusion, frustration, offensiveness and in the long run a loss of business (Luna et al., 2002).

While company Web sites provide a major opportunity to impart and promote a corporate image and to sell products and services, the effectiveness of the Website depends almost exclusively on the value of its content (Pollach, 2005). An effective Web site is the one where the consumers invest a considerable amount of time reviewing the content of interest, requesting more information, and buying the goods or services offered (Liu, Marchewka, & Ku, 2004). As such, the quality and value of a Web site will be influenced by how the Web site mirrors the culture of the nation for which it has been designed (Fletcher, 2006; Singh & Pereira, 2005).

Culture influences just about everything we do, say, read, hear and think. Web sites are not immune to the affect of culture (Kwintessential, 2009). Those companies that are able to develop, manage and customize their business Web sites to the culture of the country they are doing business, will generate more interest in their company and ultimately increase the sales of their products and services.

The differences in cultures require international businesses to find ways to make their Web sites communicate with different cultures in different parts of the world. As such, the key acronym that has emerged in this new arena of business operation is GILT or Globalization, Internationalization, Localization and Translation (Lommel, 2003). Globalization addresses the enterprise issues associated with making a company truly global. So, for products and services this means integrating the internal and external business functions with marketing, sales, and customer support in the world market (The Localization Industry Standards Association, 2008). More specifically, Web site globalization includes two complementary processes: Internationalization and Localization.

Internationalization is the process of generalizing a product so that it can handle multiple languages and cultural conventions without the need for redesign. In more technical terms, it is the process through which back-end technologies are used to create modular, extendible, and accessible global Web site templates that support front-end customization (Singh & Boughton, 2005). This process enables company Web sites to be locally responsive to the end-user through front-end customization. Internationalization takes place at the level of program design and Web document development (Singh & Little, 2009).

Localization and translation is the process of adjusting a product or service and making it linguistically and culturally appropriate to the target locale. More specific to the current study, Web site localization is the process of the front-end customization, whereby Web sites are adapted to meet the needs of an international target market (Singh & Boughton, 2005; Singh & Little, 2009).

The localization industry can trace back its roots to early 1980's when the software industry was emerging as an upcoming sector of the US economy, and felt a need to translate software products in multiple languages (Globalization

Industry Primer (LISA), 2007). As the application of software grew across a cross-section of industries and with the growth of the Internet, the localization industry also saw sustained growth. Now the localization industry is seeing a growth phase with the need for translation and localization of software, manuals, packaging, and most importantly multilingual Web sites. The industry is also undergoing considerable consolidation. During the 1990's the trend toward industry consolidation started with small vendors joining hands to offer "one-stop shopping" for large software developers like Microsoft, Oracle, and IBM who needed translation and localization services in multiple languages (Cyr & Lew, 2003). The industry consolidation leads to the emergence of multi-language vendors (MLVs) which specialized in completing multi-language, multi-service localization/translation projects. These MLVs also used an outsourcing model where they outsourced the core translation services to single-language vendors (SLVs); Single Language Vendors normally work into one target language only, from one or more source languages (Esselink, 2000). The acquisition of Bowne Global Solutions by Lionbridge Technologies in 2005 lead to the emergence of Lionbridge as one of the largest Globalization and off-shoring companies in the industry. Similarly, SDL International, another major player in the localization industry, enhanced its portfolio by acquiring Trados Inc., which was a major translation technology solution provider. As the localization industry grows, and serves new and bigger clients across a cross-section of industries, it will need localization vendor companies to invest in process and product innovations and R&D to be competitive. In order for these large investments and comprehensive solutions to be provided, vendors will need to be backed by substantial capital investments. However, Leon Z. Lee (2005), an industry expert, warns that the current focus of large and small localization companies toward primarily cost leadership, automated enterprise workflows, and technology integration from corporate consolidations is not a recipe for long term growth and sustainability of this industry. Lee (2005) recommends that for the localization industry to be viable it needs to expand its role from just a translation or technology-solution provider to truly embracing the wider concept of localization by providing international marketing expertise. This international marketing orientation will then help the localization companies to expand their offerings by delivering localized information and comprehensive resident knowledge in designing marketing campaigns for geopolitical and ethnographic regions in areas of print advertisement, online brand valuation, and Website usability analysis (Lee, 2005).

The next sections of this article will detail the methodology, sample, and the analyses used in this study. Additionally, insights into the current level of localization practiced by localization vendors and their multinational clients are presented.

METHODOLOGY

To analyze the quality and extent of localization depicted on the localization vendor Web sites, the study conducted a content analysis of the vendor Web sites and Web sites of multinational companies. More specifically, content analysis methodology was used and a coding system was developed to measure various facets of the localization efforts. The coding system used in this study was adapted from Singh, Toy and Wright (2009). The coding sheet included items like:

- Ease of finding global gateway on the Web site
- Use of country code domain names of ccTLD
- Translation depth
- Local customer support
- E-commerce information and policies
- Navigational outlay

- Web site page structure/layout
- Use of Locale-specific graphics, colors and values.

To perform the content analysis two coders were trained in the coding scheme and jointly coded several Web sites. The inter-coder reliability on the sample of vendor and multinational client Web sites ranged from .82 to .86. It is suggested that inter-coder reliability needs to be above .80 in order to be acceptable (Grant & Davis, 1997). Thus, the coder reliability exceeded the suggested threshold.

SAMPLE

Analyzing all country sites (which can range from 10-90 and may include more than 2000 pages) to measure localization efforts was beyond the scope of this study. Thus, the study measured the localization efforts on the German and Spanish Web sites of each vendor company. German and Spanish have been forecasted as some of the top languages in which multinationals are localizing their sites.

To find a sample of localization vendor company Web sites the study used the vendor company data base provided at the Globalization and Localization Association Web site. In total the study was able to include only 53 localization vendor company Web sites in the sample, as these were the only companies we found having international Web sites for Germany and Spain. Thus, 53 companies and their German and Spanish sites served as the final sample, which included almost 106 Web sites and more than a thousand Web pages. The study also analyzed the company home site (mostly in English) to see the structure of the global gateway, Web page structure, and Web content depth and navigation. The sample of multinational company Web sites was selected from Forbes top 500 international company list. 100 multinationals were identified that had international Web sites and Web sites specifically for both Germany and Spain. Thus, a total of 100 multinationals with 300 country sites (U.S. English, Germany and Spain) were analyzed for this study.

RESULTS AND ANALYSIS

Number Unique Languages Supported

The purpose of finding the number of unique languages was to understand how many languages is the company providing its services in. The results show that on average a vendor company site had about 7 unique languages depicted. On the other hand the Vendor clients, such as Multinational company Web sites had on average 19 unique languages supported. This shows that Localization vendors are far behind their clients in terms of languages supported on the site (see Table 1). In fact the mean number of languages depicted by multinational Web sites (19.38) exceeded the maximum depicted (16) by the vendor sites. An independent sample t-test indicates the means are significantly different ($F = 37.708, p = .000$).

Ease of Finding Global Gateway

The aim here is measure how visible the link for international sites is from the company's U.S. English home page. Based on the comparison data between the vendor and client Web site, it seems 30 percent of client (Multinational) sites have a dedicated global gateway page compared to which only about 9 percent of vendor sites have a dedicated gateway page (see Table 2). The results of a chi-square test for two independent samples indicates there is a significant difference in the presentation of a global gateway page between vendor and multinational sites ($\chi^2 = 22.191$, $p = .000$). However, it seems both vendor and client sites are lacking quality gateway pages, which

Table 1. Number of languages used

Number of Languages Used

	N	Minimum	Maximum	Mean	Std. Dev.
Vendor No. of Languages	53	3	16	7.11	3.06
Multinational No. Of Languages	102	5	38	19.38	7.44

Table 2. Web site global gateway page

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
No Link	0	7	0	6.80
Not Easy to Locate	6	20	11.32	19.42
Located at Middle Third	18	12	33.96	11.65
Located at Upper Right Corner	24	33	45.28	32.04
A Dedicated Global Gateway Page	5	31	9.43	30.10
Total	53	103	100.00	100.00

are crucial to drive international online traffic to country-specific sites.

Use of Country-Specific Domain

The goal here is to see if the company has invested in buying the country code top level domains also called cctld for the country. The use of ccTLD helps in international search engine optimization and also shows commitment of the company to that country market (see Table 3). The analysis shows that no vendor site was using ccTLD exclusively to create international sites. Most vendors were using some extension of .com/Spain of .com/Germany. The client multinational Web sites did relatively better in terms of use of ccTLD. About 26 percent of multinational sites were fully using ccTLD for their international Web sites. The results of a chi-square test for two independent samples indicates there is a significant difference in the use of ccTLD between vendor and multinational sites ($\chi^2 = 20.346$, $p = .000$).

Localization Assessment of Country-Specific Web Sites (Germany and Spain)

- Translation Depth: Translation depth was measured to see to what extent are the companies translating their Web pages relative to U.S. English Web pages. To measure translation depth the study counted the number of English page and local language primary links or main links on the home page of English and local language site. The results, in table 4, show that on vendor Web sites about 85 percent of English pages links were translated. On the other hand in terms of Multinational sites, on average about 67 percent of English page links were translated.
- Content Localization: This Category measures to what extent the company has localized its Web site content in terms of local

Table 3. Web site use of country-specific domain

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
No ccTLD	22	20	42.31	19.80
Not Fully Using ccTLD	30	54	57.69	53.47
ccTLD Used	0	27	0.00	26.73
Total	52	101	100.00	100.00

Table 4. Web site English vs local language links

	N	Minimum	Maximum	Mean	Std. Dev.
Vendor - English	53	5	92	28.51	20.04
Multinational - English	101	4	299	56.08	47.10
Vendor - Local Language	102	2	96	24.23	19.01
Multinational - Local Language	202	3	177	39.73	30.55

support, e-commerce related information, and navigational ease.

- Local Customer Support and Contact: By analyzing the level of local customer support it can be measured to what extent is the company localizing its customer service efforts for a specific-locale (see Table 5). The results show that while both the vendors and the client multinationals are not fully localizing their sites, the vendor sites depict far less degree of localization efforts. Only about 4 percent of vendor sites had local support pages which were equivalent to their US Web site, compared to 24 percent by multinationals. The results of a chi-square test for two independent samples indicates there is a significant difference in the use of local customer support between vendor and multinational sites ($\chi^2 = 21.200$, p = .000).
- Availability of all policies and e-commerce information such as shipping policy, return, privacy, terms of use, copyright etc.

Table 5. Web site level of customer support

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
No Online Support	6	14	5.94	6.93
Basic Support	15	20	14.85	9.90
Basic Support - Customer Contact	38	68	37.62	33.66
Several Pages of Support	38	51	37.62	25.25
Equivalent to English Site	4	49	3.96	24.26
Total	101	202	100.00	100.00

Table 6. Web site e-commerce and information use policies

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
Not Available	70	26	69.31	12.87
Only One or Two of the Policies	2	30	1.98	14.85
2-3 Policies Available	3	18	2.97	8.91
Most Policies Available	4	32	3.96	15.84
All Policies Available	22	96	21.78	47.52
Total	101	202	100.00	100.00

Table 7. Web site navigational ease

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
Very Poor	6	7	5.94	3.47
Poor	24	27	23.76	13.37
Few Navigational Elements	35	54	34.65	26.73
Navigational Elements Seen	28	61	27.72	30.20
Navigation Elements Equivalent to English Site	8	53	7.92	26.24
Total	101	202	100.00	100.00

Under this category the results for vendor and client sides were very different. Almost 70 percent of vendor sites did not have policies related to e-commerce and information use (see Table 6). This shows that most vendors are not very global in terms of conducting e-commerce. On the other hand, almost 47 percent of multinational sites had all the policies available. These results suggest that at least half the multinationals are localizing their site in terms of e-commerce readiness. The results of a chi-square test for two independent samples indicates there is a significant difference in the availability of policies between vendor and multinational sites (χ^2 = 101.136, *p* = *.000*).

- Navigational ease in terms of sitemap, local search, navigation buttons etc (see Table 7): Analysis of navigation revealed that only about 8 percent of local vendor sites had navigational elements that were equivalent to their US home pages. On the other hand the 26 percent of the multinational client site had navigational elements equivalent to the US English pages. In general, both Vendor and Client Web sites were not highly localized in terms of navigation. However, the results of a chi-square test for two independent samples indicates there is a significant difference in the navigational ease between vendor and multinational sites (χ^2 = 18.085, *p* <= *.001*).
- Layout and cultural adaptation
  - Web Page Structure (see Table 8): The Overall Look of the Site and Design: Under this category the objective is to measure to what extent the look and the layout of the Web site has been localized for a specific-locale. Surprisingly, almost 92 percent of vendor international sites for Spain and Germany were basically standardized templates of their US site.

Table 8. Web site page structure

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
Standardized	96	92	92.31	45.10
Mostly Standardized	5	27	4.81	13.24
Some Differences	3	37	2.88	18.14
Localized	0	28	0.00	13.73
Highly Localized	0	20	0.00	9.80
Total	104	204	100.00	100.00

Table 9. Web site local culture

	Vendor Frequency	Multinational Frequency	Vendor %	Multinational %
Standardized	97	72	93.27	35.29
Mostly Standardized	4	52	3.85	25.49
Some Differences	1	38	0.96	18.63
Localized	0	34	0.00	16.67
Highly Localized	2	8	1.92	3.92
Total	104	204	100.00	100.00

Multinational sites also did not seem to achieve much localization under this category with almost 45 percent international sites being standardized. The results of a chi-square test for two independent samples indicates there is a significant difference in the structure of the Web pages between vendor and multinational sites (χ^2 = 66.671, *p* = *.000*) **(see** Table 9).

- Use of local models, graphics, colors and other cultural markers.Under this category the study measures if the site uses local models, different colors more appropriate for the country, and cultural symbols. The results show that only about 2 percent of vendor sites are localized or highly localized, compared to 20 percent of multinational sites. It seems neither vendors or multinational clients are truly focusing their efforts to culturally customize their sites, even though a growing body of evidence is suggesting that cultural customization of sites leads to better attitude and intentions to buy online (Singh & Pereira, 2005). The results of a chi-square test for two independent samples indicates there is a significant difference in the use of local culture between vendor and multinational sites (χ^2 = 95.101, *p* = *.000*).

DISCUSSION

The results clearly show that companies (localization vendors and multinationals) are currently not fully localizing their sites in terms of using country code top level domains, global gateway pages, customer support, e-commerce and information use policies, navigation, Web site structure, layout, colors, and graphics. It is even more concerning that companies selling localization services are actually localizing their own sites to a much lesser extent than multinational companies, the firms that tend to be their clients. The localization industry is not practicing what they preach.

In every single category examined in this study the multinational Web sites were shown to be more localized than the vendor Web sites. A telling comparison is the number of distinct languages used. Vendor sites average using seven different languages compared to multi national sites that average nineteen different languages. This result exemplifies the lack of localization practices being used by the vendors themselves. Furthermore, over 93 percent of vendor sites are culturally standardized.

None of the vendor sites were found to be using a ccTLD which is surprising as international domains are crucial for international search engine optimization. This may be due to the fragmented nature of the localization industry wherein small localization vendors from a specific country tend to serve their own local market and are content with their local customer base. However, large localization vendor Web sites also seemed to show lack of ccTLD use and an overall low level of localization on various parameters we used in this study. So, do these vendors really believe that Web site localization practices are important? From this study's results, the picture we get is that vendor sites are lacking commitment toward localization. However, before reaching any conclusion we should consider a bigger picture and understand what are the reasons for localization vendors to not sufficiently localize their sites? In the limitations and future research section we discuss some of these issues.

MANAGERIAL IMPLICATIONS

With few large localization vendors like Lionbridge Technologies, SDL International, and Translations.com holding the top positions there seems to be a large segment of niche markets that small localization vendors or single language vendors are able to serve without much competition. However, as the localization industry consolidates and matures, it will be difficult for small localization vendors to remain competitive and profitable by just providing generic translation/localization services to niche markets or local country markets. Even large sized localization vendors risk losing their competitive position due to industry consolidation, over-reliance on generic translation services, and cut throat price-based competition. If the localization industry wants to keep its competitive position and provide a healthy industry environment for both small and large localization vendors to grow, it must go beyond generic product offerings in the form of translation services, and expand the definition of localization to include not just translation but to also offer:

- Localization of the Website lay out and navigation based on locale-specific requirements.
- Cross-cultural Web site and user interface usability research.
- Country-market analysis
- Cultural customization of Web sites to specific locales
- International online business strategy and marketing expertise
- Online branding and advertising localization
- International search engine optimization and search engine marketing

These are just some ways the industry can expand the definition of localization and offer complementary services that can help companies differentiate their offerings from their competitors and stay profitable.

Localization services firms, in order to be profitable in the future, must practice what they preach. They must practice not only to exemplify their services being sold, but also to appeal to an international market. Research has shown that individuals prefer Web sites that are localized to their own language and culture (Singh et al., 2004).

LIMITATIONS AND FUTURE RESEARCH

The current study is an exploratory study focusing on the amount of Web site localization used by vendors offering Web site localization services compared to their clients level of Web site localization (multinational company Web sites). So, the data analysis here is a simple frequency examination. The goal of this study was to examine the use of localization practices frequency and that goal was met. However, further, more in-depth data analysis could be used in the future. Another limitation to this study was the sample used. The vendor Web sites may not be intended for an international audience. As stated earlier, many of the smaller localization firms are serving single, niche markets. On the other hand, multinational company Web sites, by their nature, are meant for international consumption. Therefore, it is expected that vendor sites may be less localized than their client's sites. However, the results show that even the large localization services firms lack localized content on their Web sites to meet the needs of an international market. Furthermore, even the smaller firms should aspire to exemplify the practices that they preach.

Future research directions should include a closer examination of localization practices within the localization industry. A comparison between the large localization service firms Web sites and their smaller, niche market, counterparts is needed. Also, a longitudinal study examining the increased amount of localization used on the internet is warranted. Is the trend to localize Web sites to a greater extent, or are more Websites trying to serve a smaller, local niche market instead of an international market? If the trend is to serve international markets then are the localization practices keeping up with international expansion?

To further shed light into why localization vendors are not actively localizing their sites we need further research to investigate their overall globalization strategy by asking questions such as:

- Are the localization vendors just targeting some large multinational companies from predominantly English speaking countries (U.S., U.K., Australia etc.) and a few other non-English speaking countries?
- What resource and marketing constraints do these vendor companies face?
- Another interesting question to investigate is to understand the top management willingness to globalization and their vision for globalization. It seems several small and medium sized localization companies are run by top management which has primarily a translation background. So is it the lack of business education background that is restricting the global expansion of localization vendors?

Thus, to get a full picture of Web globalization efforts of localization vendors, we should not lonely study localization vendors Web sites but also understand their overall globalization strategy and how it has evolved over time.

CONCLUSION

The findings of this research suggest that both localization vendor and multinationals are barely localizing their Web site offerings. This may not be all bad news, as more multinationals seek to tap online markets and compete for them, the winner will be the multinational sites that are truly localized and speak to their international customers in their language and culture. Localization service sales may be increased by simply practicing what they preach.

Not only has research shown that consumers prefer localized Web site content, but research has also shown that by localizing you can increase traffic to Web sites (Ferranti, 1999), and increase willingness to purchase (Singh et al., 2004). Localization services vendors may be missing out on increased sales by simply preaching and not practicing. Actually, applying what they preach to their own Web sites, according to research, should increase the amount of traffic to their sites while also increasing the willingness to purchase their localization services. This means that the localization industry can look forward to significant growth, but only if it can educate its multinational clients about the importance of localization and the best way to do that is to practice what they preach.

ACKNOWLEDGMENT

The data collection for this study was supported by students and Gary Muddyman, CEO of Conversis Global.

Section II
Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of Web technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on particular frameworks and infrastructures, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful Web sites, Web-based applications, and Web portals are provided.

Chapter 2.1
Perceptions of Mobile Device Website Design:
Culture, Gender and Age Comparisons

Dianne Cyr
Simon Fraser University, Canada

Milena Head
McMaster University, Canada

Alex Ivanov
Simon Fraser University, Canada

ABSTRACT

Anytime anywhere services offered through mobile commerce hold great potential to serve customers in wireless environments. However, there is limited understanding of how mobile Web site design is perceived by diverse users. This chapter explores how users who differ by culture, age, and gender perceive the design of a mobile device and their subsequent level of satisfaction with the device. Sixty subjects were tested in a controlled laboratory experiment on an Internet enabled phone. The results of a quantitative analysis were statistically inconclusive in terms of cultural and gender differences, but significant differences were found between older and younger users. However, an in-depth qualitative analysis of interview transcripts revealed some interesting differences among cultural, gender and age groups. Consistent with findings in the stationary Internet domain, design elements were found to impact satisfaction with mobile services.

DOI: 10.4018/978-1-60566-366-1.ch010

INTRODUCTION

Organisations will be well served to not be complacent with their wireless site design efforts… [But] before wireless site designers can address the usability challenge, and before organisations can leverage the commercial benefits of m-commerce, a deeper understanding of what aspects of usability is important to users and how they may differ in a wireless context is required. (Venkatesh et al., 2003, p.56)

Mobile commerce[1] (or m-commerce) has huge potential to serve customers in wireless environments. The adoption of m-commerce is dependent on consumer acceptance of new and well-designed technologies (Ancker & D'Incau, 2002; Coursaris et al., 2003: Kim et al., 2002; Kumar & Zahn 2003; Nysveen et al., 2005; Perry et al., 2001; Schrott & Gluckler, 2004; Yang, 2005). It is expected design characteristics may influence user perceptions towards a mobile device. Congruent with work done by Cyr (2008), Information Design (ID), Navigation Design (ND), and Visual Design (VD) may all contribute to user adoption of a technology, as well as to satisfaction with a mobile technology.

Concerning user attitudes of handheld devices, it is also expected that diverse categories of users based on culture, gender, or age may react differently to using the device. There is growing literature on cross-cultural website design, mostly evaluated within the context of the stationary Internet (Becker, 2002; Chau et al., 2000; Cyr, 2008; Cyr et al., 2006; Cyr & Trevor-Smith, 2004; Marcus & Gould, 2000; Sun, 2001). More recently, research has examined culture and mobile data services (Choi et al., 2006). Investigations have likewise examined gender and design in the context of mobile devices, but research results are mixed (Anckar & D'Incau, 2002: Kwon & Chidambaram, 2000; Teo et al., 1999). Finally, research that examines cohorts by age (younger versus older users) is practically nonexistent when design is considered, although some studies have focused on special needs and preferences of older users (Goodman et al., 2005), or features of a mobile device perceived by user groups as adding value (Anckar & D'Incau 2002).

To explore the role of user differences concerning the perception of the design of a mobile device, users who differ on cultural, gender and age dimensions were tested on an Internet enabled cellular phone. Related to culture, Canadian and Chinese cultures were chosen due to acknowledged diversity (Hofstede, 1980). Between-group comparisons were conducted with respect to screen design (including information design, navigation design, and visual design), and satisfaction with the mobile device. In an exploration of these topics, the paper provides a review of relevant literature leading to the hypotheses for testing, the methodology used, an elaboration of results, and discussion of the findings. Given the increased diversity of mobile users, developing an expanded understanding of user perceptions and preferences not only has theoretical importance, but also serves to enhance the reengineering of devices to best meet consumer requirements.

MOBILITY AND DESIGN

In the realm of the stationary Internet, effective website design engages and attracts online consumers (Agarwal & Venkatesh, 2002; Fogg & Tzeng, 1999; Hui & Triandis, 1985; Morgan & Hunt, 1994; Schultz, 2003). According to Gommans et al. (2001), 'A website has to be designed for a targeted customer segment…' Chau et al. (2000) argue the modes of information presented on the Internet, and the quality of graphics has a significant impact on user experience. Research in design suggests various guidelines for effective Web navigation (Childers et al., 2001; Farkas &

Farkas, 2000), criteria for optimal Web design (Bernard, 2002; Egger 2001), and how aesthetics and usability might be linked (Tractinsky, 1997). The sensory experience of the website can help to determine if a user stays and shops at a site (Rosen & Purinton, 2004; Yoon, 2002).

The quality of handheld displays that favor enhanced information design and visual design is steadily increasing and affects user perceived effectiveness of the presentation (Rau et al., 2006). While mobile screens are much smaller than those available on the stationary Internet (Schmidt & Frick, 2000), various studies demonstrate comprehension rates on smaller screens are generally equivalent to their larger counterparts (Dillon & McKnight, 1990; Duchnicky & Kolers, 1983; Resiel & Shneiderman, 1987). Other researchers consider the smaller screens of mobile devices a 'serious obstacle to usability of the mobile Internet' (Chae & Kim, 2004, p. 165). Sarker & Wells (2003) examined interface characteristics and network capabilities that affect the implementation and acceptance of wireless phones. They discovered while users were 'quite forgiving of physical limitations of the device due to technological constraints, they were bothered by flaws in the interface of the devices' (p. 37).

In recent years there has been increased attention to mobile usage and in 2004 the *International Journal of Human-Computer Studies* devoted a special issue to this topic. The issue addressed mobile use in a variety of contexts including human characteristics and interface systems, although design aspects of the mobile website were not specifically considered. Further, in 2005 *Behaviour & Information Technology* devoted a special issue to mobility from a human computer interaction (HCI) perspective. Topics included navigation support, user acceptance and trust, and user evaluation of usability of mobile devices. In research in which interface design and usability are examined for wireless devices in m-commerce, Tarasewich (2003) suggests many current principles of interface design can be transferred to mobile devices. He examines various issues such as content, user interaction with the device, issues of reading text on small screens, rapid serial visual presentation, and browser types.

Relevant to the current research, design categories for information design, navigation design, and visual design as suggested by Garrett (2003) were selected for systematic examination. A definition of each category follows.

a. **Information design:** Elements of the site that convey accurate or inaccurate information to a user. For instance, the location of an icon on the screen would be the domain of information architecture, but whether or not that icon conveys the right information to a user is the domain of information design. Clear and logical presentation of information about services or products is also a component of information design.
b. **Navigation design:** The navigational scheme used to help or hinder users as they access different sections of the site, such as the location and format of navigation aids.
c. **Visual Design:** Elements that deal with the balance, emotional appeal, aesthetics, and uniformity of the website overall graphical look. This includes colors, photographs, shapes, or font type.

These categories are represented in other work in design (Agarwal & Venkatesh, 2002; Yoon, 2002; Flavian et al., 2005; Palmer, 2002; Simon, 2001), and while not exhaustive are representative of key elements of website usability. The same categories were used by Cyr (2008) to study website design across cultures, and by Cyr and Bonanni (2005) regarding website design and gender. Further, in a study of mobile services Choi et al. (2006) consider three categories of user experience across cultures. These are content (similar to information design), information architecture (which includes navigation design), and graphical user interface (which is similar to visual design). In this research, information design, navigation design, and visual design are considered in the specific context of a mobile device.

Culture and Design

User preferences for website design features are known to vary across cultures (Barber and Badre, 2001; Cyr, 2008; Evers and Day, 1997; Nielsen and DelGaldo, 1996; Sun, 2001). Cyr and Trevor-Smith (2004) examined design elements for 30 municipal websites in each of Germany, Japan, and the United States. Significant differences were found across countries for use of symbols and graphics, color preferences, site features, language, and content. In a study in which user impressions were evaluated toward eight website design features, numerous differences were detected between collectivist Japanese and Chinese users with individualist British users (Hu et al., 2004). In the current investigation participants are tested who are either Canadian or Chinese. With respect to these cultures, Singh et al. (2003) compared domestic and Chinese versions of websites for 40 American-based companies and found differences in all the cultural categories examined.

Studies of m-commerce in different countries and considering different cultures are rare, although 'an understanding of the cultural dimensions of a market can aid marketers immensely in developing appropriate m-commerce services…' (Harris et al., 2005). In response, research in the area of culture and mobility is beginning to emerge. Cross-country differences were found for adoption of mobile applications in Hong Kong, Japan, and Korea (Kim et al., 2004), between the UK and Hong Kong (Harris et al., 2005), and between France and the USA (Carlson et al., 1999). Lee et al. (2002) compared Japan and South Korea in a study of m-commerce usage, and found significant cultural differences regarding value structures of the mobile Internet and their effect on users' satisfaction.

More specifically, and with respect to information design, research comparing user preferences in Canada, the U.S., Germany and Japan for perceived access and presentation of product information on a stationary computer uncovered few significant differences between the U.S., Canada, and Germany, but significant differences ($p<.01$) between these countries and a highly collectivist[2] culture like Japan (Cyr et al., 2005). Based on qualitative comments from the study, there appeared a desire on the part of Canadians, Americans, and Germans for utility - at least as far as obtaining site information is concerned. Choi et al. (2006) examined cultural characteristics and user experience attributes in mobile data services in Korea, Japan, and Finland. Based on qualitative findings, the authors found user experience attributes correlated to the user's culture and 'Finnish participants showed a cultural profile opposite to that of the Koreans' (p. 192). For example, in the area of information design Koreans and Japanese (both collectivists), preferred large amounts of information on a single screen while Finns (individualists) preferred direct, explicit communication and reacted negatively to large amounts of content. Related to the preceding studies, like the Finns, Canadians are individualists. Alternately, Chinese are collectivists in alignment with Koreans and Japanese.

H1a: *There will be differences between Chinese and Canadian users in the perception of information design of a mobile device. Canadian users will prefer utility in information design, while Chinese prefer more detail and depth of information presented in a mobile medium.*

Regardless of culture, users prefer easy to navigate websites. In an experiment using a stationary website, Simon (2001) found that North Americans prefer navigation that enhances movement and makes the interface simpler to use. In the study by Choi et al. (2006) in mobile data services as already mentioned, Koreans and Japanese liked clear and logical ordering of menu items, while Finns mentioned they most liked search facilities. Despite the paucity of prior research on navigation design across culture, and particularly in the context of mobile devices the following exploratory hypothesis is offered.

H1b. *There will be no differences between Chinese and Canadian users in the perception of navigation design of a mobile device. Both Canadians and Chinese will prefer simple and logical navigation formats.*

User preferences vary by culture with respect to visual design of the interface. Color varies by culture. Red means happiness in China, but danger in the US (Barber and Badre 2001). When applied to Web design, color may impact user expectations of the interface as well as overall satisfaction (Barber & Badre, 2001). In a cross-cultural study on website design, a Japanese respondent indicated a preference for more pictures and an "emotional approach" (Cyr et al., 2005). In other work specifically focused on images used in website design, in qualitative analyses Canadians perceived images to have aesthetic, affective and functional qualities while Japanese respondents focused only on affective qualities (Cyr et al., 2006). Sun (2001) found that users from cultures such as China or Japan have a strong preference for visuals and aesthetic beauty of the interface. In a mobile context, Koreans and Japanese preferred colorful screen design and Finns preferred simple screen design with less emphasis on color (Choi et al., 2006).

H1c. *There will be differences between Chinese and Canadian users in the perception of visual design of a mobile device. Chinese will be more concerned than Canadians with aesthetic beauty in visual design.*

Gender and Design

Gender is frequently used as a basis for segmentation, and researchers have attempted to understand the fundamental similarities and differences between the men and women for decades (Deaux & Kite, 1987; Putrevu, 2001). Past empirical studies have shown significant gender differences across a variety of tasks and domains. For example, men often perform better than women on spatial orientation tasks, whereas females tend to score better on verbal or linguistic tasks (Simon, 2001; Deaux & Kite, 1987). Similarly, men and women differ in their reactions to visual images, affecting recall and recognition (Jones et al., 1998).

There are also gender differences in computer usage. Men and women diverge in Web acceptance, with perceived usefulness found to positively influence intention to use the Web more in men than women (Sanchez-Franco, 2006). Women use computers for collaboration and networking, while men view computers as a tool for obtaining and evaluating content (Gefen & Straub, 1997). Pearson et al. (2003) examined gender as a moderating variable to end-user computer efficacy, and found no differences between men and women although women were somewhat less confident to learn new computer applications. In other research, narrowing of differences between men and women has occurred concerning software use, anxiety, and enthusiasm (Rainer et al., 2003). Specific to mobile commerce, studies indicate that among Internet users men are predisposed to mobile adoption more than women (Yang, 2005; Brennan, 2000; Joines et al., 2003; Park & Jun, 2003; Rohm & Swaminathan, 2004). Contrary to these studies, gender differences were not detected in Spanish users related to shopping patterns and m-commerce adoption (Bigne et al., 2005).

It is anticipated the design of a website will impact user preferences, which in turn may produce different reactions between men and women (Chen & Dhillon, 2003). In one investigation in which gender and design are considered, Simon (2001) tests users' perceptions of a site, which refer to information richness, communication effectiveness, and communication interface. Women were found to have a less satisfied perception of the websites than men. Other work demonstrates differences between men and women for content and navigation (Maltby et al., 2003) and preference for color or graphics (Rodgers & Harris, 2003). In a study of website design, Cyr and Bonanni (2005) found specific information design elements (such as site organization and presentation of product information) were perceived more favorably by men than women. Further, men found the sites easier to navigate, and liked certain visual design aspects such as degree of interaction and animations more than women.

The above findings on a stationary website suggest there will be differences between the preferences of men and women for interface design in a mobile context. This assumption will be explored in the following hypotheses.

H2a. *There will be differences between men and women in the perception of information design of a mobile device.*

H2b. *There will be differences between men and women in the perception of navigation design of a mobile device.*

H2c. *There will be differences between men and women in the perception of visual design of a mobile device.*

Age and Design

Age is another common dimension used to segment consumer and user groups. There has been a growing level of interest and research in issues relating human computer interaction and age groups (Goodman & Lundell, 2005). Some researchers have focused on the unique design characteristics posed by older adults. Hawthorn (2000) lists various physical, sensory and cognitive limitations that may alter with increased age and their implications for interface design. Physical limitations, such as reduced dexterity and precision, can make the use of small and delicate input devices (as found on various mobile devices) more difficult. Sensory limitations can create limitations for the design of computer output and cognitive limitations can affect the design of the interface itself. For example, cognitive spatial ability has predicted computer performance (Kelley and Charness 1995), and was demonstrated to decline with increasing age (Salthouse, 1992). In other research, age affected the retention of computer training (Brown, 2001), and confidence in learning new applications (Crosby et al., 2003). Older employees generally exhibited a less positive attitude towards computers (Brown, 2001), and were less satisfied users (Simmers & Anandarajan, 2001) than younger employees. It is expected that well designed visual cues such as text links and icons are able to support the needs of older users. The format for organizing Web contents and the amount of information appearing on a screen enable higher performance for older users as their visual search skills and selective attention diminish (Ellis & Kurniawan, 2000).

As with gender, studies that investigate mobile use or m-commerce with consideration of age or design are few. Stroetmann et al. (2002) found that 43% of elderly people surveyed had at least some difficulty with mobile devices and 21% had considerable difficulty because of some physical or cognitive impairment. In a study of Swedish teenagers, Weilenmann and Larsson (2000) reported that young people use a mobile phone in radically different ways from more mature adults. Younger users use a mobile device more for expression than for information, and for social purposes rather than for coordination or efficiency. In a study with Spanish users, younger people are more predisposed to m-commerce adoption than older Internet users (Bigne et al., 2005). In a report on mobile use in India (MACRO 2004), limited adoption of mobile devices among older users resulted from small buttons on the handset and tiny screens that impede user visibility. Goodman et al. (2005) found that text, speech, and photographs were all effective ways to present landmark information to older users using a mobile navigation aid.

In this investigation we are interested to examine design characteristics (such information design, navigation design, and visual design) as outlined by Garrett (2003) for a mobile device, in this case an Internet enabled phone. To our knowledge this is the first attempt to systematically examine these design features and how they may differ for older or younger mobile users. To develop some understanding in this area, the following exploratory hypotheses are offered.

H3a. *There will be differences between older and younger users in the perception of information design of a mobile device.*

H2b. *There will be differences between older and younger users in the perception of navigation design of a mobile device.*

H3c. *There will be differences between older and younger users in the perception of visual design of a mobile device.*

Design and Satisfaction

For many years customer satisfaction has been studied in physical environments (Balasubramanian et al., 2003; Parasuraman et al., 1988; Oliver, 1980 and 19991999). More recently, research into consumer satisfaction has turned to the Web domain and examines 'stickiness' and 'the sum of all the website qualities that induce visitors to remain at the website rather than move to another site' (Holland & Baker, 2001). According to Anderson and Srinivasan (2002), e-satisfaction is defined as the contentment of the customer with respect to his or her prior purchasing experience with a given electronic firm. In the present research we adapt the definition for online satisfaction presented by Anderson and Srinivasan to suggest mobile satisfaction refers to contentment of the customer with the experience of using the mobile interface. However, there is no requirement for completion of a purchase in the current context. This definition is in alignment with Chae et al. (2002) who examined information quality related to user satisfaction for mobile Internet services.

Online satisfaction motivates online shoppers to stay at the site and return to the site in the future (Flavian et al., 2005; Bhattacherjee, 2001; Doll & Torkzadesh, 1988; McKinney et al., 2002) thus yielding a loyal customer outcome. In research into stationary websites, customer satisfaction is affected by content and context of the website (Flavian et al., 2005; Teo et al., 2003). More specific to information design, Szymanski and Hise (2000) discovered that product information and site design are critical to creating a satisfying customer experience. The experience of online shopping can be affected by the richness of product information presented (Palmer, 2002; McKinney et al., 2002), and is a dominant concern of the user (Kateranttanakul & Siau, 1999; Pitt et al., 1995; Zhang et al., 2000). A positive navigation experience and perception of a well-designed site may likewise result in online consumer satisfaction (Agarwal & Venketesh, 2002; Fogg & Tzeng, 1999; Palmer, 2002; Fogg et al., 2002; Hoffman & Novak, 1996; Koufaris, 2002; Nielsen, 2001), an enjoyable online shopping experience (Childers et al, 2001), and sales (Lohse & Spiller, 1999). Yoon (2002) found navigation functionality resulted in satisfaction, and induced Web visitors to remain at the site. Lohse and Spiller (1998) demonstrated that designing online stores with friendly user interfaces positively influences traffic and sales. Cyr (2008) found information design, navigation design, and visual design to all positively impact satisfaction for users from multiple countries.

While design research is limited within the mobile context, Tarasewich (2003) concluded: '[A]esthetics, along with usability, may also be part of designing an overall enjoyable user experience with mobile devices' (p. 12). Jiang and Benbasat (2003) found that mobile interface features can positively influence users' attitudes regarding product presentations. Graphical user interfaces, information architecture, and content all contributed to differences in perceived satisfaction with mobile data services (Choi et al., 2006). The preceding considerations lead to the final hypotheses:

H4a. *Perception of information design of a mobile device will impact user perceived satisfaction with the mobile device.*

H4b. *Perception of navigation design of a mobile device will impact user perceived satisfaction with the mobile device.*

Figure 1. Research model for mobile services

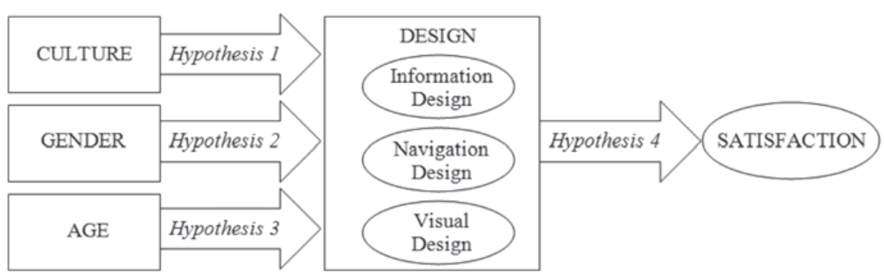

Table 1. Country comparisons (Source: based on Hofstede, 1980)

Country Dimension	Canada	China
Power Distance	Low (39)	High (80)
Uncertainty Avoidance	Low (48)	Medium (60)
Masculine	Medium (52)	Medium (50)
Individualism	High (80)	Very Low (20)
Long-Term Orientation	Very Low (23)	Very High (118)

H4c. *Perception of visual design of a mobile device will impact user perceived satisfaction with the mobile device.*

The above hypotheses as examined in this research are visually depicted in Figure 1.

RESEARCH METHODOLOGY

Participants

Sixty participants were recruited who were either Chinese or Canadian in origin (30 in each category). These countries were chosen to represent diverse cultural characteristics as per Hofstede (1980). Refer to Table 1.

Participants were also categorized by gender and age. Consistent with Aarnio et al. (2002), younger participants were 34 and younger and older participants were 35 or older. A relatively small sample size of 30 was chosen for each group due to the individualized and in-depth requirements of the data collection process. To participate, individuals must have used a cell phone for at least one year. In fact, all participants in the study were experienced users, and had owned a cell phone for approximately 4.5 years. Demographics of the sample appear in Table 2.

Experimental Site and Device

Given the emphasis on aesthetics in usability, an attractive site was required, without interference from a slow or faulty live Internet connection. Most WAP sites in North America and Europe are primarily text based, however the Lonely Planet offered some visual treatment (www.lonelyplanet.com with access from a mobile phone at wap.lonelyplanet.com). Therefore the City Guide version of this site was chosen for the experiment and further enhanced. The site for this study featured a colored background and text cells, as well as photographs, maps and icons, among other features. Each version of the site was created in both English and Chinese. For the Chinese version, site contents were translated to Chinese, 'back-translated' from Chinese to English, and then this version was compared with the original English version to verify content equivalence. Screenshot pages appear in Appendix A. Testing occurred on a Nokia 6600 Internet enabled cell phone. This

Table 2. Participant demographics

	Canadian (n=30)	Chinese (n=30)
Age	< 35: 67% ≥ 35: 33%	< 35: 60% ≥ 35: 40%
Gender	Male: 53% Female: 47%	Male: 43% Female: 57%
Highest level of education	High school: 40% Technical degree: 3% Undergraduate/College: 43% Masters/Doctorate: 13%	High school: 27% Technical degree: 3% Undergraduate/College: 53% Masters/Doctorate: 17%
Time spent online/week	22 hours	17.4 hours
Time owned a cell phone	4.8 years	4.4 years
Mobile Internet browsing experience	20%	17%
Use of the mobile Internet (if available)	Buy movie/concert tickets: 33% Download games/ring tones: 40% Check news: 50% Browse places to eat, shop, etc.: 47% Other: 33%	Buy movie/concert tickets: 30% Download games/ring tones: 60% Check news: 67% Browse places to eat, shop, etc.: 67% Other: 7%

phone was considered very suitable to the aims of the investigation as it has one of the largest screens on the market and has a superior color display (65,536 TFT) capable of laptop quality images. The interface included a joystick option for easy navigation.

To prevent problems with download and browsing delays typical of a real website using WAP technology, website pages for the Lonely Planet were downloaded and saved locally on the cell phone. Based on feedback obtained from a pilot focus group (of 6), participants were not aware of this manipulation and perceived the connection to be '*real*'. Important to this study, saving the site locally allowed the content to be modified and the display speeds to be controlled.

Experimental Tasks

The pilot study with 6 participants was used to pretest potential tasks and the experimental protocol including survey items and interview questions. Participants in the pilot study were initially asked to perform three information retrieval tasks: finding movie listings at a local theatre, choosing a restaurant in a different city, and booking a hotel in a different city. It was decided the restaurant task was most suitable because it was preferred by the pilot subjects and afforded excellent visual design opportunities. For the restaurant task, photos of the venue's interior as well as the map showing the location were included.

In the full study, each participant went through the experiment individually, under the supervision of a research investigator. For Chinese participants, all documents were translated and back translated, and a translator was available as required. The session began with a brief introduction and completion of a background data sheet, followed by familiarization with the Nokia 6600 device including a written summary of key functions. Once it was determined participants were comfortable with the device they were read the following narrative:

Imagine that you have just arrived in San Francisco to meet up with an old friend. Your friend has suggested that you select a restaurant on your cell phone, and call her back with the address. Use the bookmarked CityGuide site to accomplish this task. Spend as much time as you need browsing through the featured listings for San Francisco. There is no need to actually write down any information or make any calls. Just let me know what your selection is when you're finished.

The device was then handed to the participant with the browser opened at the introductory page of the site. The site listing for San Francisco featured four restaurants. Participants first completed the task, and then responded to a survey and were interviewed regarding their experience. At the end of the experiment, participants were debriefed and received a $20 honorarium for their time.

Survey Instrument

Following the completion of the experimental task, subjects were asked to complete a paper-based survey. In this section, we provide an overview of the survey measurement items, focusing on its content and construct validity.

Content validity considers how representative and comprehensive the items are in creating the experimental constructs. Validity is assessed by examining the process by which the construct items were generated (Straub, 1989). Constructs should draw representative questions (items) from a universal pool (Cronbach, 1971; Kerlinger, 1964). In this research, survey items were adapted from previously validated work on Information design (Cyr et al., 2004 and 20052005), Navigation design (Cyr et al., 2004 and 20052005), Visual design (Cyr et al., 2004 and 2005;2005 van

Table 3. Principle components analysis and reliability

		ID	ND	VD	SAT

	SAT4	.408	.279	.290	**.646**

Notes: ID=Information Design; ND=Navigation Design; VD=Visual Design; SAT=Satisfaction

der Heijden, 2003), and Satisfaction (Cyr et al., 2004 and 20052005). All items were constructed as agree-disagree statements on a seven-point Likert scale. The complete survey appears in Appendix B.

Construct validity assesses the extent to which a construct measures the variable of interest. In other words, there should be high correlations between items of the same construct (convergent validity), and low correlations between items of different constructs (discriminant validity) (Straub, 1989). Results of the principal components analysis with varimax rotation appear in Table 3. The loadings for navigation design, visual design, and satisfaction construct items exceed recommended thresholds (Hair et al., 1998). However information design had two items (ID3 and ID4) that had high cross-loadings with items in the visual design construct. As such, ID3 and ID4 were removed from our analysis in order to maintain discriminant validity.

Discriminant validity can also be assessed by the average variance extracted (AVE) for each construct. As shown in Table 2, the AVEs were all above the recommended 0.50 level (Fornell & Larcker, 1981), which meant that more than one-half of the variances observed in the items were accounted for by their hypothesized factors.

Construct reliability (internal consistency) of the four factors was examined using Cronbach's α-value. As shown in Table 2, α-values ranged from 0.61 (for information design) to 0.89 (for visual design). Rivard and Huff (1988) suggest that this measure for reliability should be higher than 0.5 and ideally higher than 0.7. Navigation design, visual design and satisfaction α-values are well past this recommended threshold, and the α-value for information design (with its two items dropped) is also in an acceptable range. Therefore, our survey instrument encompassed satisfactory content validity (as evidenced from drawing construct items from existing validated literature); satisfactory convergent validity (as evidenced from high item loadings and construct reliability); satisfactory discriminant validity (as evidenced from low cross-loadings of factor items and the AVE for each factor); and satisfactory construct reliability (as evidenced from Cronbach's α-values).

Interviews

Following the completion of the survey, subjects were asked open-ended questions in a tape-recorded interview. The interview questions were meant to solicit additional information about the participants' experiences with the experimental task and interface. The questions probed how participants liked the design of the site, what they would change, and whether or not they found the device useful.

Responses were content analyzed and coded using Atlas.ti. This software provides an effective means to analyze qualitative data such as interview transcripts. The qualitative analysis process consisted of the following steps: (1) data preparation (i.e. interview transcription and formatting); (2) in vivo coding (use of participants' words as code labels) and open coding (use of arbitrary labels for code labels); (3) category and concept building in which semantic relationships between codes are identified to build higher conceptual abstractions; and (4) theory building based on interpretation of the results.

RESULTS

The descriptive statistics and correlations for the perceptual constructs are shown in Table 4. Each of the design variables (ID, ND and VD) was correlated to each other, as well as to overall satisfaction. From the demographic variables, only age is positively correlated with visual design.

Overall, respondents have a rather favorable impression of the mobile interface, with mean

Table 4. Descriptive statistics and correlations

	Mean	Std. Dev.	ID	ND	VD	SAT	GEN	CUL	AGE
ID	5.43	1.04							
ND	5.73	0.90	.37***

scores of over 5 out of 7 for information design (ID), navigation design (ND), and visual design (VD). The mean score for satisfaction is 4.98, also indicating overall satisfaction with the site. To probe these results further, a word count was run on transcribed interviews using the atlas.ti software. The word 'easy' appeared 69 times, mostly in response to the question 'Try to describe the navigation experience on the site'. As such, the majority of users find the navigation of the device easy. One respondent elaborates, '*[U]sing the joystick was pretty straightforward, once I remembered to go left and right to go up the links. It was more intuitive to use the scroll button up or down…*'

Although information design receives a relatively high mean score (5.43), more than half the respondents thought there could have been more information about the restaurants on the site. This split into two category codes: one related to not enough information for each restaurant, which typically was lack of a menu (code *menu*) and two, not enough choice of restaurants (under the code *choice*). In terms of visual design of the site, the following quote captures some of the favorable sentiments as expressed by a number of users: '[E]*asy to use, attractively displayed, something that awes people, this display is very graphically appealing. I really want to play with this.'* Another user comments: *'The colors were good. The colors were actually fairly robust. Resolution seemed to be pretty good.'*

Tests of Culture, Gender, and Age as Moderators

T-tests of differences between culture, gender, and age group means for design and satisfaction are shown in Tables 5, 6, and 7 respectively.

Additionally, interview data was coded using two methods: (i) in vivo (using the participant's exact words as the basis for a code), and (ii) open coding (using arbitrary labels to code the data). Interview responses were systematically categorized in each design area (information, navigation and visual design). Altas.ti was used to create a concept map for the design areas, highlighting the actual number of responses in each code based on gender and culture. Refer to Appendix C. Although the numbers are relatively low, they signify response trends between the groups. In addition, representative quotations are included. Further, more theoretical themes were created from the emerging concepts, across the design areas. The main themes from our interview data were:

- **Information breadth:** The number of alternative (restaurant) choices. This is encapsulated by comment such as 'choices are limited' and unmet expectations for 'a lot of restaurants represented'.
- **Information depth:** The amount of detail for each alternative (restaurant) choice. This is encapsulated by participants seeking 'detailed menus', 'prices', 'famous dishes', 'parking', 'exterior shots', 'reviews' and 'hours of operation'.
- **Visual ease:** Utilitarian view on the interface design's capability to facilitate the task. This is captured through comments such as 'adequate resolution', 'easy to read' and 'easy to look at'.
- **Visual beauty:** Hedonic view on the beauty of the interface design. This is captured through comments such as 'cute' design, 'should be more charming', 'put some music', and 'animation would be good'.
- **Navigation layout:** The layout of the information within the site. Captured by comments such as 'laid out in a logical way', and too much 'scrolling'.

Table 8. Summary of interview analysis across culture, gender and age groups

Design Area	Culture	Gender	Age
Information Design	Canadian: focused on Information Breadth Chinese: focused on Information Depth	Male: no noticeable patterns Female: focused on Information Depth (in particular, Chinese females)	Young: focused on Information Breadth Old: commented on both Information Breadth and Information Depth, with more focus on Depth
Navigation Design	Canadian: commented on both Navigation Layout and Challenges (in particular, Canadian women focused on Navigation Challenges) Chinese: very few comments on navigation	Male: some comments on Navigation Layout. Female: focused on Navigation Challenges (in particular, Canadian women).	Young: very few comments on navigation Old: some comments on Navigation Challenges
Visual Design	Canadian: focused on Visual Ease (in particular, Canadian men) Chinese: focused on Visual Beauty (mostly providing suggestions to augment beauty)	Male: No men commented on Visual Beauty; Canadian men commented on Visual Ease Female: focused on Visual Beauty (in particular, Chinese females)	Young: some comments on Visual Ease Old: commented on both Visual Ease and Visual Beauty (females only for Visual Beauty).

- **Navigation challenges:** Navigation/interaction challenges mostly stemming from inexperience with the new technology. Encapsulated by comments such as ‘counterintuitive joystick’ and not convenient to ‘press the left side to select the options’.

Table 8 summarizes the analysis of the interview transcripts across the above emerging themes and individual differences (culture, gender, age).

Based on the survey data, it is surprising no statistically significant differences are evident for culture or gender. However based on the qualitative analysis of the interview data some differences in these categories are indicated.

These results support H1a that Canadians prefer utility of information design, while Chinese prefer more detail and depth of information. Canadians were much more disappointed with the number of restaurant choices (Information Breadth) than Chinese, who focused on the lack of restaurant details (Information Depth). This Chinese focus on Information Depth was particularly evident among Chinese women. H1b was also generally supported in that both Canadians and Chinese prefer simple and logical navigation formats. In the case of Canadians they thought navigation could in fact be simpler, and the Chinese made few specific comments. Finally, qualitative results also support H1c. It was predicted Chinese would be more concerned with aesthetic beauty of the mobile interface than Canadians. In fact, Chinese (women only) even commented on how to augment the beauty of the interface, and Canadians focused more on visual ease.

It is interesting to note that no male from either culture made comments on the visual beauty or hedonic elements of interface design. However there were some cases where women not only commented on their hedonic preferences, but also made distinctions of what they prefer versus what they think men prefer. Overall, while our quantitative analysis rejects hypothesis 2 concerning differences in gender, our in-depth qualitative analysis suggests there may be some interesting differences in these categories.

Some support is found for hypothesis 3. Using survey data, statistically significant differences exist between older users (35 or older) and younger users (under 35) for visual design, with older respondents indicating the design of the mobile

interface more appealing. Generally speaking, older respondents seem more impressed with the novelty of the device and its design than the younger group. This is evidenced in the following comment from an older subject: '*The newness of it, it's captivating. Being efficient is fun sometime. Not having to wade through a whole bunch of stuff. Look at this, look at what it can do, you can do it really easily, and you can get the information before everybody else does.*'

Predicting Satisfaction

Regression analysis was performed to assess the determinants of satisfaction based on main effects and interaction effects of the variables in this research. Gender and culture categorization was straightforward, where dummy variables represented males/females and Canadian/Chinese participants. Age was also coded as a dichotomous variable for clarity in presentation (Morris et al., 2005). Participants who are 34 years of age or younger were categorized as 'younger', while those 35 or older were placed in the 'older' category (as per Aarnio et al., 2002). Morris et al. (2005) suggested that gender differences in technology perceptions are more pronounced among older workers, and the interplay between key demographic variables should be examined in addition to investigating isolated demographic characteristics. This notion is supported by others in the information systems field (Butler, 2000; Venkatesh et al., 2000), as well as the field of psychology (Nosek et al., 2002; Kubeck et al., 1996). Therefore, in Table 9 the regression analysis examines various combinations of three-way and four-way interactions between demographic variables (e.g., visual design X gender X age).

In general, results of the regression analysis in Table 9 support hypothesis 4 that design elements do impact satisfaction with mobile services.

The effect size of independent variables on a dependent variable can be determined by comparing the R^2 of the dependent variable with and without the presence of each independent variable (Chin, 1998). The calculation for effect size (f^2) is as follows:

$$f^2 = \frac{R^2_{\text{included}} - R^2_{\text{excluded}}}{1 - R^2_{\text{included}}}$$

The effect size of perceived information design, navigation design and visual design on satisfaction were $f^2=0.09$, $f^2=0.08$ and $f^2=0.23$, respectively. Cohen (1988) provides the following criteria for interpreting effect size: (i) for small effect size, $0.02<f^2\leq 0.15$; (ii) for medium effect size, $0.15<f^2\leq 0.35$; and (iii) for large effect size, $f^2>0.35$. Therefore, both information and navigation design were shown to have a small effect size on satisfaction, while visual design can be classified as having a medium effect size on satisfaction.

The only interaction effect shown to have a statistical impact on satisfaction is information design by age by culture. Not all groups were equally satisfied with information provided at the site. This is supported in our qualitative analysis. Canadians were primarily concerned about the limited number of restaurant options (Information Breadth), whereas Chinese sought more detailed information for each of the restaurant choices (Information Depth). As one Chinese participant noted, '*You need to know price of the restaurant, the surroundings, and what the location and street looks like, but maybe I would have to call them to get information and details*'. In contrast, a Canadian participant commented: '*I was expecting there would be a lot of restaurants represented. For San Francisco I would be disappointed, I wouldn't trust the source'*. This was particularly evident among the older participants.

DISCUSSION AND CONCLUSION

Egan (1998) makes the case for exploring individual differences in interface design, and claims 'differences among people usually account for much more variability in performance than differences in system designs or differences in training procedures' (p. 543). Individual differences may affect what users seek in a system's interface, and how they interpret such interfaces. Elements of a user interface appropriate for one group may not be appropriate for another.

For mobile devices, evidence of the impact of individual differences on design and satisfaction has been preliminary, scattered, and incomplete. In fact, the majority of previous research tends to examine the *adoption* of mobile devices by culture (Harris et al., 2005; Kim et al., 2004; Carlson et al., 1999), gender (Yang, 2005; Brennen, 2000; Joines et al., 2003; Park & Jun, 2003; Rohm & Swaminathan, 2004) or age (Wielenmann & Larsson, 2000) rather than based on design considerations.

In contrast, the current research explores user perceptions of mobile *design* by culture, gender and age. This has included a focus of information design, navigation design and visual design and how each impacts user satisfaction with an Internet enabled cellular phone. Our exploratory analysis using both quantitative and qualitative data reveals some interesting differences for culture and age between user groups related to our three mobile design dimensions and satisfaction. Equally interesting is that there are no gender differences for the mobile device as tested.

In the realm of information design, overall Canadian and Chinese users felt there was adequate information presented on the mobile device, but each group was attentive to different types of information. Canadians focused on 'Information Breadth' (more choice of alternative restaurants) and the utility of information design, while Chinese focused on 'Information Depth' (more detail about the existing choices). This finding is in alignment with the qualitative results of Choi et al. (2006) who discovered that collectivist Koreans and Japanese preferred large amounts of detail on a single screen. With respect to gender and information design, no specific patterns emerged for men however women tended to focus more on 'Information Depth', especially Chinese women. This finding suggests women more than men desire detailed information content, perhaps related to different modes of information processing (Maltby et al., 2003). With respect to age, younger participants focused on 'Information Breadth' while older users desired both breadth and depth of information, with more emphasis on depth. Taken collectively, younger Canadian users were most concerned with 'Information Breadth' while older Chinese females were most focused on 'Information Depth'. These results have implications for mobile interface designers who aim to best connect with users.

On the stationary Internet, there is evidence that preferences for visual design vary by culture (Cyr, 2008; Cyr & Trevor-Smith, 2004). Users from collectivist cultures such as China desire visuals and aesthetic beauty of the interface, with emphasis on "affective" qualities (Cyr et al., 2006). On a mobile interface Choi et al. (2006) similarly found that collectivist Koreans and Japanese preferred colorful screen design, while Finns preferred simpler, less colorful screen design. Results from the current investigation parallel these earlier studies. In the area of visual design, Canadians focused on Visual Ease (utilitarian elements of design) while Chinese commented more on the 'beauty' of the design. Related to gender, men in both cultures and age groups were more concerned with 'Visual Ease' while women were more interested in 'Visual Beauty' and more aesthetic elements of the interface.

Almost all participants found the mobile interface relatively easy to use and navigate. The sites are not deep, are laid out in a logical way, and the joystick is easy to master. Chinese participants had little to say about navigation, while Canadians women and older users generally commented on challenges of navigation the interface. This finding is aligned to other work in which women found stationary websites more difficult to navigate (Cyr & Bonanni, 2005), or where physical limitations may have implications for interface design with older users (Hawthorn, 2000).

Consistent with findings for the stationary Internet, it is not surprising that in this investigation design elements impact satisfaction in a mobile service context. Further, the current work is consistent with Chae et al. (2002) who found that information quality of mobile services contributed to satisfaction. However, Chae et al. examined different elements of the mobile interface than in our investigation. Collectively, these findings support the assertion that regardless of technology or device, the interface is often considered the most important component of the entire system to the end-user (Sarker & Wells, 2003), and plays an important role in user attitudes (Bidgoli, 1990). As such, further research related to effective mobile design has commercial implications for m-commerce and is aligned to investigations of effective website design in e-commerce (Agarwal & Venkatesh, 2002; Fogg & Tzeng, 1999; Hui & Triandis, 1985; Morgan & Hunt, 1994; Schultz, 2003).

This is an initial exploratory study with a limited sample size, representing only two cultures. Although participants are representative of the desired cultural groups, they may not fully represent the socio-economic group within their country. It is recommended that follow-up studies draw samples from larger populations, and from additional culture groups. Also, usability evaluations themselves may be culturally bound. As Yeo (2001) points out, participants from various cultures are prone to provide false statements during usability evaluations to allow the designer to 'save face'. Research is needed to develop usability and research methodologies that accurately reflect personal opinions and preferences across cultures. Further, designers tend to ignore the role culture may play in the design of the interface (Sheridan, 2001), in particular within the Web context (Jagne et al., 2005). While many studies have been inconclusive, cultural factors deserve further investigation (Kwon & Chidambaram, 2000). At the very least, researchers and designers will ideally seek to better understand design elements that promote cultural attractiveness.

It is noteworthy that only one mobile application (a restaurant selection) and only one WAP site (lonelyplanet.com) are used in this experiment. The site offered some visual treatment, but has a narrow structure and simple layout. A more complex site with a deeper hierarchy may reveal more pronounced differences across diverse groups. Future research should consider multiple designs across multiple mobile applications. A positive feature of this investigation is the application of design elements as outlined by the design community (Garrett's 2003 categorizations for information design, visual design, and navigation design) to a mobile treatment. Further, in a nascent area of study as represented here, a strong point of the investigation is the use of both quantitative and qualitative methodologies. In addition to surveys, interview data was evaluated using atlas.ti software to provide a systematic evaluation of words or phrases into categories relevant to this investigation. The use of atlas.ti afforded deeper insights into the user experience than survey data alone can provide.

This research is an important first step in understanding the impact of individual differences on the design and satisfaction of mobile services. This relatively unexplored area is worthy of future attention. The quest for further knowledge as to how culture, gender and age impact technology use and satisfaction implies appreciation that these relationships are dynamic, and subject to continuous transformation (Simon, 2001). Enhanced understanding of subtle dimensions related to specific user groups will eventually enable fulfillment of expectations for optimal anytime and anywhere services.

ENDNOTES

1 Throughout this paper the terms ‘portable’, ‘handheld’, ‘mobile’ and ‘small-screen’ refer to essentially the same type of device, typically called a ‘smart phone’. Also, the term ‘mobile Internet’ refers to accessing the Web directly on a small-screen, handheld, or mobile device that may be connected to the Internet.

2 The work by Geert Hofstede (1980) outlines 5 cultural dimensions: (1) Power distance - extent to which a society accepts unequal distributions of power in organizations and institutions. (2) Uncertainty avoidance - how societies accommodate high levels of uncertainty and ambiguity in the environment. (3) Masculinity-Femininity - in feminine societies there is an emphasis on quality of life and relationships; cultures that focus on material success and assertiveness are considered more masculine in orientation. (4) Individualism-Collectivism - in an individualist society individuals are expected to consider personal interests over interests of the group and individual decision-making is valued; in a collectivist culture the good of the group is more likely to be considered.

(5) Time Orientation - whether the focus in on short-term vs. long-term considerations. For a further elaboration of Hofstede's cultural dimensions, refer to Hofstede (1980) or Simon (2001).

APPENDIX B. DESIGN SURVEY

Following are the statement used in the survey. Each was answered on a 7-point Likert scale from strongly disagree to strongly agree.*Information Design* [Sources: Cyr et al. 2005; 2004]

ID-1: I find the information logically presented.

ID-2: All service options, service attributes and restaurant information are well presented.

ID-3: I find the information to be well organized.

ID-4: The presentation of information is effective.*Navigation Design* [Sources: Cyr et al. 2005; 2004]

ND-1: This browser provides good navigation facilities to information content.

ND-2: I can easily navigate the CityGuide site.

ND-3: I find the CityGuide site easy to use.*Visual Design* [Sources: Cyr et al. 2005; 2004; van der Heijden 2003]

VD-1: The screen design (i.e. colors, boxes, menus, etc) is attractive.

VD-2: This site looks professionally designed.

VD-3: The graphics are meaningful.

VD-4: The overall look and feel of the site is visually appealing.*Satisfaction* [Sources: Cyr et al. 2005; 2004]

S-1: This site appeals to me emotionally.

S-2: This service completely fulfills my expectations.

S-3: This service satisfies my needs well.

S-4: Using this service is satisfactory overall.

Chapter 2.2
Paralingual Web Design and Trust in E-Government

Roy H. Segovia

James Beatty
San Diego State University, USA

ABSTRACT

Can Web design improve the way governments serve their constituencies through the use of information technology [i.e., e-government]? This article proposes that the use of paralingual Web design can overcome possible trust issues in e-government with bilingual populations. An experiment was conducted where active e-government Web pages were converted to paralingual format and then site visitors were surveyed regarding their trust in the content and readability. The results of the experiment show that trust was improved for the minority language speakers, while the majority language speakers remained neutral with neither group indicating significant decrease in readability. These findings have important implications for societies with large bilingual or multilingual populations, where issues of trust among minority speakers and majority speakers may exist, as they indicate that paralingual Web design can help reduce these trust issues.

INTRODUCTION

Electronic government (e-government) is the use of Information and Communication Technologies (ICT), including the Internet, by government organizations to facilitate providing information and services to their constituents. E-government Web sites provide everything from basic information about governmental bodies and issues, to online services such as registering vehicles and applying for employment and for permits. More recent e-government services include econsultation, which is citizen participation and response to forthcoming consultations and decisions on matters of public interest (Jadu, 2005). The impetus to implement e-government can be attributed to cost control and improved service to citizens. Another driver is government's growing awareness of the need to attain more democratic governance (Coleman and Gotze, 2001; OECD, 2001), coupled with a widespread public interest in the potential of ICT to empower citizens and to increase government accountability and transparency (Hart-Teeter, 2003). An example is the United States E-Government initiative targets use of improved Internet-based technology to make it easier for citizens and businesses to interact with the government, save taxpayer dollars, and streamline citizen-to-government communications (USOMB, 2005). These many drivers make it likely that e-government will be a lasting ICT application leading e-government system designers to look for tools and methodologies that will ensure their acceptance and use by the intended users.

This article introduces one such potential design methodology, paralingual Web design, and uses an experiment to test this design methodology to see if it has potential for improving system acceptance and success. Paralingual is a Web design methodology for presenting information in more than one language. Paralingual Web design involves placing content in the desired languages but instead of having separate pages for each language as is common in a bi or multilingual Web design, the bi or multilingual content is placed side by side on the same page. The inspiration for this article is the trend towards localization in ecommerce systems and a concern that there may be a localization issue for e-government when the target population is bi or multilingual. Localization is defined by the Localization Industry Standards Association (LISA, 2008) as the process of modifying specific products or services for specific markets. In the case of e-government this involves tailoring e-government Web sites to fit the constituent market and in the case of a constituent market that speaks more than one language, allowing for these multiple languages. The concern driving this experiment is that there may be a trust issue affecting the success/adoption of e-government should these systems fail to take into account the bi or multi lingual aspects of their constituents.

A premise of information systems, IS, is that for an IS to be successful the intended system users must "use" the system where Rai et al. (2001) consider "use" to be the consumption of the outputs of the IS by the users as measured in terms such as frequency of use, amount of time of use, numbers of access to the IS, usage pattern, etc. General thinking is that the more an IS is used, the more successful the IS. Two of the more widely accepted IS success/acceptance models, the DeLone and McLean (1992 and 2003) IS Success Model and the Davis (1989) Technology Acceptance Model, TAM, incorporate "use" as a measure of success (DeLone and McLean) or successful adoption (TAM) through constructs such as Intent to Use, Perceived Usefulness, and Perceived Ease of Use.

Several authors (Gefen, et al., 2002; Tan, et al., 2005, Tan, et al., 2008, Warkentin, et al., 2002) suggest that use of e-government is influenced by the trust that potential users have with e-government. This article hypothesizes that this trust in e-government, and thus subsequent use, can be increased in bi and multi lingual societies by using paralingual Web design. This allows readers who are bilingual to easily see both versions and readily determine if the same information is being said in each version. It is expected that trust will be increased through this citizen validation process.

The contribution of this research is showing designers of e-government Web pages how the Web pages can be designed to improve trust in a bi-lingual constituency. While this research did not test this design approach in a multi-lingual environment it is expected this design can also be applied to e-government Web pages for these constituencies.

LITERATURE REVIEW

This article draws from three main bodies of literature, the trust, paralingual, and IS acceptance/success literatures. These literatures are summarized below and provide the theoretical foundation for the article. The trust literature is presented first as it provides the issue of concern for the article. The paralingual literature is second to provide the background for why the proposed design methodology is a good solution for the trust issue. The IS acceptance/success literature is provided third as it helps provide the framing for the experiment.

Trust can be defined as "the subjective assessment of one party [trustor] that another party [trustee] will perform a particular transaction according to his or her confident expectations, in an environment characterized by uncertainty" (Ba and Pavlou, 2002, p. 245.) For e-government this means users trusting that the e-government service is providing correct information, that data will be protected, and that transactions will be conducted in a secure manner and recorded appropriately.

Trust in government has historically been problematic in the United States of America as constituent citizens are known to have a high level of distrust in their governing bodies. Trust in government has been declining for more than three decades and has been the topic of a substantial amount of research in political science (Levi and Stoker, 2000; Hibbing and Theiss-Morse, 2002). In the state of California, a recent study exposed an unexpectedly high level of distrust in government by California citizens. During 2004, a series of dialog-oriented seminars were held by Viewpoint Learning in various locations in California. One of the seven major findings of the study was that an underlying issue was profound mistrust of government and elected officials. Furthermore, this mistrust was more intense and persistent than expected, outstripping the levels that have been measured by polls and focus groups (Rosell, Gantwerk, and Furth, 2005).

In addition to the trust issues above, there are known issues with trust in e-government Web sites. This is clearly the effect of the general mistrust by citizens in their government bodies, as mentioned previously. The principal reason given for mistrust of the Web is an artifact of the internet itself. Namely, the internet is now perceived to be beyond the control of the hosts and providers in terms of security and trust. Despite the use of lock icons, digital signatures, passwords, privacy policy statements, and other security techniques, internet users feel that hosts and providers have lost control of the digital data transport medium as well as the software infrastructure that supports it, impeding the growth of e-government (Mercuri, 2005.) To counter this, the International Telecommunication Union (ITU) is providing support for national e-government projects including enhancing security and trust in the use of public networks (Khalil-babnet, 2005).

Improving trust in government and e-government is a critical issue. In the study by Viewpoint Learning, citizens voiced a strong desire to find constructive solutions to problems facing the state (Rosell, Gantwerk, and Furth, 2005). In a geographical area with a high proportion of bilingual speakers, usage of e-government Web sites may be improved in the same way as has been shown effective in electronic commerce (ecommerce). That is, with regard to language issues, researchers have found that customers are far more likely to buy products and services from Web sites in their own language, even if they can read English well. Furthermore, attention to site visitors' needs should be an important consideration in Web design because such attention can help a site build trust with customers (Schneider, 2003). Gassert (2004) suggests building trust through knowledge by using ICT for better education and information. Additionally, LaVoy (2001) supports the use of e-government as a way of improving trust by improving accountability. Finally, Gefen, et al. (2002) view trust in government as the main driver for e-government adoption. Their analysis show data privacy concerns create the biggest barrier to adoption of e-government. While this form of e-government service, online tax service, consists of real transactions, the trust issue dealt with in this research comes even before citizens attempt such transactions. Namely, the citizens must be given a reason to simply trust in the information that is on a government Web site.

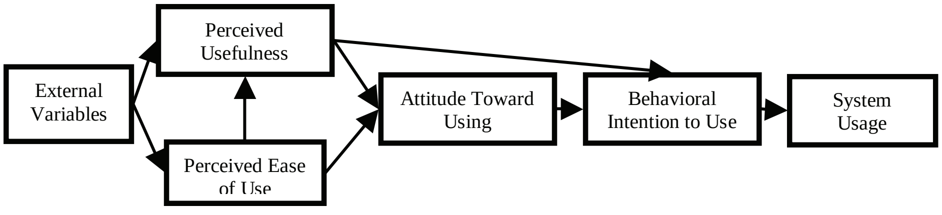
One of the earliest known examples of written multi-language information is the Rosetta Stone. According to Wikipedia (2006a), this archaeological artifact is a granite stone with writing in three different written scripts dated to about 200 BCE (Before Common Era, essentially the same as BC). It contains Greek, Demotic Egyptian, and Egyptian hieroglyphics. The message in the three scripts is the same and is a decree by the Egyptian ruler Ptolemy V regarding taxes and temple construction. The purpose of having the message written in three languages adjacent to each other was to solve a difficult linguistic problem..

A contemporary example of multi-language dissemination of important information is a requirement in the California Labor Code about employers posting worker information in English and Spanish. According to the Labor Code, several important documents, such as the Notice of Workers Compensation Coverage, must be posted in Spanish and English whenever there are employees of Spanish descent (California Labor Code, 2006.) There are similar requirements regarding Minimum Wage, Pregnancy Disability Leave and the California Family Rights Act (OSHA4LESS.COM, 2006)

The term “paralingual” is used to define the layout of information using two sets of text in different languages on the same page, such as in a Web page. The term was coined as an extension of the word “bilingual.” Para is a Greek prefix that means beside, near, or alongside (Wikipedia, 2006). Therefore, paralingual refers to two languages adjacent to each other on the same page. Paralingual Web pages are almost non-existent on the Web. Although many Web sites are now multi-language Web sites, the common layout for these Web sites is to separate the languages to separate pages. This commonality is reflected in the standards on localization (LISA, 2008.). This localization can be found in e-government. Cunliffe et al (2002) reports a case study of developing a bilingual Web site in English and Welsh for users in Wales. This study focused on Web site design for just two languages and recognized that there are many bilingual areas in the world (Cunliffe et al, 2002). One of the most important aspects of designing for bilingual Web site content is to provide rich interconnectivity between materials in the two languages (Cunliffe et al, 2002). While not the main focus of the study, Cunliffe, et al. (2002) does discuss the options for placement of two languages on the same page.

Paralingual Web design is expected to affect e-government use two ways: increased use due to increased trust and possible decrease in use due to impacts on ease of use and usefulness. As

Figure 1. Technology acceptance model (Davis, 1989)



discussed above it is expected to help improve trust. The two models mentioned in the Introduction help to predict the probable impact of paralingual Web design. TAM was developed by Davis (1989) as an explanation of the general case determinants of computer acceptance that are capable of explaining user behavior across a broad range of systems, technologies, and user populations. The model includes use as a determinant but indicates that use is determined by ease of use and perceived usefulness, attitude, and intention to use (see Figure 1). TAM is a derivative of Fishbein and Ajzen's (1975) Theory of Reasoned Action (TRA) model. TRA focuses on situation specific personal beliefs and attitudes, and the effects of the beliefs of others who can influence the individual. The fundamental premise of TRA is that individuals will adopt a specific behavior if they perceive it will lead to positive outcomes (Compeau and Higgins, 2001). However, adoption is also influenced by two factors, Perceived Usefulness and Perceived Ease of Use. Perceived Usefulness reflects that an individual's perception of usefulness influences their intention to use the technology primarily through the creation of a positive attitude. This is consistent with the TRA, which holds that attitude (an individual's positive or negative feelings about performing a behavior) influence behavioral intention. Geffen, et al. (2002) found that trust impacts Perceived Usefulness with increased trust improving Perceived Usefulness. Perceived Ease of Use reflects the user's assessment of how easy a system is to learn and use. TAM includes ease of use as a separate belief construct based on the concept of self-efficacy (an individual's judgment of his/her ability to organize and execute tasks necessary to perform a behavior). Ultimately, TAM predicts that if paralingual Web design can improve trust with the users while not reducing perceptions of ease of use or usefulness then it can be expected that paralingual Web design will be accepted by users.

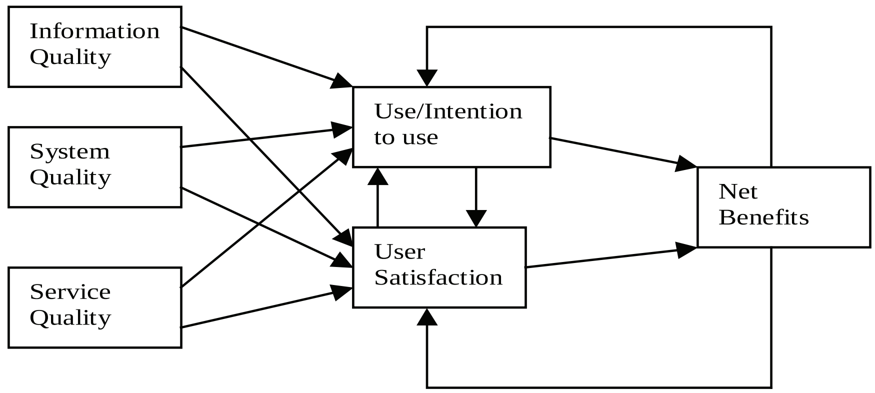
DeLone and McLean (2003) revision of the IS Success Model also helps predict the impact of paralingual Web design. This is a causation model that implies that system quality, information quality, and service quality will lead to increased use or increased intent to use which will lead to benefits and success of the system (see Figure 2.) The intent to use construct is important for this article as it is similar to the ease of use and usefulness constructs from TAM, especially when intent to use is operationalized using the Perceived Benefit Model (Thompson, Higgins, and Howell, 1991). Additionally, trust is reflected in the information quality dimension as users must be able to trust the information in the system for there to be quality. Paralingual Web design provides the trust in the information quality and aids in perceived usefulness in intent to use. Ultimately, the IS Success Model predicts that improved trust will help improve information quality which will increase intent to use/actual use leading to benefits and system success.

The conclusion from the literature review is that Paralingual Web design may be a design tool that will support building trust in content and process by e-government users. As mentioned earlier, Geffen, et al. (2002) consider this essential for e-government adoption as it support perceived usefulness. The only concern is an impact to perceived ease of use resulting in the experiment design discussed in the next section.

RESEARCH METHODOLOGY

This study sought to determine whether paralingual Web site design can improve trust in e-government Web sites while maintaining ease of use and usefulness for both the reader and the provider government. In a bi or multilingual environment, the ability to communicate concepts across diverse cultures and languages has become increasingly important, especially when issues of trust are involved. Further, e-government has

Figure 2. DeLone and McLean's (2003) Revisited IS success model



rapidly increased in usage, making it even more essential for Web designers to conscientiously strive to ensure that concepts have the same meaning across cultures. This study focuses on paralingaul issues in a highly bilingual populated location in the United States, that of San Diego and Tijuana, with a total combined population of over 5 million as of 2004 and over 64 million annual border crossings. The subject municipality is National City, a city of 54,260 (2000 census) located approximately 10 miles from the United States border with Mexico. The municipality population is 60% Hispanic/Latino (all or part), 39% white (all or part), and 30% other (all or part where other includes Asian, Hawaiian/Pacific Islander, Black, and American Indian) (Note that the sum is greater than 100% due to respondents reporting belonging to more than one race) (National City, 2008). Actual percentage of English-Spanish bilingual residents is not reported but is understood to be large. The subject municipality was selected because of its expected bilingual population and its willingness to participate in the experiment. It should be noted that simply because the municipality population is heavily Hispanic or Latino does not mean that the local language is predominately Spanish. This is a US city and the citizens are US citizens. English is the majority language spoken in National City as evidenced by the National City Web site being in English only. However, due to its proximity to the border and its large Hispanic/Latino population it is reasonable to assume there is a substantial bilingual population.

To create the experiment, three informational Web pages were converted to paralingual format consisting of English and Spanish text placed horizontally adjacent to each other. Informational pages were chosen as the National City Web site is primarily informational and does not perform any financial transactions. This is considered acceptable as the majority of e-government Web sites in 2004 were informational rather than financial transaction focused (ICMA, 2004). Translation of the English content in the original selected Web pages was performed taking into account the following:

- Variations in the style and vocabulary of Spanish. A style to reflect the local style was chosen. This style is mostly Mexican in its structure and vocabulary, so these were kept in perspective at all times.
- The level of writing was kept at approximately a high school level of comprehension (the same as the English version).
- The Spanish translation was written to conform strictly to correct language structure, syntax, and spelling. This is demonstrated by the correct application of diacritical marks, such as accents, tildes, and umlauts.

The translation task was performed by a native Spanish speaker with professional training and experience as a translator. The translated content was then evaluated and modified by a Spanish language professor with a specialization in translation studies.

A survey was generated using survey monkey to gauge the opinions of visitors to the experimental Web pages. The survey consisted of eight items. Items 1-4 dealt with demographics of the respondents and were asked at the request of National City:

1. What is your age range? (18-24, 25-34, 35-44, 45-54, 55-64, 65 or over)
2. Are you a resident of National City? (Yes, No)
3. What language or languages do you use for communication (speaking, reading, writing)? (English only, Spanish only, mostly English with some Spanish, about half English and half Spanish, mostly Spanish with some English, some other combination of languages) (Note that this question was used to group responses)
4. Have you visited the National City official Web site before now? (Yes, No)

Items 5 and 6 operationalized trust. Item 5 queries improved trust due to the information on the Web page while item 6 queries improved trust due to the paralingual format. Two items were used to ensure that improvement in trust was due to paralingual format and not to just reading the information (both use a 7 point Likert scale with 1 being Strongly Disagree and 7 being Strongly Agree):

5. Please respond to this statement: I have a greater trust now than before in my understanding of the National City Web site.
6. Please respond to this statement: I have a greater trust now than before in the information on the National City Web site because it is in English and Spanish side by side.

The seventh item was also asked at the request of National City and queried how aware the respondent was of the multilingual nature of National City:

7. Are you aware that other residents in National City speak more than one language? (Yes, No, Not sure)

The final item operationalized ease of use and usefulness by querying perceptions of site readability. Only readability is measured as no transactions are performed with the paralingual Web sites:

8. Please respond to this statement: It was easy for me to read the pages with English and Spanish next to each other: (No, it was very difficult, No, it was somewhat difficult, It was neither difficult nor easy, Yes, it was somewhat easy, Yes, it was very easy)

Municipality officials encouraged participation by constituents and residents in the vicinity through a series of bilingual public announcements encouraging individuals to visit the modified Web pages and to complete a brief survey documenting their opinions on the Web site. The respondents to the survey had the choice of filling out the survey in English or Spanish, presumably selecting their primary language of communication. The respondents who answered the online surveys represent a portion of Web users who visited the National City Web site and chose to view at least one of the paralingual pages. This constitutes a self-selected sample. The visitors to the Web site may have been responding to one of the various methods of advertisement of the research, or may have been incidental visitors to the Web site who then decided to follow a link from the home page to one of the paralingual pages. While there are problems with self selected samples, it is acceptable for this experiment as the goal was to get real users to respond to the Web pages and the inherent difficulties in recruiting a random sample on a public Web page. Data was collected over a three month period with 133 responses being collected. Data were grouped based on the respondent's answer to the question asked about the respondent's primary language for communication. The range of response choices was from "English only" to "Spanish only"; an additional choice was "some other combination of languages." In order to generate analytical results that are more representative of the language component of the sample data, the English sample data included only those who indicated "English only," "Mostly English," or "some other combination of languages." The Spanish sample data included those that indicated "Spanish only," "mostly Spanish," or "half English and half Spanish." This resulted in 97 English responses and 36 Spanish responses.

Statistical data analysis was used to analyze the collected data. Beatty (2000), Siegel (1956), McClave, Benson, and Sincich (2008), Jaccard and Becker (1990), and others have stressed the importance of selecting appropriate statistical procedures that correspond to the methods used to assign numerical values, as well as the type and level of data being analyzed. Since the questionnaires employed in the current study are based on a traditional Likert format, with anchor points ranging from "strongly disagree" to "strongly agree," nonparametric statistics were deemed appropriate. The nonparametric tools used include the Mann-Whitney U test, the Wilcoxon T test, and Spearman's rho. The Mann-Whitney U test is an appropriate tool for comparing central tendencies between *independent* responses to Question 5 and 6 *across* the two language groups, while the Wilcoxon matched pairs T test is an appropriate tool for comparing central tendencies across the *matched* pairs of data. With regard to tests of association, Spearman's rho is an appropriate measure for examining the correlation between matched responses to Questions 5 and 6 *within* each language group. When deemed appropriate and meaningful, means and standard deviations have been calculated for various data sets as well. All statistical tests were performed via SPSS and validated using other software. All results are reported in the format recommended by Jaccard and Becker (1990).

All collected surveys were used for the analysis. There was no exclusion or limitation of surveys based on any criteria. However, it should be noted that some respondents did not fill out all survey questions. For example, a small portion of both English and Spanish respondents did not fill out the second half of the surveys. Thus, the data used in different components of the analysis consist of different sample sizes, depending on the questions being examined. The software used for these analytical tests accounted for the missing data and thus calculated test values based only on the number of questions actually answered.

RESULTS AND DISCUSSION

For all tests, the alpha value was chosen to be $\alpha = 0.05$. For ease and uniformity of comparison between all tests, the z value will be used. For the chosen $\alpha = 0.05$ and 2-tailed tests, the critical z value is $z = \pm 1.96$.

Mann-Whitney U on Grouping by Language Choice

The Mann-Whitney U test was used to compare the central tendencies of responses to item 5: I have a greater trust now than before in my understanding of the National City Web site, based on the 97 English-based responses and the 36 Spanish-based responses. This item was designed to measure differences between respondents' improvement of trust in their *understanding* of the information on the paralingual page only. The Mann-Whitney

U and its corresponding *z*-value (-1.907) resulted in no statistical difference in perceptions between the English and Spanish respondents.

A second Mann-Whitney U test was used to compare the central tendencies of responses to item 6: I have a greater trust now than before in the information on the National City Web site because it is in English and Spanish side by side, again based on the 97 English-based responses and the 36 Spanish-based responses. This item was designed to measure differences between the respondents' improvement of trust in regard to the *information* on the paralingual page, based on having the information in the two languages on the same page. This test yielded a *z*-value of -4.406 ($p < .01$), indicating that there were significant differences between the responses of the English and Spanish respondents with regard to this question.

These results partially support the hypothesis that use of paralingual Web pages will increase trust in the page content and government sponsor. Since trust levels are different only when the paralingual information is considered, and the Spanish respondents showed higher medians than the English respondents in both items 5 and 6, the Spanish respondents show an increased level of trust based on the paralingual content.

Wilcoxon T Test on Grouping by Language Choice

The Wilcoxon matched-pairs T test was used to compare the central tendencies on data sets similar to those tested with the Mann-Whitney U test, items 5 and 6. The calculated z value for English items 5 and 6 is $z = -3.188$. This indicates that there is a statistical difference in the means of the answers to each item. For Spanish items 5 and 6, the calculated z value is $z = -1.034$ and we fail to reject the null hypothesis, therefore we conclude that there is no statistical difference in the means of the answers to each item.

This result seems to indicate that Spanish speakers improved their trust because the text was in Spanish, this does not necessarily support that a paralingual Web design is necessary to improve trust and that simply being bi-lingual in some format will increase trust of the minority speakers.

Spearman's rho on Grouping by Language Choice

Spearman's rho was used to examine the relationship between responses on English item 5 (n=97) and 6 (n=97) to determine how well the English respondents' answers correlated between the two items regarding trust. The test measures the level of correlation between these two items. The two-tailed test yielded $\rho = 0.504$ ($p < .01$), which was statistically significant.

Spearman's rho was also calculated for Spanish items 5 (n=36) and 6 (n=36). The calculated correlation, $\rho = 0.563$ ($p<.01$), is significant for a 2-tailed test as calculated by SPSS.

Spearman's rho was performed to see the degree of correlation between items 5 and 6 in each group. The rho value for English items 5 and 6 is 0.504, so the correlation is "significant". For Spanish items 5 and 6 the rho value is 0.563, also significant. Thus each of the two groups answered consistently in the trust questions.

Readability Reflecting Ease of Use and Usefulness of the Paralingual Web Pages

Item 8 of the survey is a measure of the readability as reflecting ease of use and usefulness of the paralingual pages. The choices for responses had a range of five from "it was very difficult" to "it was very easy." The percentages of the English respondents (n=97) who answered "it was somewhat easy" or "it was very easy" is 61.3 % and the percentage of Spanish respondents (n=36) answering similarly is 85.7%. This is interpreted to imply that having the page in paralingual format did not diminish readability and thus ease of use and usefulness, important to predicting acceptance of paralingual Web pages by users. However, it is also implied that English respondents were more likely to find an impact to ease of use and usefulness. This may suggest that these respondents will be less accepting of a change to paralingual format as they perceive paralingual format to be less useful.

Alternative Analytical Calculations

Performing nonparametric tests is the appropriate method for analysis of ordinal data. These results have been shown in the previous section. However, means and standard deviations are more commonly understood and therefore used more commonly to describe data. Table 1 is a summary of the means and standard deviations for items 5, 6, and 8.

CONCLUSION

This article is primarily intended to provide evidence to support government decision makers, e-government researchers, and e-government Web designers in applying paralingual Web page design for improving trust in government in regions where there is a high proportion of bilingual residents. An experiment was performed to test the hypothesis that paralingual Web design will improve trust in the content of the e-government Web page without significantly affecting ease of use and usefulness. This hypothesis was confirmed, but not quite as expected. It was found that the paralingual format improved trust for the minority speaker but not the majority speaker. Upon reflection this is an expected finding.

An additional finding with respect to ease of use and usefulness was noted. It was found that in general respondents did not find the paralingual format hard to read, however, it was noted that the majority speakers (English) were less enthusiastic than the minority (Spanish) speakers about the paralingual Web design. This finding has implications for the adoption of paralingual Web design in that it may show that there will be resistance to adoption of a paralingual Web approach by the majority speakers. The implication to policy makers is that there needs to be additional research done with respect of citizen attitudes towards bilingual government prior to implementing a paralingual Web strategy. This is particularly important in different regions of the United States where it could be expected that the generally favorable bilingual acceptance attitudes found in California may not exist.

The conclusion of this article is that paralingual Web design is useful for e-government in areas with significant bilingual populations. However, there are limitations to this approach as it appears that there is a risk of backlash and rejection from the majority speaking population. The implication for policy makers is that paralingual Web design should be used when there are known trust issues between majority and minority speakers that translate into trust issues with government and e-government initiatives.

Table 1. Means and standard deviations of survey data

Item	Value Range	English: Mean/StdDev	Spanish: Mean/StdDev
5	1 - 7	4.2209/1.785	4.8182/1.286
6	1 - 7	3.5930/1.811	5.0606/1.540
8	1 - 5	3.88/1.259	4.366/0.994

Limitations

This experiment has a small sample with limited items testing improved trust and ease of use and usefulness. The conclusion that paralingual Web design improved trust for the minority Spanish speakers is supported by the statistical analysis but it cannot be totally discounted that trust may have been increased simply because the content was in Spanish. Additionally, this experiment only looked at informational Web pages and the conclusions may not apply to financial or other transactional Web pages. Finally, only one city was looked at, one minority language used (Spanish,) and the sample population was self selected meaning that the results may not be reflective of all populations, cultures, and languages.

Areas for Future Research

There are several areas for future research of which the first are those areas that address the limitations to this research. This includes further studies using other languages and locations; obtaining a large sample size; and using transaction based Web pages in addition to informational pages. It is expected that there may be ease of use and usefulness issues associated with paralingual Web design used for transactional Web pages which could affect adoption of the pages and requiring that the trust improvement from paralingual Web design be balanced against ease of use and usefulness.

An additional area for future research is in using paralingual Web design in a multilingual environment. In this case multilingual implies more than two languages and is a topic of relevance in many countries in Europe and Asia (Finland and Switzerland are two examples). While there are historical examples of multilingual designs, none are in Web page layouts (the Rosetta Stone is an example of a three language representation). Given the limitations on screen areas, especially for mobile and/or handheld devices, a paralingual Web design involving three or more languages may not be practical or may induce substantial ease of use and usefulness issues. Research needs to be done to see if this is a practical approach or if more traditional approaches of having multiple versions of the same Web page each in a different language is a preferable approach.

A final area for future research is in e-government policy. The conclusion that majority speakers may resist paralingual implementations is very important to policy makers. Research into what factors may influence majority speakers to accept and adopt paralingual implementations or which factors may influence majority speakers to reject paralingual implementations is critical to policy makers for crafting appropriate e-government strategies and policies. It is expected that paralingual Web design will only be appropriate in regions where there is significant lack of trust by the minority speakers but this needs to be confirmed.

Chapter 2.3
Designing Medical Research Web Sites

Jonathan P. Grady
University of Pittsburgh, USA

Michael B. Spring
University of Pittsburgh, USA

Armando J. Rotondi
University of Pittsburgh, USA

ABSTRACT

This chapter discusses the design of Web sites to be used as the basis of medical research. It is broken down into three sections: Part 1 discusses the various issues that have to be addressed in the design of a Web site that will be used to assess some intervention based on the Web site. Part 2 discusses the design of such a Web site and the development of a tool to facilitate this process. Part 3 presents the results of preliminary usability analysis for the tool to assist medical researchers in constructing Web sites that can meet the needs and requirements of medical intervention studies. The results of the preliminary interviews, prototype walkthroughs, and preliminary usability studies are presented laying the groundwork for future development and more formal usability studies.

DOI: 10.4018/978-1-60566-356-2.ch053

INTRODUCTION

The Internet, specifically the World Wide Web, is being tested by the medical community as a potentially more efficient and effective mechanism to serve the needs of patients and caregivers. The Web can be used to quickly and cost-effectively disseminate information, collect data and target communications to specific people or groups of people. May et al., (2005) describe a range of efforts in the United Kingdom to provide services via telemedicine. In the United States, researchers have begun to study the efficacy of web-based medical interventions. Studies have been performed in recent years examining the effectiveness of internet-based interventions with patients suffering from a variety of medical conditions, including heart transplants (Dew et al., 2004), smoking cessation (Lenert et al., 2003), osteoarthritis (McAlindon, Formica, Kabbara, LaValley, & Lehmer, 2003), clinical depression (Christensen, Griffiths, & Jorm, 2004), *traumatic brain injury (*Rotondi, Sinkule, & Spring, 2005), and schizophrenia (Rotondi et al., 2007). While these studies had different degrees of success achieving their goals, they generally concluded that 1) the Internet is a potentially useful tool for medical interventions, and 2) the success of an Internet-delivered treatment depends largely on the design of the website and other electronic communications used in conjunction with the treatment.

The cost to design, implement and maintain a website to be used as the basis for medical intervention research can be high. Projects at the University of Pittsburgh by Rotondi and Spring budgeted equipment, staff and maintenance costs for a medical research website well in excess of $100,000. Marshall and Haley (2000) report the cost of setting up the site infrastructure alone at $35,000. Mounting a website for medical research takes from three months to a year, depending on the amount of usability testing that needs to be done. At the same time, an under-budgeted or poorly designed website can result in sub-optimal usability for subjects, data that cannot be used to answer research questions, exposure of sensitive patient data, etc. Poorly designed research websites are created because:

- The medical researcher does not understand the nature of website design. (A researcher may not anticipate the need to translate their professional model of the subject matter into a model manageable by the consumer.)
- The individual or team hired to design the website may not have knowledge about the nature of the subjects or the treatment. (The designer may not be aware of physical or cognitive impairments that will require simplified navigational systems or reduced page complexity.)
- Medical researchers may not understand the capabilities or the limitations of data gathering related to the website and designers may not be aware of the data analysis needs of the intervention. For example, how will session information be maintained, how will IDs be assigned, and how will treatment groups be identified?
- The designers may not have sufficient knowledge of the Health Insurance Portability and Accountability Act of 1996 (HIPAA) which sets rigorous standards for protecting patients' personal information (Neale & Schwartz, 2004); data collection, storage, and sharing mechanisms must be carefully designed to adhere to these standards.

Websites used in a variety of interventions reported in the literature had many common elements. This suggested that it might be possible to develop tools to aid the development of reliable and functional medical intervention websites at lower cost. With this in mind, we set out to develop a system that would:

1. Eliminate common pitfalls in design
2. Enhance data collection to better meet research objectives.
3. Reduce cost.
4. Ensure that the website is maximally usable by the target population.
5. Ensures that the website is as secure as possible.

The effectiveness of a system can be assessed based on:

1. Time required to build a website.
2. Monetary cost of building a website.
3. Ability to meet HIPAA requirements for security and privacy of medical data.
4. Usability of the website from both the end-users' and researchers' perspectives.

The rest of the chapter is structured as follows. First, we describe the needs of web-based medical interventions, as well as HIPAA and its implications for medical websites. This section also provides a survey of recent efforts to standardize the collection and presentation of medical information. Second, we present the framework for designing Internet-based interventions based on the critical characteristics identified from recent literature and introduce Webmaster-R (Webmaster for Research), a system built around the framework that is designed to augment a researcher's ability to mount a medical intervention website. Third, we present some formative evaluation data related to the efficacy of the Webmaster-R system using a heuristic evaluation and walkthrough with researchers from the University of Pittsburgh's School of Medicine. The last section discusses directions for future work.

BACKGROUND

Bush et al. (2004) proposed a framework for Internet and Web access that medical researchers should consider when designing an online study. The authors divided these issues into two groups, connectivity and human interface. *Connectivity* encompassed all issues related to the capabilities of the hardware and software used in conjunction with Internet access, as well as the availability of access based on geography, locale, and degree of convenience. *Human interface* involved all issues related to demographics, skill sets, and special needs of potential participants. Bush et al. then applied the highly detailed framework to the recruitment of subjects for a pilot study communicating breast cancer risk. Marshall and Haley (2000) presented a ten-step process for building a secure website for collaborative research from the ground up. The authors focused on the site's database, including 1) developing the database schema, 2) selecting a DBMS package, and 3) creating a separate table of variables for each investigator. Next, the authors 4) designed the screen layouts of each Web page, 5) selected a middleware product for connecting the site's pages to the DBMS, and 6) coded the pages, using JavaScript validation code on each page to verify user input. After completing the database and website, the authors 7) set up a machine to house both the database and web server software, 8) obtained a unique IP address and domain name, 9) applied security measures to the infrastructure, and 10) trained the staff who will enter data. The authors provided a detailed outline of suggested security practices, including security procedures for the website, servers, client machines, and facilities housing the servers.

Spring and Rotondi at the University of Pittsburgh collaborated on the development of several sites to support research on internet-based medical interventions. This chapter is in part a report of a series of interviews conducted in July, 2005 with Spring, Rotondi, and other researchers involved in the early stages of website development to gather a preliminary list of needs. The list of critical needs generated from these interviews included:

- Navigation and design elements appropriate for audience
- Methods to ensure information is presented at the right level of detail for the intended audience.
- Tools to optimize data collection and analysis.
- Naming conventions for various elements of an internet-based intervention, including the usernames of participants and the names of web pages.
- Ability to segment participants and isolate interactions based upon these segments.
- The site developed complies with HIPAA guidelines.

Based upon this input, a prototype system was developed, whose design and preliminary evaluations are explained in greater detail in Sections 3 and 4 respectively.

Figure 1. Comparison of the identified types of medical websites

	Medical Information	**Medical Intervention**	**Medical Intervention Research**
Objective	Provide general information on medical conditions; match potential patients with physicians	Provide treatment and mechanisms to help consumers cope with their condition; improve well-being	Collect data and test hypotheses for research while providing treatment to consumers
Access	Public	Private	Private
Bound by HIPAA?	No	Yes	Yes
Subject to IRB Review?	No	No	Yes
Data Analysis Needs	No	Minimal	Significant

A Website Taxonomy

Websites serve different purposes. We classify sites generally as 1) providing information, 2) supporting interaction, 3) allowing transactions, 4) supporting transformation. Generally, the evolution of a website moves from information only to one that provides the first three functions. The last stage of website evolution is one where it transforms the nature of the service or business. For example, in phase 3, the web provides an alternative mechanism for transactions. In phase 4, new services may be provided which are not possible in non-web formats. Our work here is primarily directed to sites that provide for information and interaction, with some minimal consideration of transactions. The use of websites to transform how medical interventions are delivered is likely to come about only after significant research data has been collected on the efficacy of parallel interventions.

We further classify medical websites in terms or whether they are intended to support: 1) general information dissemination, 2) patient interventions, or 3) research on interventions. Figure 1 summarizes a few of the differences. The nature of the types of sites is described below.

Information Websites

Medical information websites provide information on one or more medical conditions. No relationship with a physician is assumed. Because these websites do not provide any treatment, they are not bound by HIPAA guidelines. If discussion groups and chat rooms are publicly accessible, users are informed that their postings are not private. One of the largest and well-known medical information websites is WebMD's Consumer Portal (http://www.webmd.com), which provides public access to treatment information, discussion boards, and expert chats concerning a wide variety of medical conditions, all targeted to a general audience.

Medical Intervention Websites

Medical intervention websites are designed for physicians to provide information and/or treatment to specific consumers who have specific medical conditions. While the information provided on medical intervention websites may be similar to medical information sites, it is targeted at specific individuals and may contain references to an individual's specific condition. Thus, measures are taken to ensure that interactions among site users remain secure and private. Because client-physician relationships are established, medical intervention websites must adhere to HIPAA guidelines. Therefore, these sites tend to serve a much smaller audience whose members must be granted access to the sites resources explicitly. Interactions on the site (e.g., discussion groups) are monitored and accessible only to group members and authorized individuals. Data collected from the website must be secured, and all personally identifiable information eliminated from general exposure.

Medical Intervention Research Websites

Similar in structure to medical intervention websites, *medical intervention research websites* are specifically designed for collecting data on client interaction as clinical trials are conducted through the website. Medical intervention research websites share the same characteristics of medical intervention websites, but also include features – such as log and data analysis tools - to aid researchers in the analysis of the efficacy of the intervention. The studies cited in the next section all employed secured, private medical intervention research websites available only to specific audiences dealing with specific medical conditions.

Common Characteristics of Medical Intervention Websites

Many of the early Web-based medical interventions use the web to deliver treatment and provide guidance to patients, family members and the caregivers of those suffering from a medical condition. These interventions have become more feasible over the last 10 years as the penetration of Internet connectivity in U.S. households has increased. There is increasing support for the use of the web for a wide range of treatments (Ikemba et al, 2002.) Our work on intervention websites has focused on two common functions:

Information Dissemination

The websites include a repository of condition-specific medical information designed for patients and their families, as well as links to selected external resources. Presenting the information at an appropriate level with the right amount of detail was found to be especially critical. Rotondi et al. (2007) used a concrete, text-rich design with a shallow navigation structure that has been found to be more appropriate for those suffering from cognitive impairments, such as schizophrenia. Christensen et al., (2004) included a depression literacy website designed with an eighth-grade reading level. Lenert et al. (2003) attributed the high drop-out rate in their multi-stage smoking cessation program to relevant medical information being presented at an inappropriate level of detail (namely confusing navigation structure and text-heavy design).

Communication Mechanisms

Communication between individuals and professionals is an important aspect of many research intervention studies. The public intervention websites (e.g., WebMD and Schizophrenia.com) provide public discussion boards for individuals to share experiences related to the medical condition or topic. The research-oriented intervention websites included a mechanism for doctors to send messages to groups of patients, and most included a hyperlink or contact form for individual patients to send messages to doctors. Gray et al. (2000) included monitored discussion boards for interaction among patient families, as well as video conferencing capabilities for real-time communication between families and medical staff members. Communication was not anonymous in the discussion groups, but privacy of communication was paramount in doctor-family interactions. Because the site fostered a great deal of support among families and caregivers, the Internet-based intervention was well-received. Lenert et al.'s (2003) smoking cessation intervention had limited interaction capabilities, other than doctor-patient and site-patient communication via email, which may have also led to the program's high dropout rate.

HIPAA Concerns

The Health Information Portability and Accountability Act (HIPAA), which took full effect in 2003, specifies procedures for handling the personally identifiable information (PII) of patients in a secure, private, and confidential manner. HIPAA places restrictions on the PII that can be collected, stored, and transmitted via websites and email communications. The Act also requires organizations to disclose their procedures for handling PII in their privacy policies. While many organizations have updated their privacy policies to meet new guidelines, a recent study found the new policies have actually become harder to read and understand (Anton et al., 2007.) Given the ramifications of HIPAA's guidelines, as well as the long-existing needs to preserve patient confidentiality and the integrity of research experiments, a number of recent studies have focused on privacy and security implementations within the context of Internet-based interventions.

Schmidt (2003) examined HIPAA's implications on the privacy and security of electronic patient-physician communications. The original text of the HIPAA Security Rule required all email communications between patients and physicians to be encrypted. Because no universal solution for email encryption exists, this rule would have significantly discouraged the use of email by both patients and doctors, impeding communication between the two. The current text of the Rule now states that email encryption should be performed if it is feasible, but allows organizations to address alternative methods. Schmidt advocates examination of security measures (ex. PGP, Web-based Encryption) to avoid accidental disclosure but suggests having patients authorize the use of unencrypted email.

Baer, Sariou, and Koutsky (2002) provided a detailed explanation of their data collection and storage methods of sensitive health information from university students. Men and women were assigned access to different URL's, where all communication (including login) was encrypted using SSL 3.0. All form data provided by subjects were validated using a JavaScript-based validator before being posted. Validated data were encrypted using PGP v.2.6.2 and then written to the server in text files. Only authorized administrators decrypted the data in the text file, using a separate computer disconnected from all networks.

The need for website authentication and access controls was critical to the integrity of experiments, especially when identifying the subjects of experimental groups using the website during trials, and making sure only they were the ones using the website. McAlindon et al. (2003), while using their website to also recruit potential subjects for their osteoarthritis trials, used offline consent forms and medical records to authenticate subjects before accepting them into the study. Gray et al.'s (2000) Internet-based intervention for high-risk infants utilized RSA's SecureID handheld device, allowing users to log in to the website with a one-time hash generated from the device along with their memorized PIN.

FRAMEWORK FOR MEDICAL INTERVENTION RESEARCH WEBSITES

The frameworks suggested by Bush et al. (2004) and Marshall and Haley (2000) provide reasonable starting points for medical intervention researchers. However, these solutions require a significant working relationship between researchers and web designers. As Rotondi and Spring reported in interviews, the cost of this kind of web site development and maintenance exceeded $200,000 in their studies. Examination of the frameworks suggests that the difficult problems exist in three areas: infrastructure, site development, and data analysis. There are interrelations among these three areas, but they can to some extent be treated separately. The area of greatest cost variance, and the area most amenable to automation is the second – site development. The primary focus of our work has been on addressing this second area by developing a tool called Webmaster-R (Webmaster for Research). While the tool is conceptually similar to generalized tools such as Dreamweaver and FrontPage, the tool is also designed to insure that the site meets the requirements for security and privacy of medical data as outlined in the Health Insurance Portability and Accountability Act, meets the needs of the researchers for ease of construction and maintenance, and insures that data is appropriately collected and organized for research study data analysis. This work has been funded in part by the Dean of the School of Information Sciences at the University of Pittsburgh. Below we discuss some of the infrastructure considerations, which are generally outside the scope of the current work. Next, we introduce the website development framework considerations. Finally, we examine some of the data analysis considerations, which are not yet addressed, but which are within the scope of this research.

Infrastructure

Infrastructure includes the hardware running the intervention website, as well as the facilities and network supporting the site. With the risks of privacy, security, and confidentiality breaches of patient data, setting up a properly-designed and robust infrastructure requires careful consideration. Infrastructure concerns include:

- **Physical Facilities:** Equipment should be housed in locked rooms with access limited to a small number of people. Servers should be connected to uninterruptible power supplies with surge protection to prevent loss of data and minimize server outages.
- **Network:** The bandwidth and Quality-of-Service(QoS) needs of a medical intervention website will vary depending upon the web components, the number of users accessing the site, frequency of access, and the amount of data transmitted per visit. Employing a bandwidth-intensive component such as video conferencing, as Gray et al. (2000) did in their high-risk infant study, makes Quality-of-Service a potentially critical aspect of a medical intervention website. Service disruptions may cause undue anxiety to the patients (or caregivers), diminishing the effectiveness of the intervention and suggesting the need for redundant servers, disks, and network access points.
- **General Server Security:** The number of users with access to the data on the server should be kept to a minimum. Default passwords should be changed to ones that cannot be easily guessed or discovered using brute-force attacks. Anti-virus, firewall, and intrusion detection software should be installed and configured to run automatically. All unnecessary network services (ex. Telnet, FTP, IRC) should be disabled.

Network connections to the server for purposes of development should be restricted to authorized domains.

- **Logging, auditing:** Auditing and log analysis is critical in determining not only who is accessing the site, but also in providing statistics on how often subjects are visiting the site and what activities they engage in during their visits. Logging was important in Lenert et al.'s (2003) smoking cessation intervention for determining how far subjects progressed in the multi-stage program before quitting the trial, as those subjects most often did not respond to e-mail follow-ups. When assigning user logins, employ naming conventions that make identifying different categories of authorized users in the log files easier.
- **Backup procedure:** Data critical to the intervention – database tables, web pages, and site structures – should be backed up each night on tape media. RAID redundancy should be employed to prevent loss of data in case of a fatal hard drive failure. All backup procedures should be documented.
- **Web and DBMS servers:** All pages, including the root page of the website, should be accessed only through authenticated login, ideally using SSL encryption (thus requiring a certificate issued from a certificate authority such as VeriSign or Thawte.) The URL of the research website should be advertised only to authorized users. Permissions should be set on directories and/or specific pages to prevent access from unauthorized users within the research study (e.g., to prevent participants from gaining access to administrative pages.) Security procedures should be documented, and staff members should be trained on website security techniques.

While this chapter focuses on the development of the website itself, the following checklist provides an indication of the complex issues that a medical researcher should insure are being addressed by those responsible for installation and management of the infrastructure.

Related to the Operating System (assuming Microsoft Windows):

- Apply all security patches before connection to the Internet, from a CD or other removable media.
- Do NOT set up the server as part of a Windows domain.
- Set the administrator password to at least 8 characters in length.
- Use a password that is difficult to guess, not based on a dictionary word, using a mixture of numerical, upper and lower case characters.
- Create separate logins for each user, and give them access only to the resources they need.
- Install anti-virus software (such as Symantec Anti-Virus).
- Set the Windows Firewall to "on".
- Obtain (for free) Microsoft's Baseline Security Analyzer for routine security checks.
- Check event and system logs on a regular basis (daily or weekly).
- Set Windows Automatic Updates to notify you when patches are available, download them, but NOT to install them. Verify and only then install them.

Related to the Web Server (assuming Microsoft IIS):

- Turn on only those services (e.g.. FTP, mail) that you need.

° If using IIS 5.0, turn off all unnecessary services.

° If using IIS 6.0, check that all other services are turned off (by default, they should be.)

- Ensure logging is enabled

- Ensure that Directory Traversal is turned OFF.
- Disable Internet Printing
- Give write privileges only to administrators or other users authorized to edit the content of the website.

Securing Your Database Server (assuming Microsoft SQL Server):

- Run the database server under an account without administrator privileges
- Assign a password to the "sa" account.
- Do NOT allow direct connections to the database server.
- Devise a backup plan for all databases
- Do NOT grant full access to your databases to all users. Limit users' access to only those resources that they need.
- Ensure that all scripts and code programmed by developers are secure.

° Verify input data types (ISNUMERIC)

° For string data, replace single quotes with two single quotes

° Create reusable input validation modules

° Use stored procedures to abstract data access.

This is only a sample list. More definitive and up-to-date lists can be obtained by your organizational security offices or from organizations such as CERT (http://www.cert.org/).

Website Design Principles

As with websites generally, the components of the website can be classified into four categories: 1) *information*, referring to the medical content and related resources of the site, as well as any means of searching, indexing, or managing the site's content and resources; 2) *interaction*, which describes person-to-person communication facilitated by the website, 3) *transaction*, which refers to any medical treatment performed via electronic communication (ex. medical diagnosis, testing, prescriptions), and 4) *transformation*, which refers to unique services available only through web services. We examine the nature of the first three below.

Information components provide access to the medical content and related web resources located internally or externally, as well as any means of searching, indexing, or managing the site's content and resources. The presentation of information should center on the characteristics and needs of the target audience. Information should be presented at the appropriate level and appropriate detail for the understanding of the intended audience, and mechanisms should be put in place to ensure the appropriateness of the content (ex. checking reading level). Navigation structures should coincide with a user's mental model of the presented information. Mechanisms should be provided for collaborating researchers to insert and review resources. Resources should be indexed with search capabilities, so users can easily locate relevant material. Other Web resources, such as documents on external websites, should be included only if they are relevant to the treatment.

Interaction entails any aspect of person-to-person or person-to-group communication facilitated by the website. In a medical intervention environment, interactions can have many distinct forms: Doctor-site, Patient-doctor, Caregiver-doctor, Caregiver-patient, and Patient-patient. Doctor-site interaction refers to "broadcast" communications that are posted by a medical researcher onto the website, such as responses to questions or event announcements, targeted to the general audience. The remaining interactions, however, are all individual-individual, and require special consideration in terms of HIPAA compliance and confidentiality:

- **Isolation of discussions:** Create separate chats or discussion boards, granting permissions only to members of specific groups to facilitate treatment and preserve patient confidentiality.

- **Privacy of communications:** Interactions should only be disclosed either according to the site's privacy policy, or by explicit consent of the patient or caregiver. Mechanisms should be put in place (such as options on an HTML form) that allow participants to control disclosure of their communications.
- **Anonymity of communication:** According to HIPAA guidelines, virtually all personally identifiable information (PII) must be stripped from communication. When possible, data collection tools should be set up to exclude PII and only use usernames, making identifying individuals difficult should information be disclosed unintentionally.
- **Real-time communication:** IRC and video-conferencing capabilities should be included if synchronous communication is required as part of the intervention.

Other elements of communication that require modifications to infrastructure procedures should also be considered:

- **Archiving of communication:** Communication relevant to the research, particularly any interaction involving patients, should be stored following HIPAA guidelines, eliminating PII. Archives should be organized and stored on a secure server, preferably in a secure directory on the web server where it can be recorded for backup.
- **Flow-through mailing of communication:** Mechanisms should be created that allow for automatic classification and redirection of electronic communication received by the site's mail server to the appropriate researchers or staff members.

Transactions – namely *diagnosis*, *testing*, and *prescriptions* – are the most difficult to implement via internet-based interventions, and are rarely attempted in the cited literature. Mechanisms for supporting these transactions must allow the physician the ability to perform the requested transaction without violating *medical ethics*. Physicians who diagnosis conditions electronically must be able to do so with the relative ease and certainty as through traditional means, especially the ability to authenticate the patient and verify the presence of a condition. Web-based testing should only be performed within acceptable risk levels, and if the outcome measures of the tests can be transmitted electronically. As is the case with diagnosis, authenticating patients and verifying the need for requested medications are paramount when prescribing medications via electronic means. McAlindon et al.'s (2003) osteoarthritis clinical trials tested the effects of glucosamine, a safe nutritional product, on osteoarthritis of the knee; with a testing procedure that had a very low risk of complications, McAlindon et al. felt comfortable conducting the experiment remotely. They also stress that osteoarthritis of the knee is relatively easy to diagnose remotely, so they relied heavily on recruitment and diagnosis through electronic means (although, as mentioned earlier, participation in the study depended on the subjects' medical records and their signing of an offline consent form.) Finally, they also argue that testing through electronic means is feasible if the outcome measures of the trials can be transmitted electronically, such as their verified osteoarthritis test that relies on a computer-based self-evaluated questionnaire.

Automated Website Design

Initial meetings were held with M.B. Spring and A.J. Rotondi to review their experiences in developing the websites for NIH studies. They provided access to the software developed for these sites, as well as information about the design process, mistakes and oversights that were made, and other problems encountered. Combining a general design framework developed by Spring intended for conference and proceedings management and the custom-designed software for websites that served as the basis for previous medical intervention research studies, a system was developed that poses a series of questions to principal investigator in terms that they should understand. Based on those answers a fully functional website is developed that can be manually enhanced if the PI so desires. Users specify the design elements of their site and the components they wish to include. These preferences are then dynamically merged with a series of predefined templates to produce the site's pages. The system design and how it addresses the theoretical framework are discussed below.

Information - A series of components were developed to address the presentation and navigational needs of a website, as well as the appropriateness and management of content. The system's Website Options allow the researcher to create the presentation and navigational elements of a website, including:

- Cascading style sheets
- Global website navigation menu
- Website logo
- Color and font schemes for text, links, and backgrounds

Tools are also available to help researchers determine the appropriateness of content in terms of level and detail. Researchers can compute a simple Flesch-Kincaid reading level score for documents, or they can evaluate a document's readability based on the cognitive abilities of its intended audience.

All content added to Webmaster-R is indexed and linked appropriately according to the researcher's preferences. Search functions are built into information-intensive modules, such as resource libraries, using sophisticated document indexing techniques. Threaded discussion boards use simpler database search techniques.

Interaction - Components were developed to provide functionality commonly found on medical intervention research websites to facilitate communication among participants and staff. Interactive modules available through Webmaster-R include:

- Threaded discussion boards
- Blogs, either as personal journals or announcements from staff
- IRC chat
- Video streaming
- Contact forms

Researchers can create multiple instances of the above modules, and specify which groups of participants have access to specific instances. Additionally, researchers have the ability to create their own online questionnaires and specify how 1) they will be presented to users, and 2) how they will be measured for quantitative analysis. Secure mail facilities are included with appropriate modules (i.e. discussion boards, contact forms) to direct communication from participants or the website to appropriate staff members.

Transaction - Components of Webmaster-R can be used for transactions, but in general, the framework stops short of explicitly advocating transaction-type components because of the complex implications, as well as ethical considerations. Even in cases where the medical researcher is also the primary care physician for the intervention's participants, the risks of misidentifying a patient, misdiagnosis, or providing an erroneous prescription often outweighs the benefits of performing a transaction via electronic means. The obstacles to building a general-purpose set of tools for diagnosing any ailment and prescribing any drug electronically via this type of system are great. With cautions, PI's can use components such as self-report surveys and mail – included under the interaction class to approximate transaction interactions.

Content Management & Data Analysis Tools

Content management facilities through a protected administrative section are automatically included with every website created by Webmaster-R. Items in resource and question-and-answer libraries can be added, removed, or edited either directly online or via web upload. Researchers may organize the content in both libraries by categories that may be added or re-labeled online. Access to real-time chat rooms may be granted to groups or specific users through the created website, and full transcripts of all chat room discussions are available at any time. With the consent of participants, researchers can also add and edit profiles, bios, and photos of participants and staff.

Data and log analysis tools are provided to help researchers audit their site's usage, track usage for individual users, and identify potential problems with the sites usability. Website logs are parsed to remove entries that represent support files (i.e., images, external stylesheets and HTML framesets) and filtered to remove visits by staff members. Tools are available to help researchers identify users' sessions, as well as search queries issued by participants. Researchers can then create customized summaries or detailed reports via a web interface. For example, a researcher can produce a report summarizing the number of postings and read messages within a discussion group over a given timeframe, or how many times a particular user accessed specific threads over the duration of the study. Full automation of the data collection has not yet been implemented, but all the tools and procedures have been documented that allow researchers to collect and analyze both web logs and database tables.

Implementation

Webmaster-R was implemented as a Java-based application, producing standard XHTML or JSP documents as output from pre-defined templates. For output that requires database-driven components, Webmaster-R includes a series of preconfigured Java servlets able to communicate with any Microsoft SQL Server database. Included are servlets that automatically write out the necessary database tables for the website, all of whose schema conform to HIPAA guidelines. At the time of this writing, a typical Webmaster-R session of an hour will result in the creation of more than 250 files, most of which are programs that process data, distributed in 25 folders representing almost a Megabyte of data.

Webmaster-R is available for free to anyone in the medical research community to use.

PROTOTYPE EVALUATION

After development of a prototype version of Webmaster-R, meetings were held with two researchers from the University of Pittsburgh who were in the early stages of programs that would entail research on web based medical interventions. The researchers provided more insights into the budget process, usability issues encountered, technical limitations overcome, and techniques used to comply with HIPAA. This section reports on a series of prototype walkthroughs and an initial usability study with a research team developing a new medical intervention research website. After Figure 2, Figure 3 presents a summary of the feedback evaluating the effectiveness of the framework. Five metrics were used:

- Saves money?
- Saves time?
- HIPAA compliant?
- Acceptable usability - application?
- Acceptable usability - resulting websites?

Figure 2. The functional components of Webmaster-R

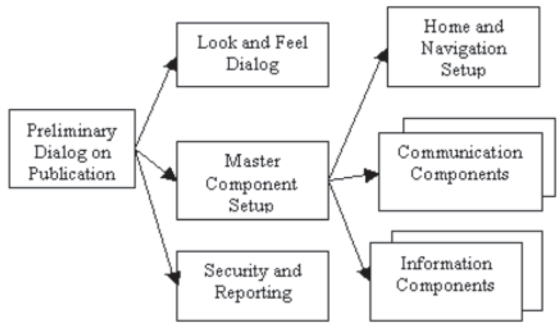

Figure 2 shows the functional components of Webmaster-R. The PI is able to incrementally develop the components, adding and changing the components at any time.

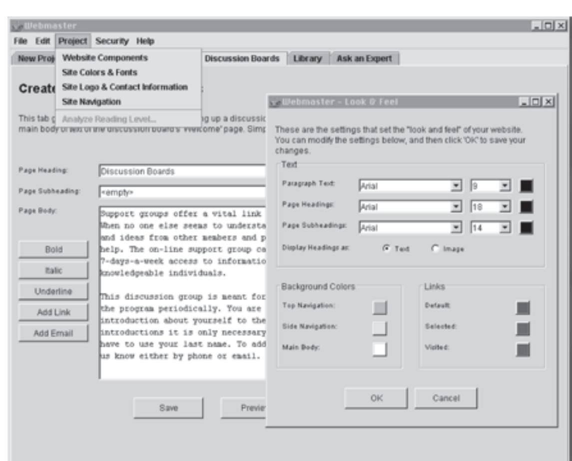
Users can preview their work in HTML as they work, and also have the option of publishing the site to their local computer (for later uploading) or directly to a web server, provided they have a network connection to the server. As the components are added, a system of files is built up recording the decisions. At any time, the basic configuration can be modified or changed. As the PI answers questions that have been designed to make sense to them, complex pre-configured common facilities are added. For example, answering a question such as "Do you want periodic reports of website activity?" will activate code fragments and scripts that will do database queries automatically at specified intervals and mail the results to given email addresses. Answering yes to a simple question will add code and structure that would take at least several hours and, in many cases, several days of programming if done from scratch.

A typical view of Webmaster-R is provided in Figure 3 showing the kinds of information that the PI is expected to provide.

Figure 3. Screenshot of Webmaster-R



Prototype Walkthroughs

The first of three prototype walkthroughs was conducted in July, 2005 with three researchers from the University of Pittsburgh. The walkthrough consisted of a demonstration of an early Webmaster-R prototype, with feedback gathered during and after the demonstration. The Webmaster-R prototype demonstrated at this meeting had fully functional Website Option tools, but only one functional Website component, the Home Page.

Participants were asked the following questions regarding the application:

1. In what areas of research would you utilize a medical intervention website?
2. What special needs of your audience need to be addressed in the design of the site?
3. Are there aspects of Webmaster-R that you feel would be helpful to you?
4. What do you think is missing from Webmaster-R?
5. Does Webmaster-R meet your research needs?
6. Would you consider using Webmaster-R to develop a website?

The initial impressions of Webmaster-R were generally favorable. Two researchers indicated that they would consider using the application to build a medical intervention research website, and that it would reduce the time needed to implement the site. One participant indicated he could not because the websites generated by the program would not meet the usability needs of consumers with cognitive impairments. Participants found the choices of website components suitable for their information and interaction needs, although they could not fully judge the application's ability to reduce development costs or comply with HIPAA without seeing the finished components. They also cited the program's ease of use and ability to generate a website from a small set of preferences as strengths. Participants also indicated, however, that some of the program's user interface elements were confusing, particularly the names of some of the input fields and buttons. They suggested improving the interface by providing more visual cues as to what website content a particular field will generate – for example, pre-filling each component's text fields with descriptive text rather than presenting empty fields.

The suggestions were incorporated into Webmaster-R's user interface, and development continued on the component parts of Webmaster-R. In November, 2005 a second walkthrough was conducted with one of the researchers interviewed in the initial meeting. Website components for discussion boards, resource libraries, and group member profiles had been completed and were demonstrated. The participant indicated that the demonstrated components, as well as the rest of the program would be useful, but that a streaming video component would also be important to her research. The demonstrated components would help her reduce both development time and monetary costs, while still complying with HIPAA regulations. She also indicated that a minimal set of documentation (10-20 pages) should accompany the application as a user's guide. This walkthrough was followed by the initial usability test of the Webmaster-R prototype. Following the meeting, online help documents were created and added to the application.

In the third meeting held in December, 2005, two researchers from the WPIC Behavioral Medicine Program were presented with a complete prototype of Webmaster-R, including design changes incorporated from previous feedback. The researchers were given the option of using the application to prototype the website themselves rather than hire outside consultants to build the site. The researchers indicated the application would be very useful for building a website and would reduce their development costs in terms of both time and money. They found the set website components sufficient for their research. Both researchers still found some of the program's terminology confusing, and felt some of the resulting pages (particularly in the Library component) would be unsuitable for their target audience – i.e. adolescents. Following this meeting, the application's interface and templates were altered to address the researchers' feedback. The changes were implemented prior to the second usability test. A set of documents was also created to help the researchers with issues outside the scope of the program, including 1) instructions for installing the program, 2) generating and saving additional web pages using a word processor, and 3) using document templates to enforce a consistent style across all documents.

Usability Tests

After further development of the prototype based on the feedback from the aforementioned interviews, three usability test sessions were conducted – two with a researcher from the Starzl Transplant Institute (STI) and one with a research assistant from the WPIC Behavioral Medicine Program (WPIC). Both sessions with the STI researcher were conducted as cognitive walkthroughs (Wharton et al., 1994) requiring the researcher to show the steps she would take to 1) begin a website project, 2) add website components to the project, and 3) configure a discussion board for all group members using a prototype of Webmaster-R. The session with the WPIC research assistant was conducted similar to Battleson et al. (2001) using the think-aloud protocol on a more advanced version of the Webmaster-R prototype. The research assistant, who was not familiar with HTML, was asked to start a new website project and complete the following sub-tasks: enter the project's technical settings, design the site's layout, define the website's administrator and contact information, create a navigation menu, add and configure five website components, supply text for the Home Page component, and add at least one hyperlink to the Home Page's text. The goal of each usability test was to assess Webmaster-R's user interface – not necessarily to test if the user could construct a production quality website in one sitting.

Based on the test results and the participants' feedback, the tool shows promise but is not yet a complete solution to researchers' needs. We identified three critical areas where the tool needs to be enhanced:

- **Provide more component choices:** In her second usability session, the STI researcher requested a number of website components that were unavailable in Webmaster-R. Her requested site functionality included components based on "Web 2.0" technologies – technologies that provide a more interactive and seamless experience for visitors. Two such components – a personal blog for patients and a real-time chat requiring only a standard web browser, have since been incorporated into Webmaster-R. Other requested components, such as an online questionnaires and video streaming, are more challenging to include in an automated tool because of the complexity of the final products. For questionnaires, it was relatively easy to construct a tool to build questionnaires based on a series of questions using a Likert scale. The prospect of an instrument with complex logic and varying response types was beyond the scope of this current effort. For video presentations, the tool should not only be able to incorporate items from various multimedia formats, but it should also build presentations that will work for participants with older, slower computers and low-bandwidth Internet connections. Building a streaming media server from scratch was deemed beyond the scope of this effort.
- **Focus on end-user design options:** Another unsolved challenge in Webmaster-R is the

Figure 4. Summary of the evaluations of the effectiveness of the framework

	Walkthrough 1	Walkthrough 2	Walkthrough 3
Saves Time?	Yes	Yes	Yes
Saves Money?	Inconclusive	Yes	Yes
HIPAA Compliant?	Inconclusive	Yes	Yes
Acceptable Usability (Application)?	No	No	Yes
Acceptable Usability (Websites)?	No	Yes	No

lack of mechanisms that ensure a website will have an appropriate design for its intended audience. For example, the WPIC research assistant was able to build a functioning website within 90 minutes, but the text-heavy appearance of the constructed site would have been inappropriate for younger audiences. Other researchers have expressed an interest in building sites that meet the requirements of Section 508 of the Rehabilitation Act to be used by people with cognitive and physical impairments. One potential automated solution to this problem is to ask researchers a series of questions describing the characteristics of their audience, and then using one of a set of pre-defined design templates that is most appropriate for the described audience.

- **Make the tool more usable for researchers:** Our goal is to make Webmaster-R easy for a researcher to use without having to wade through volumes of documentation. Although improvements to the interface made the tool more intuitive for the STI researcher in the second session compared to the first, she found some of the terminology in the directions and labels too technical. In the session with the WPIC research assistant, online help pages were provided to help overcome blocks; however, these pages were never accessed during the session. Visual cues need to be added to the interface that make clear what pieces of information will be viewed "publicly" on the website by consumers and caregivers versus information that it intended for internal purposes only.

CONCLUSION

This chapter introduces a framework for classifying the critical needs of a medical intervention research website. Within this framework four main categories have been identified for describing these critical needs: infrastructure, information, interaction, and transaction. Based upon this underlying framework, the Webmaster-R system was built to test the framework and assess the feasibility of automating the web development process for medical intervention research websites. Preliminary evaluations conducted on the system indicate that researchers find the tool helpful and able to meet most of their research objectives. The formative evaluation indicates that the design tools are not yet flexible enough to meet some specific objectives. Notably, the tools do not yet insure that the resulting material is simple enough for younger audiences, or consumers with cognitive impairments. On the other hand, in 5 different situations, we have been able to reduce the time required to mount a complex automated research website, with most of the work done by the medical researcher his or her self, from three or four months to one to two weeks. Further, the actual time required to obtain a polished final website has been reduced from three to four months of technical work to less than 40 hours.

While these results are promising, much work still needs to be done. The current studies suggest that such a tool can aid in the rapid and inexpensive development of websites that can be used as the basis of clinical trials. At this point in time, there is no guarantee that the resulting sites will be mounted so as to guarantee HIPPA compliance. It is not clear whether it is possible to insure this. In addition, while a number of scripts have been written to aid in the analysis of the data collected via the website, we have treated this process individually to date so as to answer as many of the questions researchers have as possible. We have not found many questions that could not be answered by analysis of the data, but it is not clear that this process could be fully automated at this point. Finally, each researcher we have worked with has asked for additional functionality that we have added to the basic model. This process seems to accelerate as the sophistication of researchers and subjects increases and as the functionality it is possible to realize through browser technology increases. While we have found it easy to extend the framework to accommodate new functionality, each option makes the system more complex from a design perspective. Ultimately, validation of the system ultimately requires the same kind of empirical validation as the studies it endeavors to support - i.e., research studies of interventions based on this tool more successful than research studies using ad hoc site development.

In the introduction we referred to a paper by May et al. (2005), which examines the provision of telehealth services in the United Kingdom. Their work, and this current effort approach the issue of developing supporting evidence of the efficacy of web based interventions from different perspectives. At the same time, the goal is the same – the provision of some degree of medical treatments via new mechanisms. From this perspective, the ultimate goal of this work is the development of tools and systems that make medical services available and accessible to those who need them.

KEY TERMS AND DEFINITIONS

Content Management: The processes and tools that are used to introduce and maintain the content used by an organization or a website.

Data Analysis: Related to a website, data analysis involves the interpretation of logged data maintained generally for a website and specifically related to the needs of researchers.

Intervention Research: In the case of medicine, research that is designed to assess the efficacy of a particular intervention.

Navigation System: A series of website features that allow a user to move from one part of a website to another without error and to keep track of where they are.

Security: Concerns about authentication, access control and data privacy. With respect to a website, it relates to who is allowed to do what on a website and to the assurance that data is kept private, accessible, and its integrity is maintained.

Usability: The measure of the ability of users to navigate a website and use it to accomplish some goal with a minimum of mistakes.

Website Design: The process of gathering requirements, analyzing needs and designing a website that meets those needs.

Chapter 2.4
Designing Web Information Systems for a Framework-Based Construction

ABSTRACT

In the Web Engineering area, many methods and frameworks to support Web Information Systems (WISs) development have already been proposed. Particularly, the use of frameworks and container-based architectures is state-of-the-practice. In this chapter, we present a method for designing framework-based WISs called FrameWeb, which defines a standard architecture for framework-based WISs and a modeling language that extends UML to build diagrams that specifically depict framework-related components. Considering that the Semantic Web has been gaining momentum in the last few years, we also propose an extension to FrameWeb, called S-FrameWeb, that aims to support the development of Semantic WISs.

DOI: 10.4018/978-1-60566-278-7.ch011

INTRODUCTION

The World Wide Web (also referred to as WWW or simply Web) was created as a means to publish documents and make them available to people in many different geographical locations. However, the advent of the Common Gateway Interface (CGI), in 1993, allowed for authors to publish software instead of documents and for visitors to execute them, producing dynamic results.

The evolution of Web development technology and the emergence of high-level languages (such as PHP, ASP, JSP, etc.) and platforms (such as Microsoft .NET and Java Enterprise Edition) allowed for more complex applications to be built on the Web. Soon enough, a handful of large B2C (business-to-consumer, such as online stores) and B2B (business-to-business, such as supply chain management systems) applications were being deployed on the Internet.

Thus, the concept of Web Applications (WebApps) was born. WebApps consist of a set of Web pages or components that interact with the visitor, providing, storing and processing information. WebApps can be informational, interactive, transactional, workflow-based, collaborative work environments, online communities, marketplaces or web portals (Ginige & Murugesan, 2001).

In this chapter, however, we focus on a specific class of Web Applications, called Web-based Information Systems (WISs). WISs are just like traditional information systems, although deployed over the Internet or on an Intranet. These systems are usually data-centric and more focused on functionality rather than content and presentation. Examples are online stores, cooperative environments, and enterprise management systems, among many others.

Although many Software Engineering principles have long been established before the creation of the Web, first-generation WebApps were constructed in an ad-hoc manner, with little or no concern for them. However, with the increase of complexity of the WebApps, which is especially true for WISs, the adoption of methodologies and software processes to support the development team becomes crucial.

Thus, a new discipline and research field was born. Web Engineering (or WebE) can be defined as "the establishment and use of engineering principles and disciplined approaches to the development, deployment and maintenance of Web-based Applications" (Murugesan et al., 1999, p. 2). Pressman (2005) complements this definition stating that WebE borrows many conventional Software Engineering fundamental concepts and principles and, in addition, incorporates specialized process models, software engineering methods adapted to the characteristics of this kind of application and a set of enabling technologies.

In this field, a lot of methods and modeling languages have been proposed. Some well known works are WebML (Ceri et al., 2000), WAE (Conallen, 2002), OOWS (Fons et al., 2003), UWE (Koch et al., 2000), and OOHDM (Schwabe & Rossi, 1998), among others.

Parallel to the academic research, the industry and the developer community have also proposed new technologies to provide a solid Web infrastructure for applications to be built upon, such as frameworks and container-based architectures. Using them we can improve productivity at the coding phase by reusing software that has already been coded, tested and documented by third parties. As their use becomes state-of-the-practice, methods that focus on them during software design could provide a smoother transition from models to source code.

This has motivated us to develop a WebE design method that focuses on frameworks. The Framework-based Design Method for Web Engineering (FrameWeb) (Souza & Falbo, 2007) proposes a basic architecture for developing WebApps and a UML profile for a set of design models that brings concepts used by some categories of frameworks, which are applied in container-based architectures as well.

Meanwhile, many researches have been directed to the construction of what is being considered the future of the WWW: the Semantic Web. Coined by Berners-Lee et al. (2001), the term represents an evolution of the current WWW, referred by some as the "Syntactic Web". In the latter, information is presented in a way that is accessible only to human beings, whereas in the former data is presented both in human-readable and machine-processable formats, in order to promote the development of software agents that would help users carry out their tasks on the Web.

However, for Berners-Lee's vision to become a reality, Web authors and developers must add semantic annotations to their Web Applications. This is neither an easy nor a small task and support from tools and methods is needed. Thus, an extension of FrameWeb was proposed. The Semantic FrameWeb (S-FrameWeb) (Souza et al.,

2007) incorporates into the method activities and guidelines that drive the developer in the definition of the semantics of the WISs, resulting in a "Semantic Web-enabled" application.

The objective of this chapter is to discuss the current research state regarding Web Engineering (methods and modeling languages), frameworks and the Semantic Web, and to present FrameWeb, and its extension S-FrameWeb, as a new method based on best practices for the development of Web-based Information Systems. We close the chapter by presenting future trends and opportunities for this research.

BACKGROUND

Web Engineering was born from the need to apply Software Engineering principles to the construction of WebApps, adapting them to the application's size, complexity and non-functional requirements. A lot of research on methods and modeling languages has already been conducted, providing an extensive background for new research.

Meanwhile, companies and independent developers create frameworks and propose container-based architectures to promote reuse and improve productivity while maintaining good design principles. Furthermore, research on the Semantic Web has been pointing out some directions on what the Web may become in the future.

This section discusses the current state-of-the-art and state-of-the-practice on Web Engineering, modeling languages for WebE, frameworks for development of WebApps and the Semantic Web.

Web Engineering

Web Engineering (or WebE) uses scientific, engineering, and management principles and systematic approaches to successfully develop, deploy, and maintain high-quality WebApps (Murugesan et al., 1999).

As with conventional software engineering, a WebE process starts with the identification of the business needs, followed by project planning. Next, requirements are detailed and modeled, taking into account the analysis and design perspective. Then the application is coded using tools specialized for the Web. Finally, the system is tested and delivered to end-users (Pressman, 2005).

Considering that, in general, the platform in which the system will run is not taken into account before the design phase of the software process, developing a WebApp would be just like developing any other application up to that phase. However, many differences between Web Engineering and Conventional Software Engineering have been identified by researchers and practitioners (Ahmad et al., 2005), such as sensitivity to content, short time frames for delivery, continuous evolution, focus on aesthetics, etc (Pressman, 2005).

This has motivated researchers to propose different methods, modeling languages and frameworks for Web Engineering. The amount of propositions is quite vast, demonstrating that academics and practitioners have not yet elected a standard concerning Web development. In this subsection we briefly present some methods, while the following subsections focus on modeling languages and frameworks.

Web Application Extension (WAE) (Conallen, 2002) defines an iterative and incremental software process, centered on use cases and based on the Rational Unified Process (Krutchen, 2000) and the ICONIX Unified Process (Rosenberg & Scott, 1999). It proposes activities such as business analysis, project planning, configuration management and an iterative process that includes the usual software development cycle from requirement gathering to deployment.

OOWS (Object Oriented Web Solution) (Fons et al., 2003) is an extension of the OO-Method (Pastor et al., 2001) for WebApp specification and development. It divides the software process in two main steps: conceptual modeling and solution development. In the conceptual modeling step, the system specification is obtained by using conceptual models. For that, OOWS introduces new models for representing navigational and presentational characteristics of web applications. In the solution development step, the target platform is determined, and a specific architectural style is chosen. Then, a set of correspondences between abstraction primitives and the elements that implement each tier of the architectural style are applied in order to automatically obtain the final system (Pastor et al., 2003).

The UML-based Web Engineering (UWE) (Koch et al., 2000) is a development process for Web applications with focus on systematic design, personalization and semi-automatic generation. It is an object-oriented, iterative and incremental approach based on the Unified Modeling Language (UML) and the Unified Software Development Process (Jacobson et al., 1999). The notation used for design is a "lightweight" UML profile. The process is composed by requirement analysis, conceptual navigation and presentation design, supplemented with task and deployment modeling and visualization of Web scenarios (Koch & Kraus, 2002).

Lee & Shirani (2004) propose a component-based methodology for WebApp development, which is divided in two major parts: component requirements analysis and component specifications. Analysis begins identifying the required component functions and is followed by a comparison with the functions available in existing components. The component specification phase has three activities: rendering specification, integration specification and interface specification.

The Ariadne Development Method (Díaz et al., 2004) proposes a systematic, flexible, integrative and platform-independent process for specification and evaluation of WebApps and hypermedia systems. This process is composed of three phases: conceptual design, detailed design and evaluation. Each phase is further subdivided into activities, which in turn defines sets of work products to be built.

Díaz et al. (2004, p. 650) also define the hypermedia paradigm as one that "relies on the idea of organizing information as a net of interrelated nodes that can be freely browsed by users selecting links and making use of other advanced navigation tools, such as indexes or maps". We consider hypermedia methods quite different than methods for the development of WISs, as they focus on content and navigational structures instead of functionality and seem to be better suitable for information-driven WebApps.

Although hypermedia development methods are not on our focus, it is worthwhile to cite OOHDM (Object Oriented Hypermedia Design Method) (Schwabe & Rossi, 1998), a well-known method that is representative of hypermedia methods. It was born from the need to represent hypermedia structures such as links, text-based interfaces and navigation, and more recently has also been applied to Web development. For instance, an extension of this method, called OOHDM-Java2 (Jacyntho et al., 2002), was proposed, which consists of a component-based architecture and an implementation framework for the construction of complex WebApps based on modular architectures (e.g. Java EE). The OOHDM process is divided into five steps: requirements gathering, conceptual design, navigational design, abstract interface design and implementation.

During our research we have also found several other methodological approaches that target specific contexts or scenarios, such as:

- The Business Process-Based Methodology (BPBM) (Arch-int & Batanov, 2003), which blends advantages of the structured and object-oriented paradigms for identifying and designing business components. The central idea of business component modeling is reusability of elementary units, which are business activities. An

elementary unit that represents an atomic changeable business process can be implemented with a portable set of Web-based software components;
- The Internet Commerce Development Methodology (ICDM) (Standing, 2002), which is focused on the development of B2C e-commerce applications, emphasizing not only technical aspects, but also strategic, business and managerial aspects.

Some of the methods presented above also propose a modeling language that better suits its purposes, such as WAE and UWE . In the next subsection, some of them are briefly presented.

Modeling Languages for Web Engineering

Modeling languages define notations to be used on the creation of abstract models to solve problems. The Unified Modeling Language (UML) (Booch et al., 2005), for instance, is a modeling language that defines on its metamodel standardized notations for different kinds of models, such as class diagrams and use case diagrams. However, UML does not define when and to which purpose each model should be used.

Hence, methodologies usually present their own modeling language or, as is most commonly seen, use and extend UML, defining a UML Profile. For this purpose, UML includes extension mechanisms, such as stereotypes (definition of a new model element based on an existing one), tagged values (attachment of arbitrary textual information to elements using label/value pairs) and constraints (semantic specification for an existing element, sometimes using a formal language).

Based on these extension mechanisms, Conallen (2002) proposed the Web Application Extensions (WAE), which extends UML to provide Web-specific constructs for modeling WebApps. WAE also advocates the construction of a new model, the User Experience (UX) Model, which defines guidelines for layout and navigation modeling from requirements specification through design. Models, like the navigation diagram, the class diagram and the component diagram (the last two specific for the web tier), use WAE to represent Web components such as screens, server pages, client pages, forms, links and many more.

The UML-based Web Engineering (UWE) (Koch et al., 2000) also defines a UML profile. Based on class and association elements, it defines new elements to describe Web concepts, such as navigation, indexes, guided tours, queries, menus and many others.

Another method that defines a modeling language based on UML is OOWS (Fons et al., 2003). For the construction of the navigational model, UML packages represent navigational contexts and form a directed graph where the arcs denote pre-defined valid navigational paths. Each context is further modeled using a class diagram to show the navigational classes that form them.

Not all modeling languages are UML-based. WebML (Ceri et al., 2000) is an example. It allows developers to model WebApp's functionalities in a high level of abstraction, without committing to any architecture in particular. WebML is based on XML, but uses intuitive graphical representations that can easily be supported by a CASE tool. Its XML form is ideal for automatic generation of source code, producing Web applications automatically from the models.

Methods and modeling languages aid developers mostly during analysis and design of information systems. However, one can also find tools that focus on the implementation phase. In the next subsection, we discuss frameworks that have been extensively used for the development of WISs.

Frameworks for Web Development

WISs have very similar architectural infrastructure. Consequently, after the first systems started to be built, several frameworks that generalize this infrastructure were developed to be reused in future projects. In this context, a framework is viewed as a code artifact that provides ready-to-use components that can be reused via configuration, composition or inheritance. When combined, these frameworks allow large-scale n-tier WISs to be constructed with less coding effort.

Putting together several of these frameworks can produce what we call a container-based architecture. A container is a system that manages objects that have a well-defined life cycle. A container for distributed applications, such as the applications servers for the Java Enterprise Edition (Shannon, 2003), manage objects and offer services such as persistence, transaction management, remoting, directory services, etc.

The use of these frameworks or container-based architectures has a considerable impact in the development of a WIS. Since it is possible to find many frameworks for the exact same task, we categorized them according their objectives into the following classes:

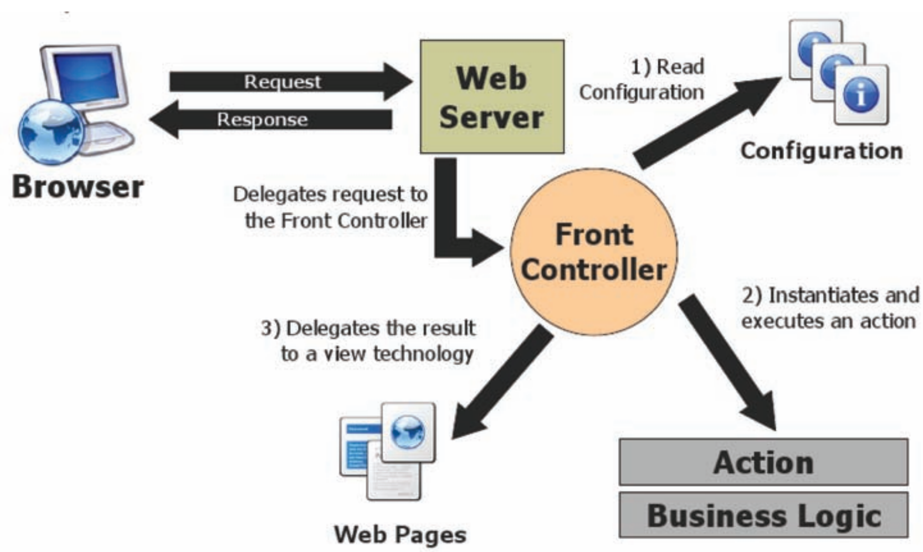
- Front Controller (or MVC) frameworks;
- Decorator frameworks;
- Object/Relational Mapping frameworks;
- Dependency Injection frameworks;
- Aspect-Oriented Programming frameworks;
- Authentication & Authorization frameworks.

Front Controller Frameworks

MVC stands for Model-View-Controller (Gamma et al., 1994). It is a software architecture that was developed by the Xerox PARC for the Smalltalk language in 1979 (Reenskaug, 1979) and has found great acceptance by Web developers. When applied to the Web, the MVC architecture is adapted and receives the name "Front Controller" (Alur et al., 2003, p.166). Both terms are used indistinguishably by Web developers.

The Front Controller architecture is depicted in Figure 1. When structured in this architecture, a WebApp manages all requests from clients using an object known as Front Controller. Based on a customizable configuration, this object decides which class will respond to the current request (the action class). Then, following the Command design pattern (Gamma et al., 1994), it instantiates an object of that class and delegates the control

Figure 1. General architecture of a Front Contoller framework



to it, expecting some kind of response after its execution. Based on that response, the controller decides the appropriate view to present as result, such as a web page, a report, a file download, among other possibilities.

One of these possibilities is using a template engine that defines a template language that is usually more suitable for the view layer than the usual dynamic web technology (such as JSP, ASP or PHP). The template language is usually simpler, making it possible for Web Designers without specific programming skills to build them. Also, they tend to help developers not to break the MVC architecture by restricting what can be done in the template language (e.g. can not directly connect to a database from a template).

MVC Frameworks usually provide the front controller, a super-class or interface for action classes, several result types and a well defined syntax for the configuration file. The template engine is a separate tool, but the framework usually provides integration to it. Note that on n-tier applications, this framework belongs to the Web tier and should delegate business and persistence tasks to components on appropriate tiers.

Only for the Java platform, for instance, there are more than 50 MVC frameworks. Some of the most popular are Struts[1], Spring MVC[2] and Tapestry[3].

Decorator Frameworks

Decorator frameworks automate the otherwise tedious task of making every web page of the site have the same layout, meaning: header, footer, navigational bar, color schemes and other graphical layout elements produced by a Web design team. Figure 2 shows how a decorator framework works.

They work like the Decorator design pattern (Gamma et al., 1994), providing a class that intercepts requests and wraps their responses with an appropriate layout before it is returned to the client. It also provides dynamic selection of decorators, making it easy to create alternate layouts, such as a "print version" of the page. Examples of this kind of framework are SiteMesh[4] and Tiles[5].

Figure 2. The process of decoration of websites

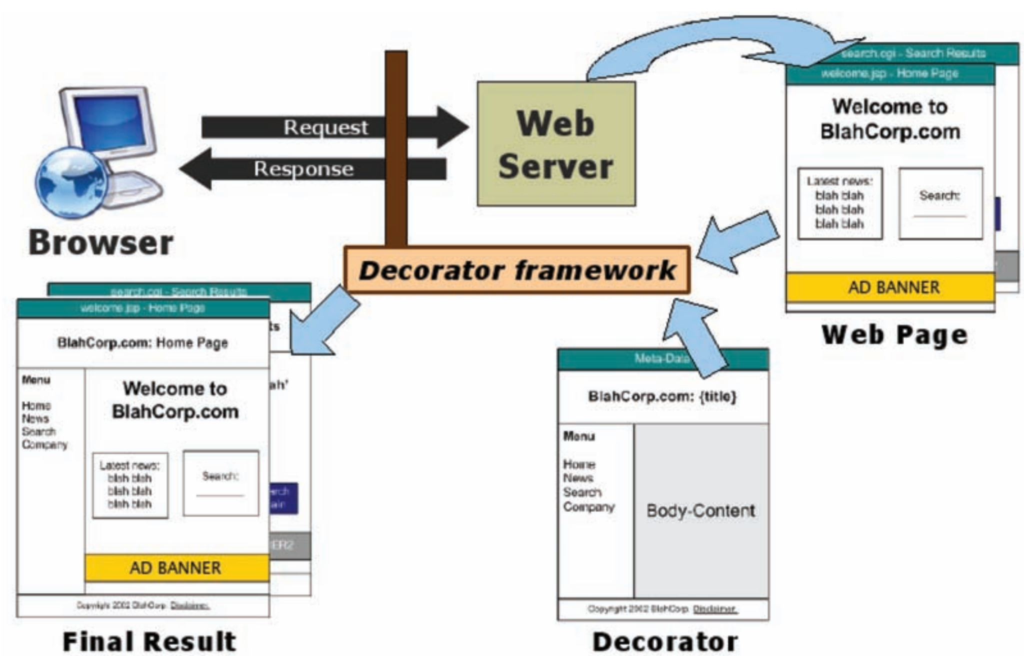


Figure 3. Persistence of objects using an ORM framework

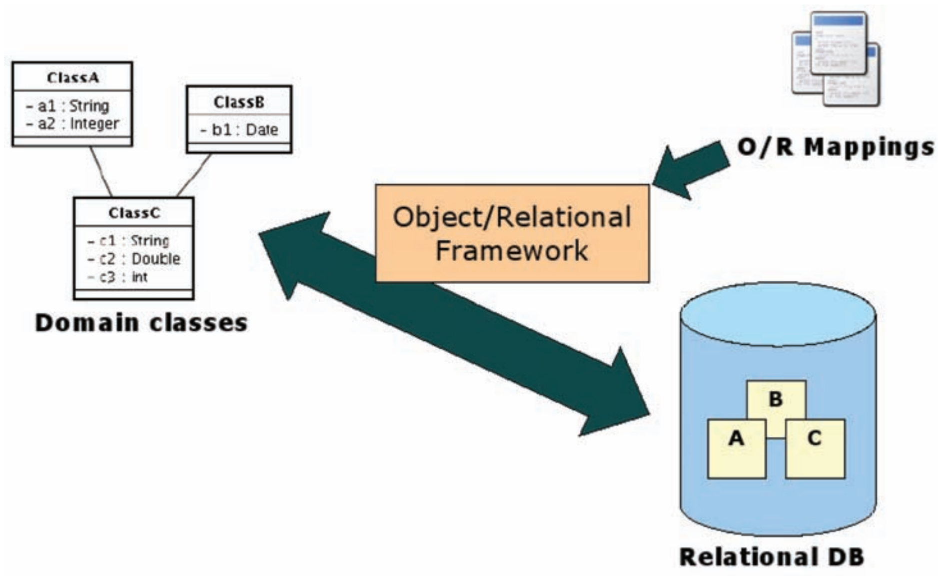


Object/Relational Mapping Frameworks

Relational Database Management Systems (RDBMS) have long been the *de facto* standard for data storage. Because of its theoretical foundations (relational algebra) and strong industry, even object oriented applications use it for object persistence, giving rise to a "paradigm mismatch" (Bauer & King, 2004): tables, rows, projection and other relational concepts are quite different from a graph of interconnected objects and the messages they exchange.

Among the many options to deal with this problem, there is the Object/Relational Mapping (ORM) approach, shown in Figure 3, which is the automatic and transparent persistence of objects to tables of a RDBMS using meta-data that describe the mapping between both worlds (Bauer & King, 2004). Instead of assembling a string with the SQL command, the developer provides mapping meta-data for the classes and call simpler commands, such as save(), delete() or retrieveById(). An object-oriented query language can also be used for more complex retrievals.

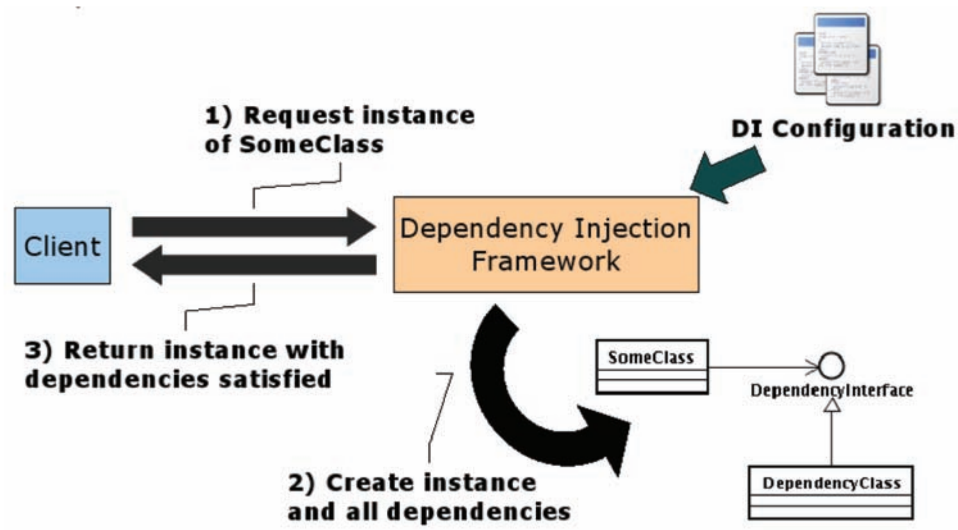
The use of ORM frameworks is not restricted to Web applications and has been in use for quite some time now in all kinds of software. The most popular Java ORM framework is Hibernate[6]. Other well-known frameworks are Java Data Objects[7], Apache Object Relational Bridge[8] and Oracle Toplink[9].

Dependency Injection Frameworks

Object-oriented applications are usually built in tiers, each of which having a separate responsibility. According to Fowler (2007), when we create classes that depend on objects of other classes to perform a certain task, it is preferred that the dependent class is related only to the interface of its dependencies, and not to a specific implementation of that service.

Creational design patterns, such as Factory Method, Abstract Factory and Builder (Gamma et al., 1994), help implementing this good practice in programming, known today as "programming to interfaces, not implementations" (Schmidt, 2007). For instance, if a service class depends on a data access class, it does not need to know

Figure 4. Dependency injection using a framework



how the data access class will perform its duty, but only *what* it will do and what method should be called for the job to be done.

Dependency Injection (DI) frameworks allows the developer to program to interfaces and specify the concrete dependencies as meta-data in a configuration file. When a certain object is obtained from the DI framework, all of its dependencies are automatically injected and satisfied. An abstract example is shown in Figure 4: when the client asks for an instance of SomeClass, the DI framework first satisfies SomeClass' dependencies and delivers the object with all dependencies fulfilled – in the example, an instance of DependencyClass.

These frameworks are also known as Inversion of Control (IoC) frameworks, since the control (who creates the objects) is removed from the dependent classes and given to the framework. As well as ORM frameworks, DI frameworks are not used exclusively for WebApps, although they tend to integrate more seamlessly with applications that run inside containers, just like a WebApp runs inside a Web server. Lots of frameworks provide this service, including Spring Framework, PicoContainer[10], Apache Hivemind[11], etc.

Aspect-Oriented Programming Frameworks

The Aspect-Oriented paradigm is based on the concept of separation of concerns: the idea is to separate different concerns of a system to be treated separately, thus reducing the complexity of development, evolution and integration of software (Resende & Silva, 2005). Although it concerns the whole development process, its biggest influence is at the coding phase, with Aspect Oriented Programming (AOP).

Once a *cross-cutting concern* is identified (e.g.: logging, transaction management), instead of repeating similar code in different points, the functionality can be implemented in a single place, becoming an *aspect*. Then, the different places where that aspect should be applied are identified (these are called *pointcuts*) and, before the code is executed, a process called *weaving* is conducted to automatically spread the aspect all over the code.

The weaving can be conducted by an AOP framework during runtime or by an AOP compiler during compilation time. Many infrastructure concerns that are usual in Web applications are good candidates for this separation, making AOP frameworks very popular. One example, depicted in Figure 5, is that of transaction management. An AOP framework can make all business methods transactional with few configuration steps, avoiding the effort of repeatedly implementing the same logic in all of them.

Some well-known AOP frameworks for the Java platform are AspectJ[12], Spring Framework and JBoss AOP[13].

Authentication & Authorization Frameworks

Another common concern of Web information systems is that of guaranteeing the security of the information. This is usually done by two different procedures: authentication (verifying if an access key is valid to access the application) and authorization (verifying the level of access of the authenticated user and what she is allowed to do).

Being such an important task, frameworks were created to guarantee its proper execution. They can be configured to support many different "auth" methods, using, as usual, meta-data and configuration files. Some well-known auth frameworks for the Java platform are Acegi Security for Spring[14], Apache Cocoon Authentication[15] and the Java Authentication and Authorization Services[16].

In spite of frameworks being much used, there is no Web Engineering method that explores their use in the design phase of the software process. To fill this gap, we proposed FrameWeb, a Framework-based Design Method for Web Engineering (Souza & Falbo, 2007), which is presented later in this chapter.

The Semantic Web

The Semantic Web is being proposed as an evolution of the current WWW, in which information is provided both in human-readable and computer-processable formats, in order to allow for the semi-automation of many tasks that are conducted on the Web.

In order for the software agents to reason with the information on the Web (reasoning meaning that the agents are able to understand it and take sensible actions according to a predefined goal), web pages have to be presented also in a machine-readable form. The most usual way for this is annotating the pages using formal knowledge representation structures, such as ontologies.

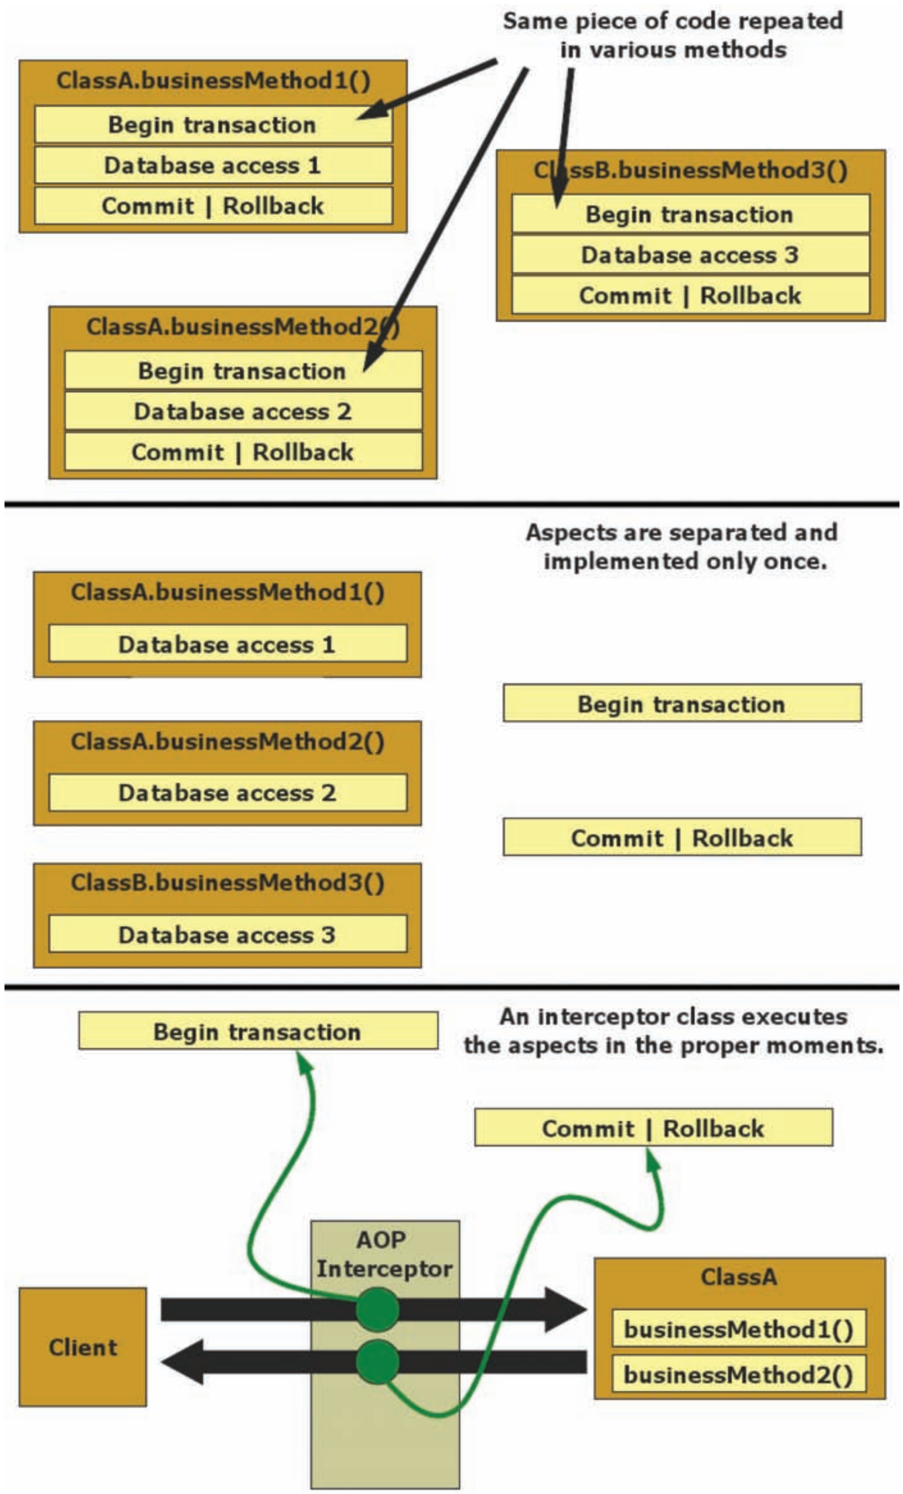
An ontology is an engineering artifact used to describe a certain reality, plus a set of explicit assumptions regarding the intended meaning of its vocabulary words (Guarino, 1998). Along with ontology representation languages such as OWL (W3C, 2007a), they are able to describe information from a website in formal structures with well-defined inference procedures that allow software agents to perform tasks such as consistency checking, to establish relationships between terms and to systematically classify and infer information from explicitly defined data in this structure.

Designing an ontology is not a straightforward task. There are many methodologies for their construction (Gomez-Perez et al., 2005) and attention has to be given to the selection of concepts, their properties, relationships and constraints. However, after the ontology is built, the annotation of static Web pages with languages such as OWL becomes a simple task, especially with the aid of tools, such as OILEd[17] and Protégé[18].

However, several websites have their Web pages dynamically generated by software retrieving information from data repositories (such as relational databases) during runtime. Since these pages cannot be manually annotated prior to their presentation to the visitor, another approach has to be taken. Two approaches that have been proposed are dynamic annotation and semantic Web services.

The former works by recognizing whether the request belongs to a human or a software agent, generating the proper response depending on the

Figure 5. example of application of AOP using an AOP runtime framework



client: in the first case, a HTML human-readable Web page; in the second, a document written in an ontology specification language containing meta-data about the information that would be displayed in the HTML version. Although the solution seems appropriate, many aspects still need to be addressed, such as: how are the agents supposed to find the Web page? How will they know the correct way to interact with it? For instance, how will they know how to fill in an input form to submit to a specific request?

The latter approach is based on Web Services, which are software systems designed to support interoperable machine-to-machine interaction over a network (W3C, 2007b). Web Services provide a nice way for software agents to interact with other systems, requesting services and processing their results. If semantic information is added to the services, they could become interpretable by software agents. Meta-data about the service are written in a markup language, describing its properties and capacities, the interface for its execution, its requirements and the consequences of its use (McIlraith et al., 2001). Many tasks are expected to be automated with this, including service discovery, invocation, interoperation, selection, composition and monitoring (Narayanan & McIlraith, 2002).

As the research on the Semantic Web progresses, methods are proposed to guide developers on building "Semantic Web-enabled" applications. An example of this is the Semantic Hypermedia Design Method (SHDM) (Lima & Schwabe, 2003). Based on OOHDM (Schwabe & Rossi, 1998), SHDM is a comprehensive model-driven approach for the design of Semantic WebApps.

SHDM's process is divided in 5 activities. In the first step, Requirements Gathering, requirements are gathered in the form of scenarios, user interaction diagrams and design patterns. The next phase, Conceptual Design, produces a UML-based conceptual model, which is enriched with navigational constructs in the Navigational Design phase. The last two activities are Abstract Interface Design and Implementation.

Some Considerations

In our research, we haven't found a method focused on the use of frameworks for the construction of WISs nor for the development of Semantic Web applications. In the next sections, we present FrameWeb, our proposal for the design of framework-based WISs, and its extension, S-FrameWeb, which incorporate into the method activities and guidelines that drive the developer in the definition of the semantics of the WISs, resulting in a "Semantic Web-enabled" application.

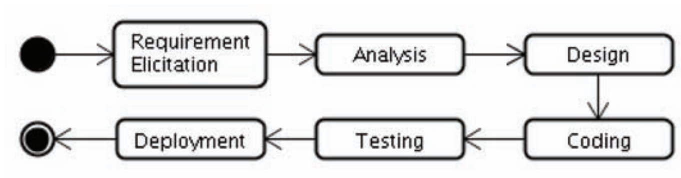
FRAMEWEB

FrameWeb is a design method for the construction of Web-based Information Systems (WISs) based on frameworks. The main motivations for the creation of this method were:

1. The use of frameworks or similar container-based architectures has become the *de facto* standard for the development of distributed applications, especially those based on the Web;
2. There are many propositions in the area of Web Engineering, including methodologies, design methods, modeling languages, frameworks, etc. However, we haven't found one that deals directly with the particularities that are characteristic of the use of frameworks;
3. Using a method that fits directly into the architecture chosen for the implementation promotes a greater agility to the software process, which is something that is desired in most Web projects.

In general, FrameWeb assumes that certain types of frameworks will be used during the

Figure 6. A simple software process suggested by FrameWeb



implementation, defines a basic architecture for WISs and proposes design models that are closer to the implementation of the system using these frameworks.

Being a design method, it doesn't prescribe a complete software process. However, it suggests the use of a development process that includes the following activities, as presented in Figure 6: requirements elicitation, analysis, design, coding, testing and deployment. For a more systematic usage of the method, it also suggests that, during Requirement Elicitation and Analysis, use case diagrams are used to model requirements and class diagrams are used to represent the conceptual model.

Also, as mentioned earlier, one of the motivations for the creation of FrameWeb is the demand for agility that surrounds Web projects. Thus, although the method brings more agility especially to the design and coding phases, developers are advised to follow principles of agility during requirements analysis, as the ones proposed by Agile Modeling (Ambler & Jeffries, 2002).

The main contributions of the method are for the Design phase: (i) the definition of a basic architecture that divides the system in layers with the purpose of integrating better with the frameworks; (ii) a UML profile for the construction of four different design models that bring the concepts used by the frameworks to the design stage of the software process.

Figure 7. A simplified use case diagram for LabES Portal

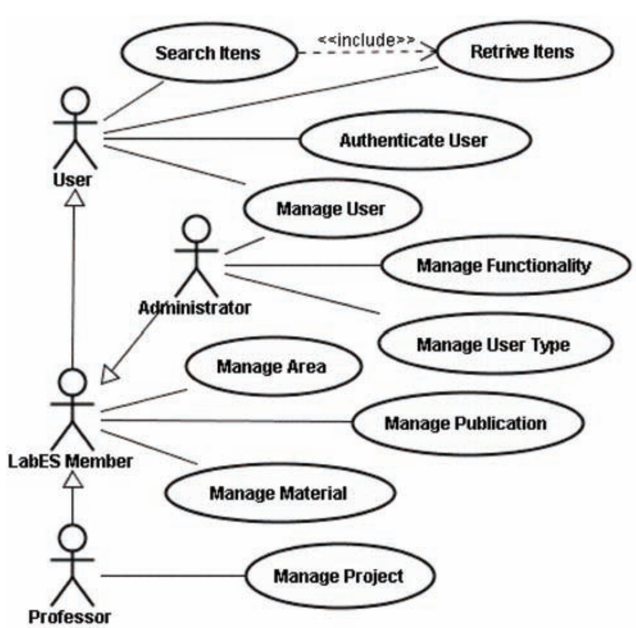


Figure 8. Conceptual model for the User Control module of the LabES Portal

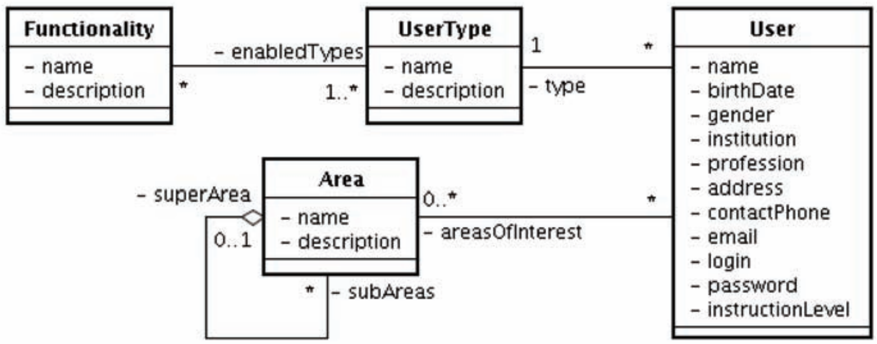
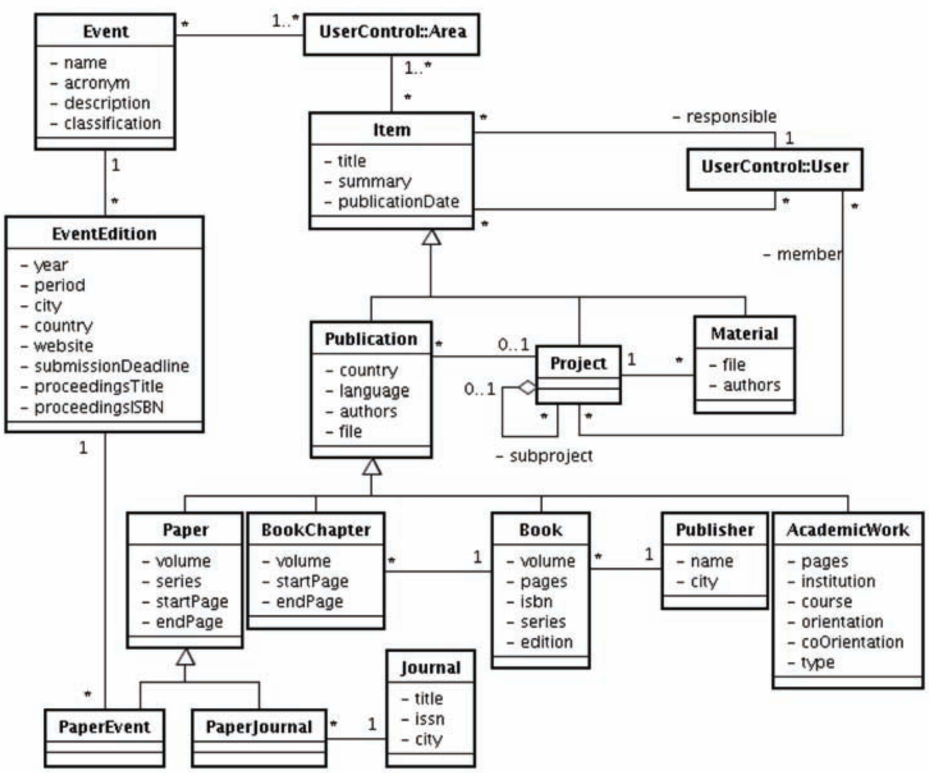


The Coding phase is facilitated by the use of frameworks, especially because design models show components that can be directly related to them. The use of frameworks can also have impacts on Testing and Deployment, but these are yet subject to study and research.

Throughout the next subsections we detail FrameWeb's basic architecture and its UML pro-

Figure 9. Conceptual model of the Item Control module of the LabES Portal



file. Examples diagrams were taken from the development of a portal for the Software Engineering Lab (LabES) of the Federal University of Espírito Santo State using FrameWeb. Figure 7 shows its use case diagram, simplified for brevity.

The "LabES Portal" was proposed to provide a better interaction with the Software Engineering community. This WIS has a basic set of services providing information about current LabES projects, areas of interest, publications and other material available for download. Figures 8 and 9 show the conceptual models produced during Analysis.

Basically, the portal makes a collection of items available. These items can be organized in projects and subprojects or belong to the lab in general. Publications (papers, books, book chapters and academic works) and generic materials can be published in the portal. Items are also related to users (responsible user, editing users) and areas of interest.

Framework-Based WebApp Architecture

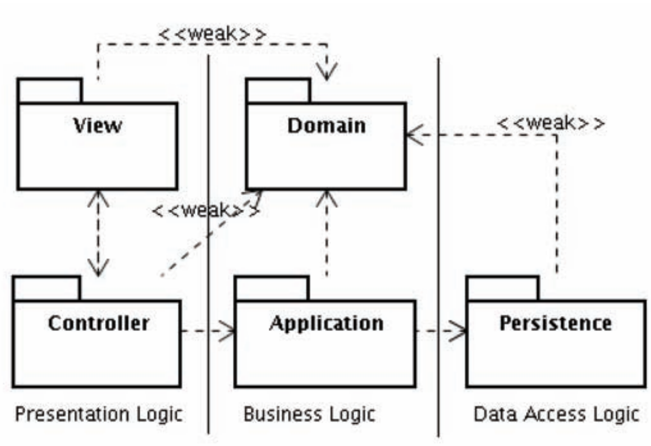
The Design activity, traditionally executed after requirement elicitation and analysis, has as purpose the description of the logical and physical architectures of the system as well as the development of structural and behavioral models built based on the models developed in the previous phases, but that now consider the specific characteristics of the chosen implementation platform.

FrameWeb defines a logical architecture for WISs based on the architectural pattern Service Layer (Fowler, 2002, p. 133). As depicted in Figure 10, the system is divided in three main layers: presentation logic, business logic and data access logic.

The first layer concerns the graphical user interfaces. The View package contains the Web pages, style sheets, images, client-side scripts, templates and everything else related to the exhibition of information to the user. The Controller package encompasses action classes and other files related to the Front Controller framework. These two packages are mutually dependent, since View elements send user *stimuli* to Controller classes while these process the response using pages, models and other View components.

The business logic is implemented in the second layer, divided in two packages: Domain and Application. The former contains classes that represent concepts of the problem domain identified and modeled by the class diagrams during analysis and refined during design. The latter

Figure 10. FrameWeb's basic architecture for WISs



has the responsibility of implementing the use cases defined in the requirements specification, providing a service layer independent of the user interface. The Application classes deal directly with Domain objects to implement system functionality and, thus, this dependency is represented in the diagram.

The Controller package, on the presentation layer, depends on the Application package since it mediates the user access to the system functionalities. User *stimuli* coming from View are transformed by the Controller's classes in method calls to classes in the Application package. Controller and View have also dependency relationships with Domain, but this is tagged as weak to denote low coupling: Domain objects are used only for exhibition of data or as parameters on method invocations between one package and another, i.e., the presentation layer does not have the right to alter domain entities.

The third and last layer regards data access and has only the Persistence package. This package is responsible for the storage and retrieval of persistent objects in long-term duration media, such as databases, file systems, naming services, etc. In the case of FrameWeb, it expects the use of an ORM framework through the Data Access Object (DAO) pattern (ALUR et al., 2003, p. 462). The DAO pattern adds an extra abstraction layer, separating the data access logic of the chosen persistence technology in a way that the Application classes do not know which ORM framework is being used, allowing for its replacement, if necessary. It also facilitates unit testing, as one can provide mock DAOs for the Application classes to be tested alone.

As we can see in Figure 10, the Application package depends on the Persistence package to retrieve, store and delete domain objects as the result of use case execution. Since the Persistence package works with Domain objects, a weak dependency is also portrayed in the figure.

This architecture provides a solid base for the construction of WISs based on the types of frameworks presented earlier in this chapter. Each package contains classes or other elements that integrate with these frameworks and, to model all these elements, FrameWeb proposes a modeling language based on the UML, which is presented next.

Modeling Language

During design, besides specifying the system architecture, the artifacts that will be implemented by the programmers on the coding phase should be modeled. Since FrameWeb is based on the frameworks presented earlier, we felt the need for a modeling language that would represent the concepts that are present in these frameworks.

Following the same approach as other modeling languages such as WAE and UWE, FrameWeb uses UML's lightweight extensions to represent typical Web and framework components, creating a UML profile that is used for the construction of four kinds of diagrams, which are presented in the following subsections: domain model, persistence model, navigation model and application model.

Domain Model

The domain model is a UML class diagram that represents domain objects and their persistence mapping to a relational database. This model is used by the programmers to implement the classes of the Domain package. FrameWeb suggests its construction in two steps:

1. Adapt the conceptual model produced during the Requirement Analysis phase to FrameWeb's architecture and to the chosen platform of implementation. This requires choosing data types for attributes, defining navigabilities of the associations, promoting attributes to classes (if necessary), etc.;
2. Add persistence mappings.

Persistence mappings are meta-data that allow ORM frameworks to convert objects in memory to tuples in Relational Data Base Management Systems and vice-versa. Mappings are added to the domain model using stereotypes and constraints that guide developers in the configuration of the ORM framework during implementation. Despite the fact that these mappings are more related to persistence than domain, they are shown in this model because the classes that are mapped and their attributes are shown here.

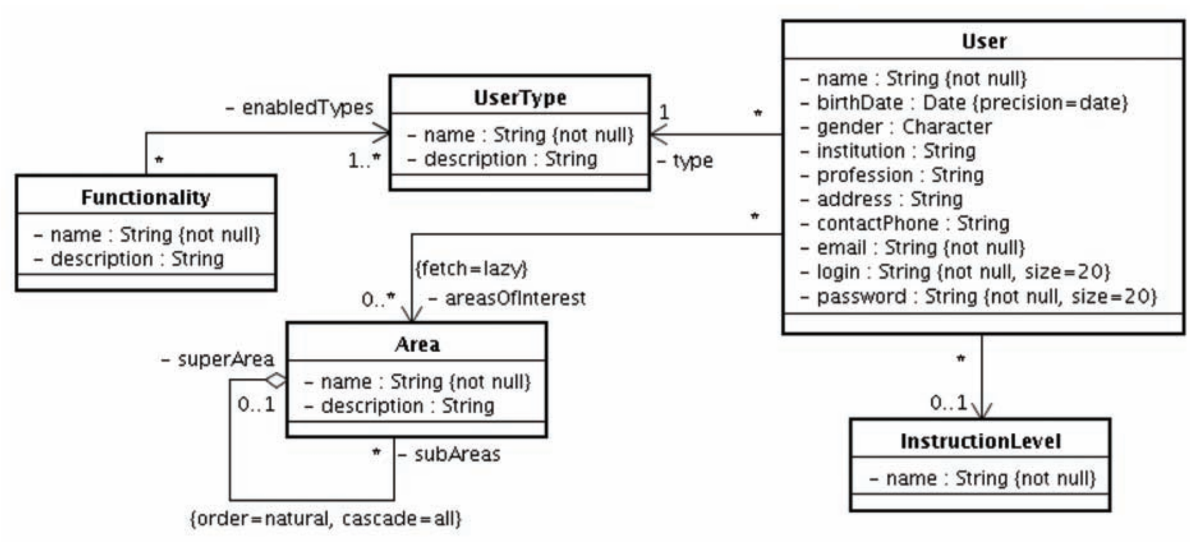
Table 1 describes the possible O/R mappings for the domain model. For each mapping, the table presents the extension mechanism used and what are its possible values or syntax. None of the mappings is mandatory and most of them have sensible defaults, reducing the amount of elements that have to be modeled. The default values are shown in the third column in boldface.

The Domain Model for the User Control module of sLabES Portal is shown in Figure 11. According to the default values, all classes are

Table 1. Possible OR mappings for the Domain Model

Mapping	Extension	Possible Values
If the class is persistent, transient or mapped (not persistent itself, but its properties are persistent if another class inherits them)	Class stereotype	**<<persistent>>** <<transient>> <<mapped>>
Name of the table in which objects of a class will be persisted	Class constraint	table=*name* **(default: class' name)**
If an attribute is persistent or transient	Attribute stereotype	**<<persistent>>** <<transient>>
If an attribute can be null when the object is persisted	Attribute constraint	**null** not null
Date/time precision: store only the date, only the time or both (time-stamp)	Attribute constraint	precision = (date | time | **time-stamp**)
If the attribute is the primary-key of the table	Attribute stereotype	<<id>>
How the ID attribute should be generated: automatically, obtained in a table, use of IDENTITY column, use of SEQUENCE column or none	Attribute constraint	generation = (**auto** | table | identity | sequence | none)
If the attribute represents the versioning column.	Attribute stereotype	<<version>>
If an attribute should be stored in a large object field (e.g.: CLOB, BLOB)	Attribute stereotype	<<lob>>
Name of the column in which an attribute will be persisted	Attribute constraint	column=*name* **(defaults to the attribute's name)**
Size of the column in which an attribute will be persisted	Attribute constraint	size=*value*
If the association should be embedded (instead of having its own table, the associated child class' attributes are placed in the parent's table)	Attribute stereotype	<<embedded>>
Inheritance mapping strategy: one table for each class using UNION, one table for each class using JOIN or single table for the entire hierarchy	Inheritance stereotype	<<union>> <<join>> **<<single-table>>**
Type of collection which implements the association: bag, list, set or map	Association constraint	collection = (bag | list | **set** | map)
Order of an association's collection: natural ordering (implemented in code) or order by columns (ascending or descending)	Association constraint	order = (natural | *column names* [asc | desc])
Cascading of operations through the association: nothing, persists, merges, deletions, refreshs or all	Association constraint	cascade = (**none** | persist | merge | remove | refresh | all)
Association fetching strategy: lazy or eager.	Association constraint	fetch = (lazy | **eager**)

Figure 11. Domain Model for the User Control module of LabES Portal



persistent and class and attribute names are used as table and column names respectively.

As we can see in the diagram, attributes have received mappings such as nullability and size. The birthDate attribute was mapped as date-only precision. The recursive association in Area was configured to be sorted naturally (will be implemented in the programming language) and to cascade all operations (e.g. if an area is deleted, all of its subareas are automatically deleted).

None of the classes have ID or version attributes because they are inherited from a utility package, as shown in Figure 12. The mapped stereotype indicates that DomainObjectSupport and HibernatePersistentObject are not persistent entities, but their subclasses, which are entities, inherit not only their attributes but also their O/R mappings. All domain classes in LabES Portal are said to extend HibernatePersistentObject, inheriting, thus, the UUID[19], the persistence ID and the version attribute.

The parameters I and V are generic, allowing for the user to choose the type of ID and version attributes. HibernateBaseDAO is a base class for data access objects, described in the persistence model, discussed in the next subsection.

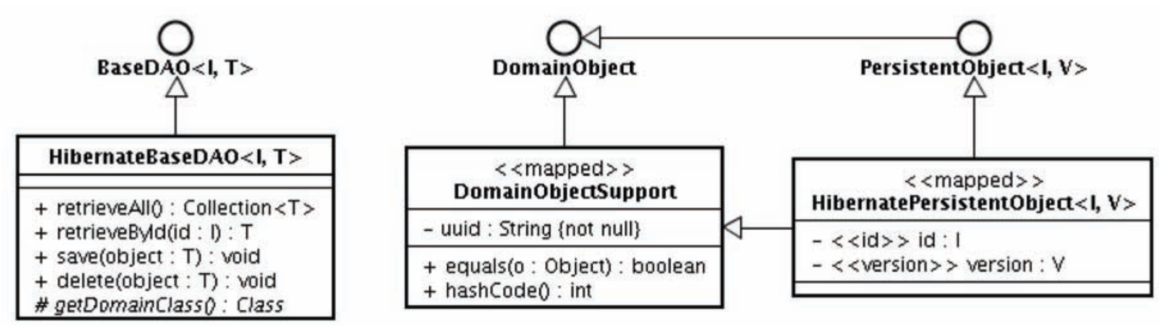
Persistence Model

As mentioned before, FrameWeb indicates the use of the DAO design pattern (ALUR et al., 2003, p. 462) to the construction of the data access layer. Thus, the persistence model is a UML class diagram that represents DAO classes responsible for the persistence of the domain classes. Therefore, it guides the implementation of the classes from the Persistence package. FrameWeb suggests three steps for its construction:

1. Model the interface and concrete implementation of the base DAO (an example is shown in Figure 12);
2. Define which domain classes need basic persistence logic and create a DAO interface and implementation for each one;
3. For each DAO, evaluate the need of specific database queries, adding them as operations in their respective DAOs.

The persistence model presents, for each domain class that needs data access logic, an interface and a concrete DAO that implements the interface. The interface has to be unique and

Figure 12. Utility classes for persistence



defines the persistence methods for a specific domain class. One concrete class is modeled for each persistence technology used.

To avoid repeating in each DAO operations that are common in all of them (e.g.: save, delete, retrieve by ID, etc.), a Base DAO (interface and implementation class) is modeled in a utility package. Automatically all DAO interfaces inherit from the BaseDAO interface and the same happens with concrete implementations, without the need to explicitly state that in the diagram. Also, to avoid repeating methods in the interface and implementations, the designer can choose to display them in one of the two only and it is inferred that all public methods are defined in the interface and implemented in the concrete class.

Figure 12 shows the interface and implementation using Hibernate ORM framework, designed for the LabES Portal project. Both interface and class and declared using generic types, leaving to their subclasses to specify which class is being persisted and what is the type for its ID attribute. The Base DAO defines methods to retrieve all persistent entities of a given class, retrieve an entity given its ID, save and delete an entity. As stated before, all public methods modeled in HibernateBaseDAO are inferred to be defined in the BaseDAO interface.

Figure 13. Persistence model of the User Control module of LabES Portal

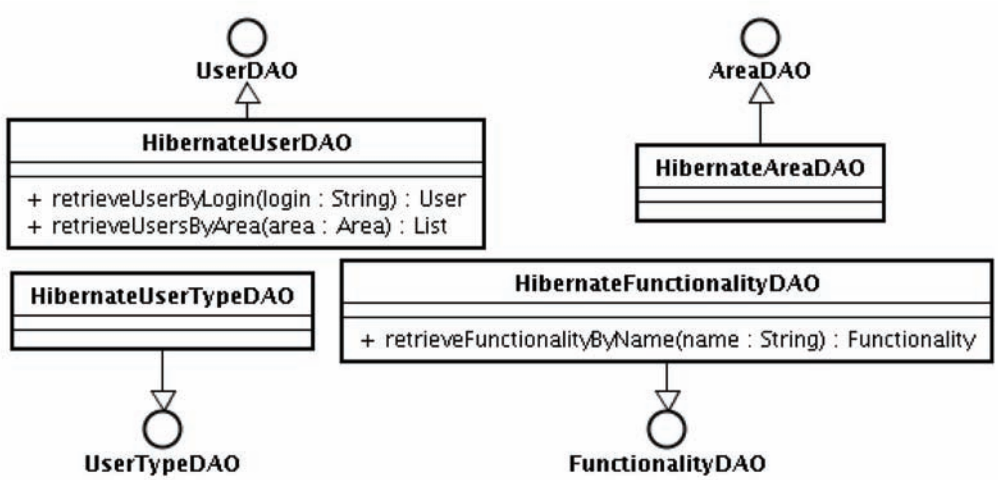


Figure 13 shows the modeling of four DAOs from the LabES Portal project, for the persistence of the classes in the User Control module. AreaDAO and UserTypeDAO are simple, as they inherit all basic operations from the Base DAO and don't need to define any extra ones. The other two define extra operations. For example, UserDAO defines an operation to retrieve all users that have a given area of interest. This is necessary because there is no navigability from Area to User (see Figure 11) and the "Manage Area" use case needs to prevent an area from being deleted if it is associated with any user.

As we can see, the persistence model does not define any UML extensions to represent the concepts that are needed to implement the data access layer, but only some rules that make this modeling simpler and faster.

Navigation Model

The navigation model is a UML class diagram that represents different components that form the presentation layer, such as Web pages, HTML forms and action classes from the Front Controller framework. Table 2 shows the UML stereotypes used by the different elements that can be represented in a navigation model. This model is used by developers to build classes and components of the View and Controller packages.

For Web pages and templates, the attributes of the classes represent information from the domain that is supposed to be displayed in the page. Dependency relationships between them indicate hyperlinks while composition associations between pages and forms denote the presence of the form in that page.

In HTML forms, attributes represent the form fields and their types follow the HTML standard for types of fields (e.g.: input, checkbox, etc.) or the names of the JSP tags used by the framework (e.g., for Struts2, textfield, checkbox, checkboxlist, etc.).

The action class is the main component of the model. Its dependency associations show the control flow when an action is executed. Table 3 lists the different meanings of this kind of association, depending on the components that are connected by it. Dependencies that are navigable towards an action class represent method calls, while the others represent results from the action execution.

The attributes of the action class represent input and output parameters relevant to that action. If there is a homonymous attribute in an HTML form being submitted to the action, it means that the data is injected by the framework in the action class (input parameter). Likewise, when one of the result pages/templates show an attribute with the same name of an attribute of the action class, this indicates that the framework makes this information available for the output.

When an action is executed, the framework will execute a default action method or allow/request the explicit definition of which method to execute. In the latter case, the designer must specify which method is being executed using the constraint {method=method-name} in the

Table 2. UML stereotypes used in the navigation model

Stereotype	What it represents
(none)	An action class, to which the Front Controller framework delegates the execution of the action.
<<page>>	A static or dynamic Web page.
<<template>>	A template that is processed by a template engine and is transformed into a Web page.
<<form>>	A HTML form.
<<binary>>	Any binary file that can be retrieved and displayed by the browser (e.g.: images, reports, documents, etc.).

Table 3. Dependency associations between an action class and other elements

From	To	What it represents
Page / template	Action class	A link in the page/template that triggers the execution of the action.
Form	Action class	Form data are sent to the action class when the form is submitted.
Action class	Page / template	The page/template is shown as one of the results of the action class.
Action class	Binary file	A binary file is shown as one of the results of the action class.
Action class	Action class	An action class is executed as result of another. This process is known as “action chaining”.

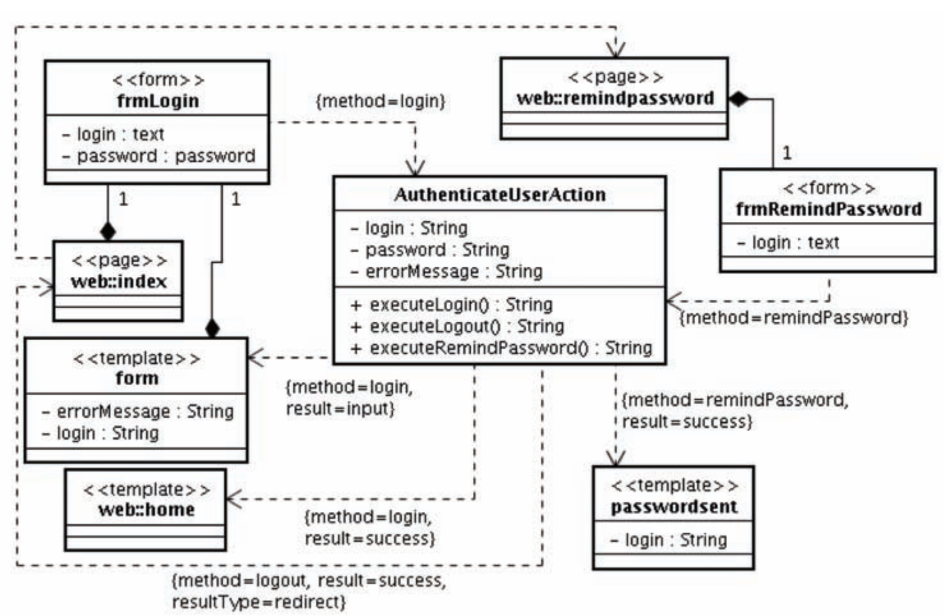
dependency association. The same is true for associations that represent results. Naturally, these methods should be modeled in the diagram.

When modeling action chaining, it’s sometimes necessary to indicate the method that was executed in the first action and the one that will be executed in the following. These can be specified with the constraints outMethod and inMethod.

For dependency associations that represent results there are two other constraints that can be used:

- {result=result name} specifies a keyword that represents this control flow, i.e., when the action class returns this keyword as result of the action execution, the framework will follow this flow and show the appropriate result page/template/binary file;
- {resultType=type name} determines the type of result, among those supported by the framework. Usually, at least the following types of result are available: binary (display a binary file), chain (action chaining), dispatch (dispatches the request), redirect (redirects the request) and template (processes a template using a template engine).

Figure 14. Navigation Model for the use case “Autheticate User”



The difference between a dispatch and a redirection is that the first makes the action's output parameters available to the view, while the second does not. When a dependency association doesn't specify a type, it means it is a dispatch. The default result is defined by the framework.

The designer is free to choose the granularity of the action classes, building one for each use case scenario, one for each use case (encompassing many scenarios), one for multiple use cases, and so forth. Moreover, he/she should decide if it's best to represent many actions in a single diagram or have a separate diagram for each action. Figure 14 is the navigation model for a use case of LabES Portal.

The figure shows that in the initial page of the portal (represented by web::index), there is a form where login and password can be filled. When submitted, this data goes to the action class for the execution of the executeLogin() method, which would access the business logic layer to perform the use case. If the information filled is correct (result = success), the user is taken to web::home, which represents the starting page for authenticated users. Otherwise, the user will be taken back to web::index (result = input), showing once again the login form and an error message.

If the user forgot his/her password, he/she can click on a link in the initial page to go to the web::remindpassword page, where his/her login would be informed and sent to the action class. The executeRemindPassword() method requests the business logic layer to send the password to the user's email address and informs the user that the message has been sent. To log out, the user clicks on the appropriate link and is redirected back to the initial page.

During the conception of FrameWeb, there has been a discussion on whether the navigation model would be better represented by a sequence diagram, as it could represent better the control flow. Two main reasons led to the choice of the class diagram: (a) it provides a better visualization of the inner elements of action classes, pages and forms; and (b) it models composition between pages and forms with a more appropriate notation. Nonetheless, designers are advised to build sequence diagrams to represent complex flows when they see fit.

Last but not least, FrameWeb suggests four steps for the construction of a navigation model:

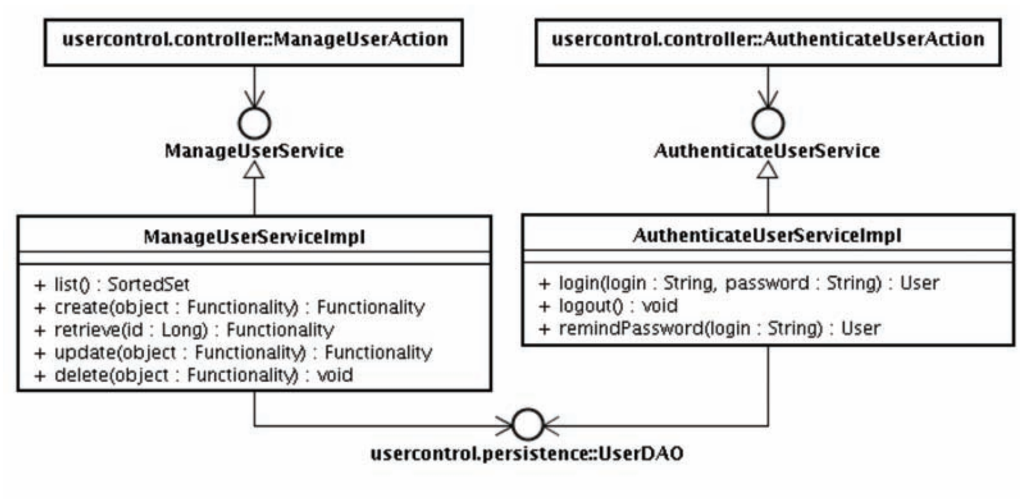
1. Study the use cases modeled during requirements analysis to define the granularity of the action classes (using, preferably, names that can relate the actions to the use cases/scenarios they refer to);
2. Identify how the data gets to the action class, modeling input pages and forms and the appropriate attributes on them and in the action class;
3. Identify what are the possible results and model the output pages/templates/binary files, also adding attributes when appropriate. We suggest that results that come from exceptions should not be modeled to avoid polluting the diagram;
4. Periodically check if the model is getting too complex and consider dividing it into two or more navigation models.

Application Model

The application model is a UML class diagram that represents classes from the Application package and their relationship with the Controller and Persistence packages. Besides guiding the implementation of application classes, this diagram also instructs developers on the configuration of the Dependency Injection framework, which is responsible for managing the dependencies among these three packages.

The granularity of the application classes can be chosen by the developer in the same way as the granularity of the action classes. The application model also shares similarities with the persistence model, as it does not define any UML extension and uses the "programming to interfaces" prin-

Figure 15. Part of an Application Model of the User Control module of LabES Portal



ciple, indicating the modeling of an interface for each application class.

When an application class is modeled, all action classes that depend on it should be displayed in the diagram, with the appropriate namespaces and relationships depicted. Analogously, all DAOs required by the application class to execute the use case should have their interfaces shown in the model, along with the relationship with the application class. Both relationships are represented by directed associations and the multiplicity is not required, as it is always 1.

Figure 15 shows part of an application model of LabES Portal, depicting the classes that implements the "Manage User" and "Authenticate User" use cases and its relationships with controller and persistence components. The methods of the classes represent each scenario of each use case and define the parameters that should be given for them.

Application classes manipulate domain objects and, thus, depend on them. These relationships, however, are not shown in the diagram to avoid increasing the complexity of the model. One can know about these relationships by reading the description of each use case.

FrameWeb suggests four steps for the construction of an application model:

1. Study the use cases modeled during analysis to define the granularity of the application classes (using, preferably, names that can relate the classes to the use cases/scenarios they implement);
2. Add to the interfaces/classes the methods that implement the business logic, giving special attention to the name of the method (as before, with the name of the class), its parameter, the parameters types and its return type;
3. By reading the use case descriptions, identify which DAOs are necessary for each application class and model the associations;
4. Go back to the navigation model (if already built) and identify which action classes depend on which application class and model their associations.

By defining the standard architecture and a UML profile for the construction of these four diagrams, FrameWeb provides the appropriate tools for the design of framework-based WISs.

To promote the construction of "Semantic Web-enabled" WISs, an extension called S-FrameWeb was proposed and it is presented in the next section.

S-FRAMEWEB

The main goal of S-FrameWeb is to make WISs "Semantic Web-enabled". Being a framework-centered method, the chosen approach is to have the Front Controller framework produce dynamic annotations by identifying if requests come from human or software agents. In the former case, the usual Web page is presented, while in the latter, an OWL document is returned.

To accomplish this, S-FrameWeb extends FrameWeb in the following manners:

- The activity of Domain Analysis should be conducted in the beginning of the project to build an ontology for the domain in which the software is based. If it already exists, it should be reused (and eventually modified);
- Requirement Specification and Analysis go as usual, except for the fact that conceptual models build during Analysis can now be based on the domain ontology built in the previous activity;
- During design, FrameWeb's Domain Model (FDM) receives semantic annotations based on the domain ontology;
- During implementation, the MVC framework has to be extended in order to perform dynamic annotation.

Figure 16 shows the software process suggested by S-FrameWeb while Table 4 summarizes the evolution of the models throughout that software process.

The following subsections go through the suggested software process discussing it in more detail.

Domain Analysis

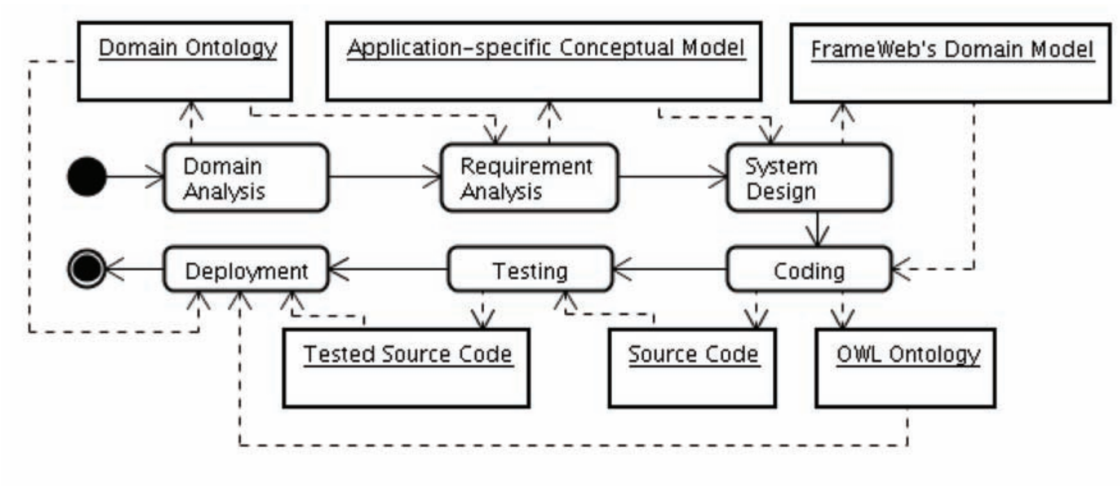
The first step for bringing a WIS to the Semantic Web is formally describing its domain. As discussed previously in this chapter, this can be achieved by the construction of an ontology. S-FrameWeb indicates the inclusion of a Domain Analysis activity in the software process for the development of a domain ontology (we don't use the term "domain model" to avoid confusion with FrameWeb's Domain Model – FDM –, which is a design model).

Domain Analysis is "the activity of identifying the objects and operations of a class of similar systems in a particular problem domain" (Neighbors, 1981; Falbo et al., 2002). When a software is built, the purpose is to solve a problem from a given domain of expertise, such as medicine, sales or car manufacturing. If the domain is analyzed prior to the analysis of the problem, the knowledge that is formalized about the domain can be reused when another problem from the same domain needs a software solution (Falbo et al., 2002).

S-FrameWeb does not impose any specific method for the construction of ontologies. It also doesn't require a specific representation language, but suggests the use of OMG's[20] Ontology Definition Metamodel (ODM) (OMG, 2007), "a language for modeling Semantic Web ontologies in the context of MDA" (Đurić, 2004). ODM defines an ontology UML profile that allows developers to represent ontologies in UML class diagrams.

In the development of the LabES Portal, the SABiO method (Falbo, 2004) was followed, resulting in the construction of an ontology for educational portals that deals with competency questions such as: what are the roles of the people in the educational institution?, what are the areas of interest of these people and the institution?, how is the institution organized?, etc. The ontology was divided into two separate diagrams: one for the general structure of educational protals and another specific for publications. Figure 17 shows the first one.

Figure 16. The software process suggested by S-FrameWeb (SOUZA et al., 2007)



The domain ontology serves as a basis for the construction of the application's conceptual model (during Requirement Analysis), which should derive some classes and associations from the ontology, adding and modifying elements as needed, concerning the specific problem being solved.

Requirement Specification and Analysis

The activities of Requirement Specification and Analysis should be conducted by the development team using its methodology of preference. S-FrameWeb, like FrameWeb, does not prescribe any methods or languages to this phase of the software process. However, as during Domain Analysis, it suggests the use of ODM for the graphical representation of the conceptual model, as it eases its conversion to FDM and, later on, to code (using OWL).

Figure 18 shows the conceptual model for the User Control module of the LabES Portal.

The stereotype <<OntClass>> indicates domain classes, <<ObjectProperty>> models associations between domain classes, <<DataType>> represents XML data types and <<DatatypeProperty>> models associations between classes and data types.

The reader accustomed with UML conceptual models may notice that associations are represented as classes in ODM. This is because in OWL associations are independent from classes and, for instance, can form their own subsumption

Table 4. Models produced by the software process suggested by S-FrameWeb (SOUZA et al., 2007)

Activity	Artifact	What the model represents
Domain Analysis	Domain Ontology	Concepts from the domain to which the software is being built. Modeled in ODM, but converted to OWL for deployment.
Requirement Analysis	Conceptual Model	Concepts that are specific to the problem being solved. Modeled in ODM.
System Design	FrameWeb's Domain Model (FDM)	Same as above plus OR mappings. Modeled using S-FrameWeb's UML profile.
Coding	OWL code	OWL representation of FDM, without OR mappings.

Figure 17. Diagram of the structural part of the ontology for educational portals

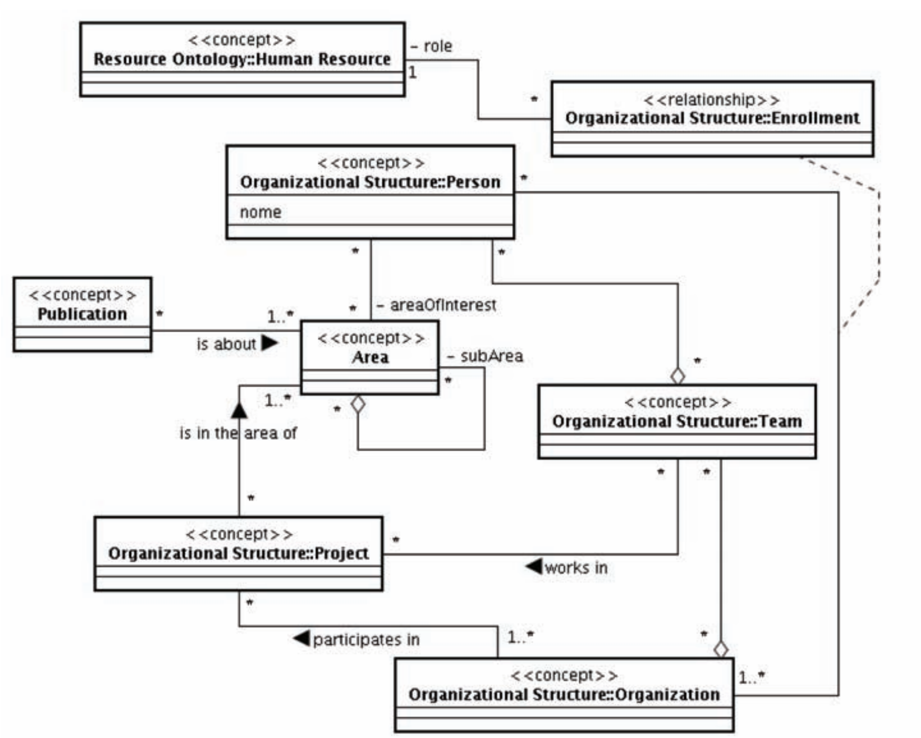


Figure 18. The conceptual model for the User Control module of LabES Portal, in ODM

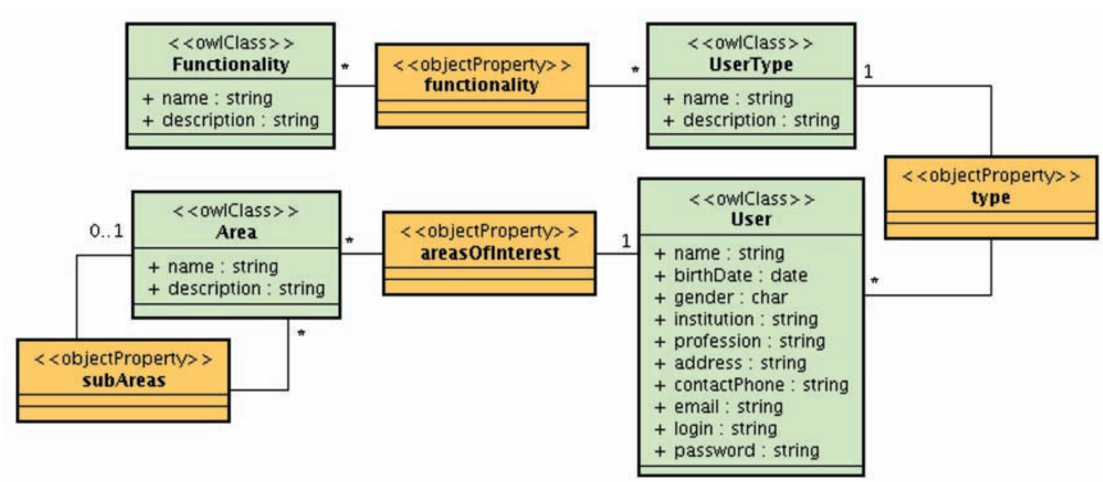

hierarchy. This could also happen with attributes, for the same reasons. More on ODM's semantics can be found at (OMG, 2007).

In the cases where there is no need to represent associations or attributes as UML classes, S-FrameWeb suggests the conceptual model is simplified, such as the one shown in Figure 19. Notice that this diagram is very similar to the one in Figure 8.

Design

As discussed before, FrameWeb proposes the creation of four kinds of models during design: domain, persistence, navigation and application models. These models are still used with S-FrameWeb, although the domain model (FDM) should be adapted to a representation more suitable to the purposes of this semantic extension. Therefore, S-FrameWeb suggests a new UML profile for this diagram, mixing the profile defined by ODM with the one proposed by FrameWeb.

This new modeling language consists basically of the one defined by ODM, with the following adaptations:

1. Specification of association navigabilities for the implementation of the classes;
2. Addition of the O/R mappings for the configuration of the ORM framework;
3. Use of the data types of the implementation platform instead of those defined by the XML Schema Definition (XSD) standard[21];
4. Simplification of ODM's syntax when possible (if not already done previously).

Naturally, the construction of the FDM should be based on the conceptual model already built in previous activities. Figure 20 shows the FDM for the LabES Portal. We can see that, based on the simplified version of the conceptual model, association navigabilities were defined, data types were chosen among those of the implementation platform and that some O/R mappings were included. The result is very similar of that of Figure 11, due to the simplifications performed.

The representation of this model in a language that mixes profiles from both ODM and FrameWeb attempts to facilitate the implementation phase, when an OWL file representing the conceptual model should be created and the ORM framework should be configured.

Implementation, Testing and Deployment

During implementation, the classes that, integrated with the frameworks, provide a software solution to the problem at hand are developed. S-FrameWeb adds a new task to this activity: the construction of OWL files representing the domain ontology and the application conceptual model (based on the FDM). As stated before, this task is facilitated by the use of ODM in both models.

The OWL files should be used by the Front Controller framework to implement dynamic

Figure 19. The conceptual model for the User Control module of LabES Portal, in its simplified version

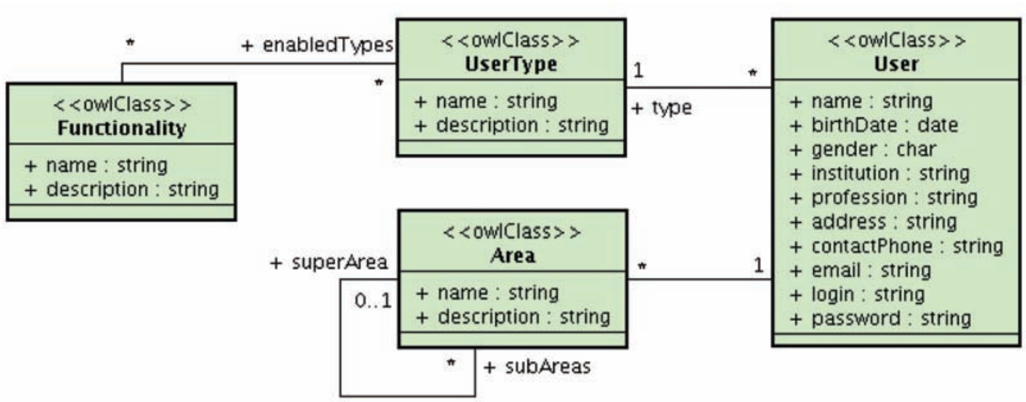

Figure 20. S-FrameWeb's Domain Model for the User Control module of LabES Portal

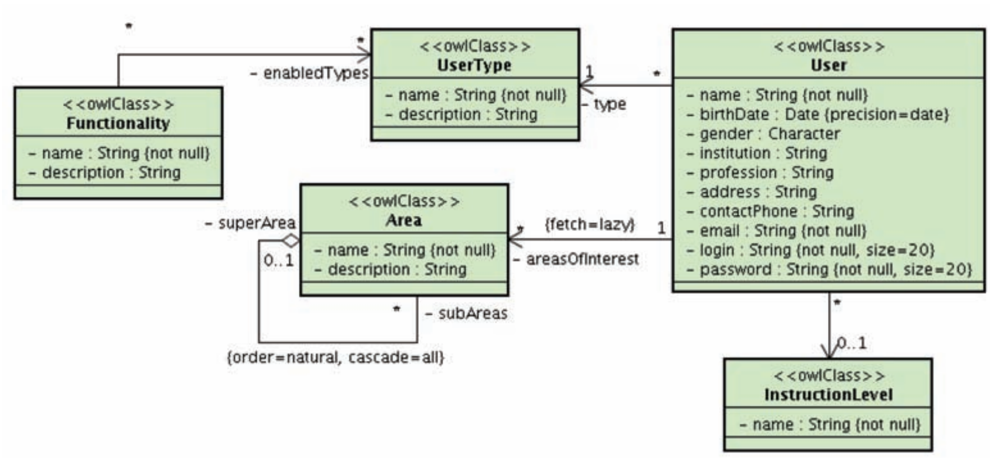

annotation on the Web pages. S-FrameWeb proposes an extension to this kind of framework that recognizes when a request comes from a human or from a software agent by analyzing a specific HTTP request parameter (e.g. owl=true). In the case of a software agent, the framework should respond with an OWL file that is based on the domain ontology and the conceptual model, and represents the data that would be shown in the human-readable version of the page.

To experiment this approach in practice, a prototype of an extension for the Struts2 framework was built. Figure 21 shows this extension and how it integrates with the framework. The client's web browser issues a request for an action to the framework. Before the action gets executed, the controller automatically dispatches the request through a stack of interceptors, following the pipes and filters architectural style.

An "OWL Interceptor" was developed and placed as first of the stack. When the request is made, this interceptor verifies the HTTP parameter and, if present, creates a pre-result listener that will deviate successful requests to the "OWL Result Class", another custom-made component that is responsible for producing this result.

The listing below is an excerpt of an OWL document produced by the search of publications with "FrameWeb" in their names. Publications that are returned by the applications are placed under the <results> tag, while objects associated with them are placed under <instancesList> tag. The association is made using the UUID of each object. See Figure 21.

Since this result should be based on the application ontology, it was necessary to use an ontology parser. For this purpose, we chose the Jena Ontology API, a framework that provides a programmatic environment for many ontology languages, including OWL. With Jena and Java's reflection mechanisms, the OWL Result Class reads all properties that are made available to the Web page by the action, produces an OWL document containing their information and delivers it to the software agent.

Testing should be conducted in order to check not only the source code, but also the ontologies codified in OWL. In the context of S-FrameWeb, however, this is still open to research and study. Deployment works as the same as other WISs, but should also include the OWL files in a specific place in order to be used by the Front Controller's extension.

FUTURE TRENDS

Web Engineering is a relatively new field of research. New methods, languages and frameworks are proposed to provide practitioners with tools that can facilitate and increase the productivity when developing WebApps.

FrameWeb is a new tool, targeting WISs that have their architecture based on frameworks. By suggesting a standard architecture and bringing concepts from the frameworks to the design models, developers can translate models to code more easily and designer have more control on the outcome of the implementation.

FrameWeb was first applied in the development of the Portal of the Software Engineering Lab – LabES. First, developers were trained in general concepts of Web Engineering, in the use of FrameWeb and also in the following frameworks: WebWork2, FreeMarker (template engine), SiteMesh, Hibernate and Spring.

In general, the development went smoothly. The method allowed the developers to deliver the models mostly in time and few deadlines had to be extended. However, some developers had difficulties on capturing the idea of some frameworks, especially the MVC framework. All of them had some experience with the Java platform, but most did not have any experience with Web development.

At the end of the development, the developers were asked to provide feedback on the work done. This feedback can be summarized in the following items:

- Allowing to directly model aspects related to the use of frameworks is the biggest strength of FrameWeb;
- Implementing in Java what was modeled during design was very much facilitated by the clear understanding of the semantics of the four models (domain, persistence, navigation and application);
- The simplicity of the models facilitated the adoption of FrameWeb, except for the navigation model, which added some complexity to the method.

Two other case studies were conducted. The local Java User Group ESJUG[22] modeled a collaborative learning environment called JSchool[23] using FrameWeb for the same set of frameworks used in the LabES Portal project. This helped mature the method in its initial version.

Another case study reimplemented the LabES Portal changing the Front Controller framework. This helped identify some extensions that should be added to FrameWeb in order to cope with some characteristics of different frameworks. For instance, this work suggested the addition of the <<formBean>> stereotype for the navigation model to represent how the framework Struts sends data from the web page to the action class. It also reached the conclusion that the navigation model in FrameWeb is somewhat dependent on the instance of Front Controller frameworks used, and not generic as it was assumed before.

More case studies should be conducted to assess the effectiveness of the method and its appropriateness to different instances of frameworks. Many improvements can come from more practical experiences.

The use of framework-based architectures is becoming the standard for implementation of medium-to-large-sized WIS. Taking the Java platform as example, the definition of standards as JavaServer Faces (JSF)[24] for Web development and the new Enterprise JavaBeans (version 3.0)[25] for distributed components reinforce that conclusion. JSF defines a MVC-like architecture, and EJB 3.0 had all of its persistence model reconstructed based on Hibernate ORM framework and also makes heavy use of Dependency Injection.

The research on the Semantic Web points out to the future of the World Wide Web. Methods for the development of WISs should prepare for, or even help build, this new paradigm. S-FrameWeb suggests a software process that facilitates the development of Semantic WISs by automating certain tasks concerning the generation of semantic annotations on dynamic Web pages. Nonetheless, FrameWeb and S-FrameWeb are far from ideal: there are several opportunities to improve the method. Future work may include:

- Further research on the impact of the use of frameworks and FrameWeb on the activity of Testing. The current work provides no discussion on the subject of testing;
- Proposals on layout and interaction models. Complete methods for the design of WebApps should include models that model aesthetics and usability;
- Conduction of more formal experiments with the method, evaluating more precisely the gains in the productivity of the development team. Currently, only informal experiments have been conducted and conclusions have been reached by requesting developer's opinions;
- Tools could be developed to help create the models or to convert the models to code, automatically implementing much of the infrastructure code and configuration for the most used frameworks available;
- To make FrameWeb's models more generic, the development of an ontology on Web Applications and frameworks to guide the evolution of FrameWeb's modeling language. New concepts brought by new frameworks could be included in the ontology and, thus, taken to the modeling language;
- Continuation on the research on the Semantic Web and in-practice experiments on the construction of a Semantic WIS using S-FrameWeb;
- Deeper discussions on how to tackle specific Semantic Web issues such as: how will agents find the desired web page?, how will they know how to interact with it?, how will they know if a concept "table" refers to a piece of furniture or a systematic arrangement of data usually in rows and columns?, will a top-level ontology be used for all the Internet?

- Evaluation on how to use Semantic Web Services with S-FrameWeb instead of the dynamic page approach and a comparison of both solutions.

CONCLUSION

The amount of propositions in the Web Engineering area, including methods, frameworks and modeling languages, is quite vast, demonstrating that academics and practitioners haven't yet elected a standard when it comes to Web development.

Parallel to this, many frameworks and containers for the implementation of WISs were created, denoting the need for a basic infra-structure that helps on the quick development of reliable software with low future maintenance costs. With several ready-to-use and extensively tested components, frameworks promote reuse and good programming practices.

The large utilization of these frameworks and containers by practitioners and the absence of a design method directed to them has motivated the proposal of FrameWeb, a method based on frameworks for the design of WISs. The current research on the Semantic Web, with many efforts on bringing this idea to reality has impelled us to extend this method and create S-FrameWeb: a method based in frameworks to the construction of semantic WISs.

Given all of the options available, FrameWeb comes in as another one that targets a specific architecture, one based on the use of frameworks. In this case, FrameWeb excels for its agility, because models are directed towards the framework architectures and allow for quick understanding of the implementation. It also doesn't introduce much complexity, allowing organizations to use their own processes up to design with few adaptations, if any. Of all the proposed design models, the navigation model is the only one we consider a little bit complex, making FrameWeb very easy to learn and use.

S-FrameWeb complements FrameWeb, adding activities that promote the construction of Semantic WISs. Given that the Semantic Web vision will not come true unless Web authors add semantic to their websites, S-FrameWeb is a step in that direction, giving directives for WISs developers to follow in order to add Semantic to Web Applications.

Chapter 2.5

Focused Requirements Engineering Method for Web Application Development

Ala M. Abu-Samaha
Amman University, Jordan

Lana S. Al-Salem
SpecTec Ltd & MEP, Greece

INTRODUCTION

The requirements phase of the system/application development process typically involves the activities of requirements elicitation, analysis, validation, and specification. The main goal of such a process is "to develop a requirements specification document which defines the system to be procured and which can act as a basis for the system design" (Sawyer, Sommerville, & Viller, 1996). Hence the underpinning assumption of the requirements engineering (RE) process is to transform the operational needs of an organisation into complete, consistent, and unambiguous system/application specifications through an iterative process of definition and validation (Pohl, 1994).

DOI: 10.4018/978-1-60566-026-4.ch244

The Web engineering (WE) literature provides a limited number of methods and techniques that can be used to manage the RE process in a Web development context [*e*^{3}*-value* framework (Gordijn, Akkermans, & van Vliet, 2000), SOARE approach (Bleistein, Aurum, Cox, & Ray, 2004), e-prototyping (Bleek, Jeenicke, & Klischewski, 2002), AWARE (Bolchini & Paolini, 2004), and SSM/ICDT (Meldrum & Rose, 2004)]. Despite the availability of such a limited number of Web requirements engineering (WRE) methods, many researchers criticised such methods for their failure to address the necessity to align the Web application' requirements to the organisation's business strategy. Hence, the recommendation of many researchers (Al-Salem & Abu-Samaha, 2005a; Bleistein 2005; Bleistein, Cox, & Verner, 2004; Vidgen, Avison, Wood, & Wood-Harper, 2002) is to utilise a general WRE framework for the development of Web applications that can align the application's requirements to the organisation's business needs and its future vision. The objective of such a WRE framework is to incorporate the elicitation/analysis of business strategy as part of the application's RE process.

This chapter presents a WRE method that extends Sommerville and Kotonya's viewpoint-oriented requirements definition (VORD) and Kaplan and Norton's balanced scorecard (BSC) to elicit the Web application' requirements and to plan/analyze the business strategy, respectively. In addition, eWARE (extended Web application requirements engineering) deploys the concept of "requirements alignment" to attain business objectives during the requirements discovery, elicitation, and formalisation process to identify the services of the Web application that will achieve the business objectives in order to improve the organisation's profitability and competitiveness. The chapter is organised into a number of sections. The second section of this chapter provides a background to Web applications in terms of definition and differentiating characteristics. The third section provides a discussion of eWARE method in terms of phases and activities. This section is divided into two subsections to cover the activities of the two prominent phases of the eWARE process in more detail. The fourth and fifth sections provide a discussion of possible future trends in WRE and a number of concluding remarks.

BACKGROUND

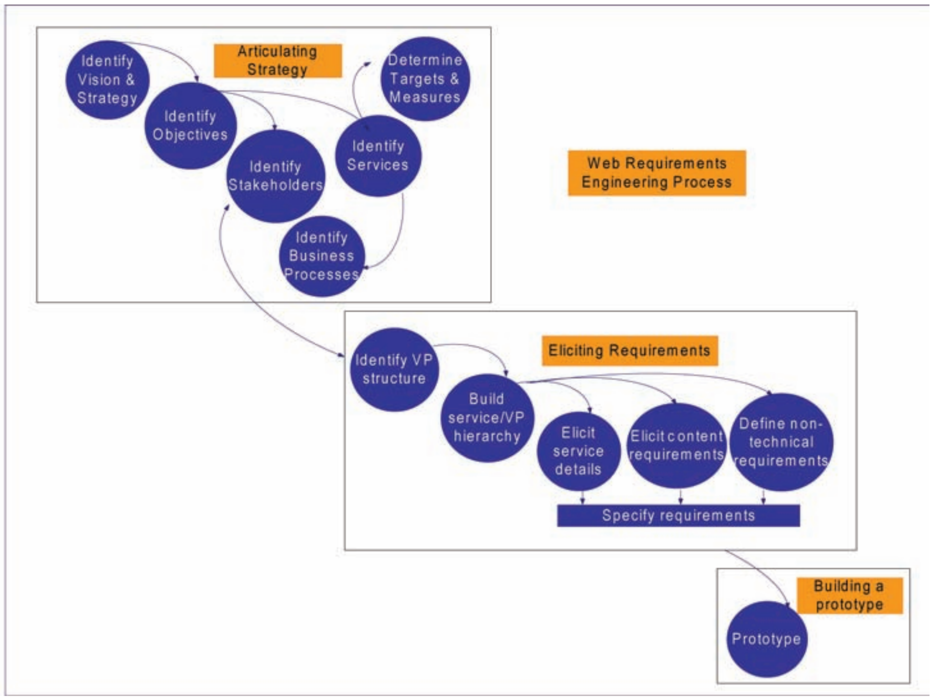
Web applications provide organisations an unprecedented chance to stretch their existence beyond the typical boundaries of an organisation to include customers, trading partners, and suppliers.Little attention has been paid to the process of RE for Web application development, in comparison to other areas of the development process [modelling, design, and coding] (Ginige & Murugesan, 2001). Hence, Web applications can be defined as "applications that tend to be used to integrate and streamline an organisation's business processes beyond organisational (customers, agents, suppliers, others) and geographical borders; provide an organisation with competitive products and services that give it a strategic advantage over its competitors in the marketplace; promote business innovation; and/or improve operational efficiency" (Al-Salem & Abu-Samaha, 2005a).

There is a pressing need in the WE discipline for RE approaches and techniques that (a) take into account the multiplicity of user profiles and the various stakeholders involved [a stakeholder is defined as "anyone who can share information about the system, its implementation constraints or the problem domain" (Potts, Takahashi, & Anton, 1994)]; (b) eliciting overall functionality and the business environment of the Web application; (c) specifying technical and nontechnical requirements of the Web application, and (d) aligning the Web application' requirements to the overall business strategy (Bleistein et al., 2005; Ceri, Fraternali, Bongio, Brambilla, Comai, & Matera, 2003; Ginige & Murugesan, 2001; Kautz & Madsen, 2003; Lowe, 2003; Meldrum & Rose, 2004; Nuseibeh & Easterbrook, 2000; Vidgen et al., 2002). More importantly, a Web application must be developed with an emphasis on how the services of such an application can achieve the business vision and strategy and fulfil the business processes (Haire, Henderson-Sellers, & Lowe, 2001).

eWARE Process

eWARE process can be best perceived as a series of activities grouped into three phases; strategy articulation via BSC, Web application' requirements elicitation via VORD, and prototype building; Figure (1) presents the phases and activities of eWARE. Such a process aims to develop a Web application requirements specification (WRS) document that is aligned with business strategy

Figure 1. The eWARE process



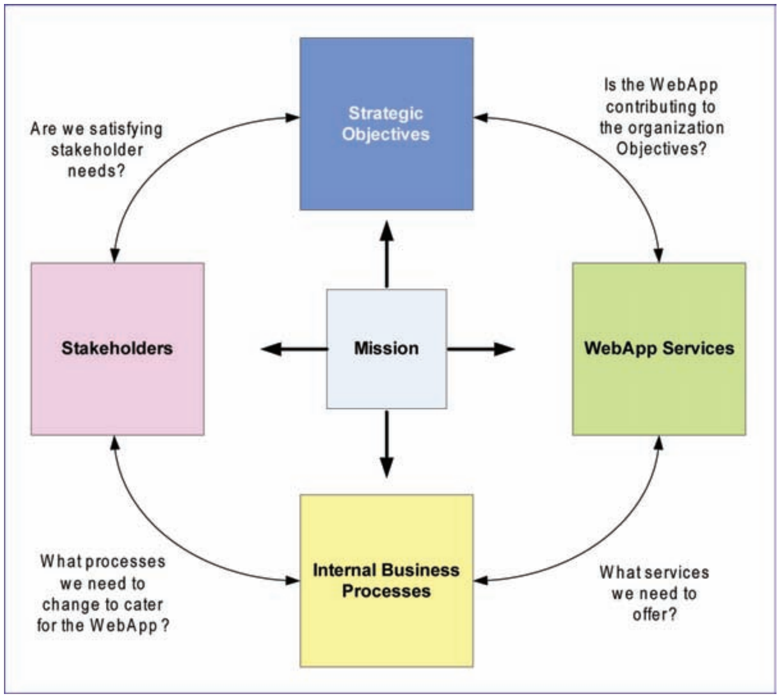
and detailed enough to be used for contractual purposes.

The strategy articulation phase of eWARE can be best thought of as a structure of many layers. The vision of the organisation is at the top of the structure, while the strategic objectives are presented in the next layer of the structure followed by the Web application services. The next layer of the structure contains the measurements and targets for meeting the strategic objectives. The level of detail tends to increase as we move down the structure of the strategy. This articulation of the organisation's vision, objectives, and measurements aims to translate the future vision of the organisation into detailed and prioritised Web application requirements (this will be fully covered in the coming subsections).

The requirements elicitation phase of the eWARE process is used to produce a WRS document based on requirements collected during the strategy articulation phase. Requirements elicitation relies on the identification of the relevant viewpoints (VPs), their sub-VPs, and requirements for each viewpoint (VP). Kotonya and Sommerville (1996) define a VP as anyone who may have some direct or indirect influence on the system/application requirements. Goals and objectives of the different stakeholder groups need to be identified to define success or failure measures for each stakeholder. Moreover, nonfunctional requirements {NFR) need to be identified; these include some of the "-ilities" of the Web application, such as reliability, supportability, maintainability, affordability, and so forth. Finally, in the prototyping phase of the eWARE process, the system/application stakeholders consider the unclear set of requirements, and agree on prototyping the ambiguous requirements to verify them. Moreover, the user interface (UI) and Web site structure are presented in a throw away prototype.

The mentioned WRE phases and activities are perceived to be iterative and incremental in nature where unmet targets are questioned. This cyclic view of the WRE process will trigger the strategy

Figure 2. eBSC perspectives



articulation phase to enter in a feedback loop in order to refine services and change requirements of the Web application in order to enhance the organisation's chance to achieve its set vision and strategy.

Strategy Articulation Phase

As mentioned earlier, the strategy articulation phase of eWARE process aims to align the Web application' requirements to the organisation's business strategy through a process of strategy analysis. eWARE delivers such alignment via eBSC (extended Balanced Score Card). According to eBSC, aligning the Web application' requirements to the business objectives yields four perspectives to focus upon (stakeholders, strategic objectives, internal processes, and Web application services). Figure 2 provides a diagrammatic representation of the perceived relationship between the four perspectives.

Strategic Objectives Perspective

Objectives are statements that clarify what the strategy aims to achieve. Hence, organisations pursue strategies in the belief that, when implemented, they will enable the organisation to better achieve its strategic objectives.

Web Application Services Perspective

The Web application services are the collection of functionality, quality, content, and all what the Web application must provide in order to achieve the strategic objectives of the organisation and to meet the expectations of its stakeholders. This perspective is considered as a precondition to process improvement, stakeholder satisfaction, and business objectives' realisation. Hence, the development team, comprising of requirement engineers and end user representatives, must be empowered to select which services (functionalities) of the Web application will be included, in order to deliver the optimal business solution. Decisions and trade-offs need to be made between new services elicited through the eBSC process, and less important original functionalities that may have to be excluded, being less strategically important.

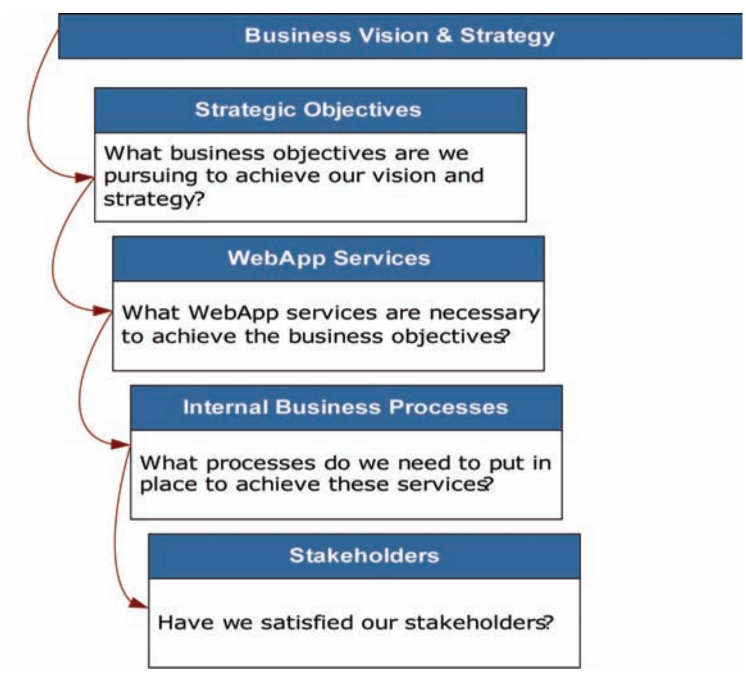
Stakeholders[1] Perspective

The stakeholder perspective is arguably the most important perspective in the Web application development process. As mentioned earlier, a stakeholder is defined by Potts et al. (1994) as "anyone who can share information about the system, its implementation constraints or the problem domain." According to Potts et al. (1994), the list of stakeholders will include end users, indirect users, other customer representatives, and developers. Since a stakeholder is, in essence, a requirements source; it can be an application user, a competitor, or even a third party. Hence, if the stakeholder represents a customer, then the requirements elicitation effort will focus on new customer acquisition, customer retention, and customer profitability. The goal of using eBSC is to classify the organisation's strategy by stakeholder, which will lead to introducing Web application services for each group to meet their strategy or objective. The organisation must determine whom it serves and how their requirements can be met.

Internal Process Perspective

Organisations' activities can be grouped into "business processes" that describe the way work is to be implemented. Some of the organisation's activities will be affected by the introduction of a Web application, since such applications have the potential to significantly change an organisation's work practices and procedures (Ginige & Murugesan, 2001; Pressman, 2004). The internal process perspective focuses on key processes at which the organisation must excel in order to add value to its stakeholders through the Web application.

Figure 3. Web application cause and effect relationships



When designing a score card, the starting point will be asking "what strategies do we have to put in place to satisfy the wants and needs of the key stakeholders?" The inclusion of BSC within the WRE process aims to help clarify, consolidate, and gain consensus around the business–Web application strategy of the organisation, and to translate the business strategy into Web application services (requirements) to ensure that the elicited requirements are strategy focused. Hence, a strategy can be best described as a series of cause and effect relationships that provide a translation from future vision to Web requirements, as shown in Figure (3).

eVORD for Eliciting Web Requirements

The second phase of the proposed WRE process presents the requirements elicitation phase of the Web application development process. eWARE delivers such elicitation via eVORD (extended viewpoint-oriented requirements definition). According to eVORD, templates are created to describe each viewpoint (VP), service, nonfunctional requirement (NFR), and content. As mentioned earlier, Kotonya and Sommerville (1996) define a VP as anyone who may have some direct or indirect influence on the system/application requirements. The VORD requirements engineering process includes activities concerned with VP identification, VP service description, cross-viewpoint analysis to discover inconsistencies, omissions, and conflicts, and developing an object-oriented model of the system/application from the VP analysis. In addition, a VP diagram is used to show the relationships among VPs, while sequence diagrams illustrate the interactions among VPs.

Web Application Viewpoints (WebVPs) Identification and Structuring

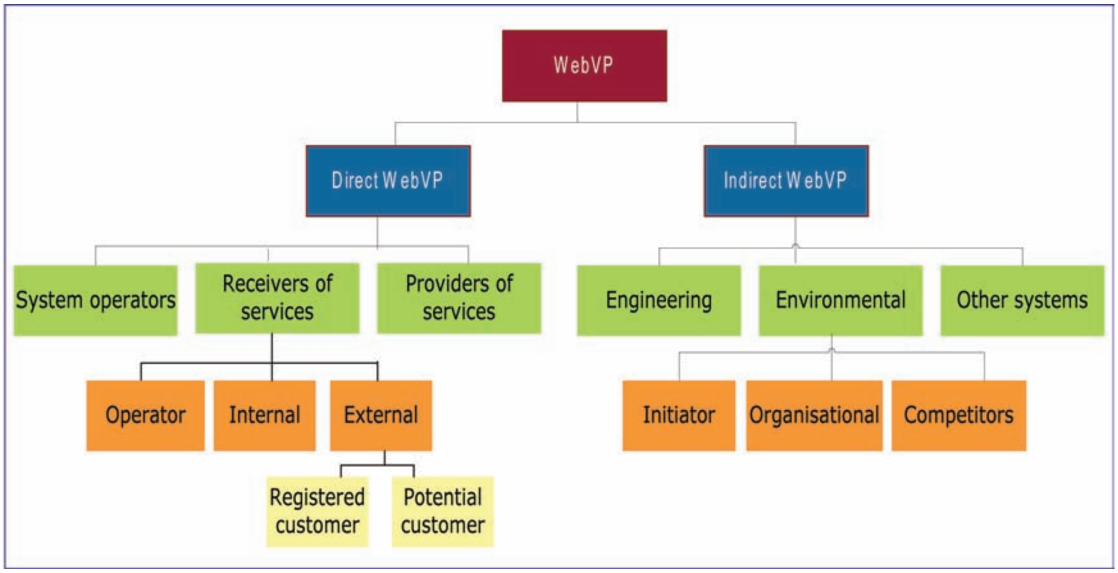
The construction of Web applications involves a great number of stakeholders who have different views of the Web application. These perspectives are partial or incomplete descriptions of the system/application, and reflect the environment in which the system/application will operate in. The integration of multiple views can contribute to augment the overall understanding of the Web application. The authors recommend the use of a new and amended list of VPs for developing Web applications. These WebVPs' abstracts have been identified as a starting point that acts as a template for WebVPs classes and hierarchy. Figure (4) shows a high-level abstract of WebVPs structure.

WebVPs can be classified into *direct VPs* that interact directly with the Web application and fall into two subclasses (receivers and providers of services), and *indirect VPs* that have "interest" in some or all of the services that are delivered by the system but do not interact directly with it; hence, they provide high-level organisational requirements and constraints. Indirect VPs fall into a number of subclasses: *environmental WebVPs*, which reflect the requirements of the business domain, that is, legalisation, localisation, taxation, and competitors; *engineering WebVPs*, which reflect the requirements of the development team, that is, software engineers, team leaders, and creative designers; and *system WebVPs*, which include all existing information systems that the application being analysed needs to interface to, that is, payment systems and supplier systems.

Eliciting Requirements Details

The second step of this phase is concerned with documenting the details of each WebVP (identified in the previous step) and its associated services. For every identified WebVP, a number of templates are used to elicit and specify its requirements. The authors have extended and adapted VORD templates to cater to the particularities of Web applications development (please refer to Al-Salem & Abu-Samaha, 2005a and Al-Salem & Abu-Samaha, 2005b for more details).

Figure 4. Abstract of WebVPs structure



Documenting Requirements

The objective of the requirements process is to deliver a requirements specification document that defines the system/application to be developed (Sawyer, Viller, & Sommerville, 1997). This document is used for contractual purposes, and can be used as a basis for facilitating a competitive tendering for the system/application design and implementation (IEEE, 2004). The authors have enhanced the typical software requirements specification (SRS) document to reflect the changes introduced to eVORD and eBSC, as depicted in Figure (5).

FUTURE WORK

The domain of RE, in general, and WRE, in particular, is evolving with the ever-changing contexts of software engineering and information systems development projects. Despite the availability of many requirements, engineering methods, processes, techniques, and tools, such artefacts are in need of constant extensions and enhancements to bring such artefacts to the changing contexts of the development projects. The presented eWARE method is an extension of two existent methods used to align requirements of a Web application to the organisation's business strategy. eWARE needs to be tested further in different industrial settings to validate the applicability of the method. As well, eWARE, like many other RE methods, needs to be supported through the development of a computer aided software engineering (CASE) tool to facilitate the generation of the WRS document. Compared to similar WRE methods (Bleek et al., 2002; Bleistein et al., 2004; Bolchini & Paolini, 2004; Gordijn et al., 2000; Meldrum & Rose, 2004), eWARE provides its users with a number of benefits: it extends the BSC approach to help with the formulation of Web application strategy as a stage in the WRE process in advance to requirements elicitation; it provides a prioritisation framework synchronised with business strategy; it extends VORD to elicit requirements for Web applications; and it creates a WRS document that specifies both the business strategy and requirements for the Web application. Such advantages proved to be valuable in Web applica-

tion development projects, as Web applications are different in many aspects when compared to other applications. The differing characteristics of Web applications can be summarized as diverse and volatile requirements, vast and unknown end users, multiple stakeholders, adaptable architecture, short development life cycle, high visibility, heavy content, integration with backend databases and third party applications, Web applications' relevance and direct effect on business, and multidisciplinary development team.

CONCLUSIONS

There are two general opinions on whether current software engineering methods and techniques are applicable to face the challenges of developing a Web application. One opinion advocates the need for a new "software engineering" discipline that handles the Web application particularities (Ginige & Murugesan, 2001, Murugesan, 1999; Murugesan, Deshpande, Hansen, & Ginige, 1999). In contrast, the other opinion believes that current software engineering methods, tools, and techniques are applicable to Web application development. For example, McDonald and Welland (2001) recommended developing new methods, techniques, and approaches to address the challenges of developing Web applications in order to increase the possibility of their success. This implies the need for a new breed of WRE methods, tools,and working practices. In contrast, Pressman (2004) argues that Web applications are a natural evolution of existing applications/systems offering a solution to classical problems exhibited by previous information systems (IS). The authors of this chapter hold a middle position in between these two opinions. The authors perceive Web applications as a natural evolution of "traditional" information systems, yet they believe that such applications possess special characteristics that need to be provided for by the "traditional" RE method(s). Hence, existing RE methods are considered valid for WRE, though they need to be enhanced and extended to cater to the distinguishing features of Web applications.

The chapter has presented a WRE approach that enables businesses to develop/procure Web application(s) capable to achieve the organisations' business strategic objectives, and to effectively harness their business processes. The combination of BSC (Kaplan & Norton 1993, 1996a & b) and VORD (Kotonya & Sommerville 1996) within eWARE process provides the development team with the ability to translate strategy into Web application requirements and to incorporate views from different complementary perspectives. Hence, eWARE is a Web-specific RE process to cope with the complex aspects of requirements elicitation, alignment, and specification for Web applications development/procurement. eWARE views Web applications as organisational initiatives and as such, it takes into account the need to address strategic objectives, business processes issues, requirements details of services, NFR, and integration with other systems.

KEY TERMS

Balanced Score Card (BSC): "A multidimensional framework for describing, implementing and managing strategy at all levels of an enterprise by linking objectives, initiatives and measures to an organisation's strategy" (Kaplan & Norton, 1993, 1996 a & b)

eWARE (extended Web application requirements engineering): "A strategy-focused requirements engineering method used to align Web application requirements to business strategy and to elicit legal, technological, business, marketing and content requirements"

A Requirement: "A condition or capability that must be met or fulfilled by a system to satisfy a contract, standard, specification, or other formally imposed documents." (IEEE Standard, 610,12-1990)

Requirements Engineering (RE): "The process of discovering that 'purpose' by identifying stakeholders and their needs, and documenting them in a form that is amenable to analysis, communication, and subsequent implementation" (Nuseibeh & Easterbrook, 2000)

Stakeholder: "Anyone who can share information about the system, its implementation constraints or the problem domain, including end users, indirect users, other customer representatives and developers" (Potts et al., 1994)

Viewpoint (VP): "Any one who may have some direct or indirect influence on the system requirements" (Kotonya & Sommerville, 1996)

Viewpoint Oriented Requirements Definition (VORD): "A software requirements engineering approach used to organise both the elicitation process and the requirements themselves into viewpoints" (Sommerville, 1995)

Web Business Application (WebApp): "An application that tends to be used to integrate and streamline an organisation's business processes beyond organisational (customers, agents, suppliers, others) and geographical borders, to provide an organisation with competitive products and services that give it a strategic advantage over its competitors in the marketplace

to promote business innovation and/or to improve operational efficiency" (Al-Salem & Abu-Samaha: 2005a)

ENDNOTE

[1] Throughout eWARE, a stakeholder /viewpoint is used interchangeably.

ABSTRACT

This chapter presents a comprehensive logic programming framework designed to support intelligent composition of Web services. The underlying model relies on the modeling of Web services as actions, each described by a logic programming theory. This view allows the use of logic-based planning to address the Web service composition problem, taking advantage of the fact that logic-based planning enables the elegant introduction of a number of extensions and generalizations (e.g., dealing with incomplete knowledge and preferences). The theory describing each Web service is encoded as a logic programming module, and different semantics are allowed within different modules, thus better reflecting the practical use of different service description formalisms and ontologies.

INTRODUCTION

One of the main goals of the Semantic Web initiative (Berners-Lee, Hendler, & Lassila, 2001) is to extend the existing Web technology to support the development of intelligent agents, which can *automatically* and *unambiguously* process the information available in millions of Web pages. This led to numerous works on *Web services* and *Web service composition*. The primary goal of Web service composition is to determine an appropriate sequence of Web services to accomplish a user goal. The majority of the existing proposals dealing with Web service composition build on the principle of viewing Web services as *actions*, thus, representing the Web service composition problem as a *planning problem* that can be addressed using existing *planning* techniques. A second popular approach to Web service composition relies on techniques developed in the area of workflow development. The survey by Rao and Su (2004) provides a good overview of various proposals for Web service compositions.

McIlraith and Son (2002) propose to use *GOLOG* (Levesque, Reiter, Lesperance, Lin, & Scherl, 1997), a logic programming based language, for Web service composition. In such a proposal, each Web service is translated to a primitive action. GOLOG provides control-flow constructs, such as **if-then-else**, **while-do**, **sequence** (denoted by '**;**'), **procedure**, and **test** (denoted by '**?**'), which can be used to combine the primitive actions into programs. The resulting programs can be provided to a *GOLOG* interpreter for finding the sequence of Web services that need to be executed to achieve the goal of the user. Alternatively, the program can be given to an execution monitoring module, for direct execution. Sufficient conditions for a successful execution of a program are also provided. This direction of work has been adopted by Au, Kuter, and Nau (2005), Kuter, Sirin, Nau, Parsia, and Hendler (2005), and Wu, Parsia, Sirin, Hendler, and Nau (2003), where SHOP2, a hierarchical planning system, is used as the underlying system for automatic Web service composition. The latter work also addressed an important aspect of Web service composition, namely, the problem of incompleteness of information in Web service composition, by adding to the planning algorithm a module for gathering information during the planning process.

Viewing Web service composition as high-level planning is not only natural, but also advantageous for different reasons:

- AI planning has made remarkable progress in the last 10 years, and several robust and scalable planning systems have been developed and are available for use, such as *FF* (Hoffmann & Nebel, 2001), *SHOP* (Nau, Cao, Lotem, & Muñoz-Avila, 1999), SAT-based planners (Kautz & Selman, 1996), and logic programming based planners (Lifschitz, 1999). All these planners can be used as the backbone in the development of systems for Web service composition with an architecture similar to the one described by McIlraith and Son (2002).
- AI planning allows the Semantic Web research community to focus on the development of Web service representation and reasoning languages and tools for translating Web service representation into a planning language.

Indeed, this view of Web service composition has been embraced by many researchers, and a number of tools have been proposed, for example, translators to map Web services encoded using DAML-S or OWL-S to PDDL (PDDL Technical Committee, 1998), a well-known planning language used by many planning systems.

While the use of planning in Web service composition is advantageous, there are a number of issues that need to be addressed before this approach can be widely applied. The first problem, which can be termed as the *service selection problem*, derives from the huge number of available services that can be used to achieve the same goal. The second problem lies in the lack of information in service composition, which imposes additional requirements on the planning system, such as the ability to plan with incomplete knowledge and to handle knowledge producing actions. The third problem centers on the *quality* of the composed service, which can be translated into the problem of planning with preferences, an area of research that has only recently attracted interest from the planning community. The fourth problem derives from the fact that each Web service is often encoded within an ontology or a knowledge base, whose semantics is specified by the service provider, and hence, might be different from service to service. A final problem, that has been recognized very early in the development of the Semantic Web (Berners-Lee & Fischetti, 1999; Berners-Lee et al., 2001), is the need for mechanisms to encode *rules*, for example, rules for the description of Semantic Web services and business rules interchange in e-commerce applications.

Answer set programming (ASP) is a declarative programming framework, originally proposed by Marek and Truszczynski (1999) and Niemelä (1999). To solve a problem in ASP, we translate it into a logic program, whose answer sets correspond one-to-one to solutions of the original problems. ASP has found its way in several real-world applications, for example, diagnosis of components of the space shuttle (Balduccini, Gelfond, & Nogueira, 2006). ASP has been widely adopted in the area of reasoning about actions and planning; it has been applied to solve various forms of planning, such as classical planning, conformant planning, and conditional planning (e.g., Son, Tu, Gelfond, & Morales, 2005; Tu, Son, & Baral, 2006). ASP has been used to incorporate various forms of domain knowledge in planning (Son, Baral, Tran, & McIlraith, 2006a) and to construct plans satisfying multidimensional preferences (Son & Pontelli, 2006). This existing body of knowledge provides the foundations for the development of a logic programming-based framework for Web service composition that addresses all but the problem of dealing with Web services encoded in heterogeneous knowledge bases. This last problem is becoming more and more critical with the development of distinct standards and ontologies for Web service encoding and the wider availability of Web services in the Internet. *This problem will be our main concern in this chapter.*

In this chapter, we propose a logic programming framework for reasoning with distributed heterogeneous knowledge bases that contain rules and facts, that is, we concentrate on the fourth problem faced by the Web service composition problem. Our specific objectives are:

1. The design of a theoretical framework for *reasoning with heterogeneous knowledge bases*, which can be combined with logic programming-based planners for Web service composition. This framework supports:
   a. The interoperation between knowledge bases encoded using different rule markup languages, and
   b. The development and integration of different components that reason about knowledge bases.
2. The development of a prototype of the proposed framework.

The chapter is organized as follows. We start by briefly reviewing the representation of Web services and rules in the Semantic Web, the foundation of logic programming and answer set planning, the use of answer set planning in Web service composition, and discuss the challenges faced by the current architecture for Web service composition. In the successive sections, we describe the main contribution of this chapter, a framework for reasoning with distributed heterogeneous knowledge bases, and its implementation. Finally, we relate our work to other proposals and provide conclusions and indications for future developments.

WEB SERVICES AND LOGIC PROGRAMMING

We begin with a review of the common elements of Web services and the RuleML language, and the basics of logic programming. We then discuss how logic programming can be used in Web service composition and discuss the issues that need to be addressed.

    </operation>
```

Web Services and RuleML

Many Web service description languages have been proposed (e.g., www.w3c.org). The most recent proposal, WSDL 2.0 (Chinnici, Moreau, Ryman, & Weerawarana, 2007), describes a Web service in terms of

- The kinds of messages that the service will send/ receive (using the **types** element).
- The functionalities of the service (**interface** element).
- The way to access the service (**binding** element).
- The location of the service (**service** element).

In essence, a service can be viewed as a collection of subroutines (or functions), and it is described by a valid WSDL 2.0 document. If a service requesting agent would like to use a service, it needs to place a request with the proper parameters. For example, Figure 1 shows an excerpt from Booth and Liu (2005), used to define the 'checkAvailability' function for a hotel reservation service, which takes three parameters (i.e., checkInDate, checkOutDate, and roomType) and returns either an error message indicating that the date is improper (invalidDataError), or a number indicating the number of available rooms (checkAvailabilityResponse).[1]

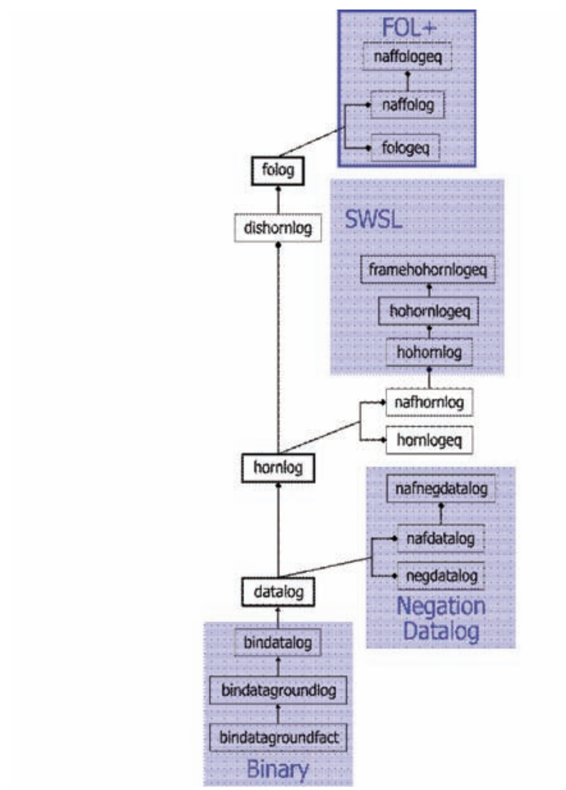
Many of the existing Web services are described within some ontology (e.g., an OWL description). More and more are associated with a set of rules (also called a *knowledge base*). Such a knowledge base is often written in one of the variants of the RuleML markup language.

The RuleML initiative[2] is a response to the need of a common XML-based rule markup language, which has precisely defined semantics and enables efficient implementations. In recent years, a significant amount of work has been devoted to develop knowledge representation languages suitable for the task, and a variety of languages for rule markup have been proposed. The initial design (Boley, Grosof, Sintek, Tabe, & Wagner, 2002) included a distinction (in terms of distinct DTDs) between *reaction* rules and *derivation* rules. The first type of rules is used for the encoding of event-condition-action (ECA) rules, while the second is meant for the encoding of implicational and inference rules.

The derivation rules component of the RuleML initiative has originated a family of languages. Figure 2, from Hirtle and Boley (2005), shows the most commonly referred languages; observe that Datalog plays the role of a core language, with simplified versions (e.g., unary and binary Datalog) developed for combining RuleML with OWL (as in SWRL) (Horrocks, Patel-Schneider, Boley, Tabet, Grosof, & Dean, 2004). Various sublanguages have been created to include features like explicit equality (e.g., fologeq), negation as failure (e.g., naffolog), and Hilog layers (e.g., hohornlog). Specific instances of RuleML for handling different aspects of Web services have been proposed (The Policy RuleML Technical Group, 2004).

Kifer, de Bruijn, Boley, and Fensel (2005) argue that any realistic architecture for the Semantic Web must be based on various independent but interoperable languages, one of them being the logic programming language with negation-as-failure. The use of rule-based languages requires the coexistence of different languages with different semantics and associated reasoning mechanisms, and the need to integrate reasoning across these languages. The need for these languages and their interactions have been extensively discussed (e.g., Kifer et al., 2005; May, Alferes, & Amador, 2005) and it is at the foundation of the most recent work of the Rule Interchange Format working group. It is also important to note that many of the sublanguages of RuleML have been implemented either through translators, for example, GEDCOM (Dean, 2001), which translates to XSB Prolog and JESS, or using independent inference engines, for example,

Figure 2. RuleML language modularization



- j-DREW (Spencer, 2002), a top-down engine for RuleML,
- DR-Device (Bassiliades, Antoniou, & Vlahavas, 2006), an engine supporting defeasible logic and both strong and default negation, and
- CommonRules (Chan & Grosof, 1999), a bottom-up engine for the Datalog sublanguage.

It should be noted that RuleML, WSDL 2.0, and the other markup languages employed when dealing with Web services are simply representation languages. An agent making use of Web services can be developed in any programming language (e.g., JAVA, C++, Perl, etc.). For this reason, previous proposals for Web service composition assume the existence of translators which map Web service descriptions to representations that are more adequate for manipulation and reasoning. For example, McIlraith and Son (2002) map Web service descriptions to situation calculus, while other recent proposals make use of encodings in PDDL; for example, translators of Web service descriptions (in DAML-S) to PDDL (McDermott, Dou, & Qi, 2002).

For the purpose of this chapter, we will assume the existence of translators that map Web service descriptions into a logic programming representation. Many of such tools are already available on the Web (e.g., Rainer, 2005).

Logic Programming

We will consider a logic programming language $\langle \Im, \Pi, \vartheta \rangle$, where $\Im$ is a denumerable collection of function symbols, $\Pi = \Pi_u \cup \Pi_d$ is a denumerable collection of predicate symbols, and ϑ is a collection of variables. Π_u are called user-defined predicates, while $\prod_d$ are called built-in predicates. We will assume that $\Pi_u \cap \Pi_d = \varnothing$. We will denote with $ar(\alpha)$ the arity of the symbol $\alpha \in \Pi \cup \Im$. We typically assume that Π_d contains at least the predicates assert, retract, and model.

A *term* is either a variable, an element of $\Im$ of arity 0 (i.e., a constant), or an expression of the form $f(t_1,\dots,t_n)$ where $f \in \Im$, $ar(f)$=n and $t_1,\dots,t_n$ are terms. We will say that a term t is ground if it does not contain variables. We will denote with H_P the Herbrand universe for this language, that is, the set of all ground terms.

An *atom* is a formula of the form $p(t_1,\dots,t_n)$ where $p \in \Pi$, $ar(p)$=n and $t_1,\dots,t_n$ are terms. The atom is ground if $t_1,\dots,t_n$ are ground. A *qualified atom* is a formula of the form $t{:}A$ where t is a ground term (called the *label* of the qualified atom) and A is an atom. In particular, if the predicate p of an atom belongs to Π_d, then the atom can only appear qualified in a rule. A literal is an atom, a qualified atom, or a formula *not* A, where A is an atom/qualified atom. *not* A is also referred to as a negative literal. We will denote with B_P the Herbrand base for this language (i.e., the set of all ground atoms). For an atom (qualified atom, negative literal) l, we denote with $\pi(l)$ the predicate symbol used in l.

A general rule is of the form

$A \leftarrow B_1,\dots,B_k$ (1)

where A is an atom and $B_1,\dots,B_k$ are literals. Intuitively, a Rule (1) states that if the literals $B_1,\dots,B_k$ are true, then we can conclude that A is also true. We view interpretations and models as subsets of B_P. For an atom A, the literal A (resp. *not* A) is true in a model M if $A \in M$ (resp. $A \notin M$).

Depending on the type of programs we wish to represent, different restrictions can be imposed on the rules:

a. **Datalog:** The B_i's in Rule (1) can be only atoms/qualified atoms and the terms used in the literals can be only variables or constants (i.e., of arity 0).
b. **Ground datalog:** The B_i's in Rule (1) can only be atoms/qualified atoms, and the only terms allowed are constants.
c. **Ground binary datalog:** The rules satisfy the conditions of Case (b), and in addition we require all predicates used to construct atoms to have arity at most 2.
d. **Datalog with negation:** The rules have the format as in Case (a) but negative literals (*not* A) are allowed in the body of the rule.

We will refer to a rule as a Ξ-rule (where Ξ is Datalog, ground Datalog, binary Datalog, etc.) to denote a rule that meets the corresponding requirements. A Ξ-program is a collection of Ξ-rules. Given a rule r, we denote with $used(r)$ the set of ground terms t such that t is a label of a qualified atom in r. Given a Ξ-program, we denote with

$used(P) = \{\ t \mid \exists\ r \in P,\ t \in used(r)\ \}$.

We also introduce

def(P) = { p | $p \in \Pi$, *ar*(p)=k, $\exists r \in P$. $\exists\, t_1,\ldots,t_k$, *head*(r) = $p(t_1,\ldots,t_k)$ }.

Intuitively, a Ξ-program encodes a knowledge base, whose semantics is defined by a class of models satisfying certain properties. It should be noted that the semantics of a program might be defined in different ways and depends on the program type. For Datalog programs, the least fixpoint semantics can be used (van Emden & Kowalski, 1976). However, for Datalog with negation programs, the well-founded (Van Gelder, Ross, & Schlipf, 1991) or the answer set semantics can be used (Gelfond & Lifschitz, 1988).

Planning in Logic Programming and Web Service Composition

A planning problem is specified by a domain, with its properties (called *fluents*) and *actions* with their preconditions and effects, a specification about the initial state of the world, and a formula describing the final state (*goal*). The objective is to determine a sequence of actions that can transform the initial state into a state satisfying the goal.

Logic programming under the answer set semantics was first used in planning by Subrahmanian and Zaniolo (1995) and is now known as answer set planning (Lifschitz, 2002). Answer set planning has gained popularity thanks to the development of fast answer set solvers (e.g., Smodels, Simons, Niemelä, & Soininen, 2002 and DLV Eiter, Leone, Mateis, Pfeifer, & Scarcello, 1998). Since our intention is to use logic programming for Web service composition, following the AI planning approach, we will give a brief overview of answer set planning by illustrating its key ideas through an example. As noted earlier, existing tools can be adapted to translate Web service descriptions into the representation discussed in this chapter.

Answer Set Planning

Let us consider the classical AI problem of going to the airport (McCarthy, 1959). In this problem, we have an action, named *drive_home_airport*; in the initial state, we are at home and have a car. We know that driving will bring us to the airport and our goal is to go be at the airport.

In answer set planning, this problem is encoded by a Datalog with negation program that consists of the different groups of rules described below. In each of these rules, T denotes a number between 0 and a predefined constant length, indicating the maximal length of the plan that we wish to compute. The rules

action(drive_home_airport) ←
fluent(at_home) ←
fluent(at_airport) ←
fluent(car_available) ←

specify the fluents and the actions of the domain. The rules

false← not holds(at_home,T), occ(drive_home_airport), T)
false← not holds(car_available,T), occ(drive_home_airport), T)

encode the precondition under which the action drive_home_airport can be executed. They state that the action drive_home_airport can only occur at the time T if at_home and car_available are true at the time T. The rules

holds(at_airport,T+1)←occ(drive_home_airport, T)
holds(neg(at_home),T+1)←occ(drive_home_airport, T)

say that if the drive_home_airport action occurs at the time T, at_airport and at_home will be true and false, respectively, at the time T+1. The two rules

occ(drive_home_airport,T)←not not_occ(drive_home_airport,T)
not_occ(drive_home_airport,T)←not occ(drive_home_airport,T)

are often referred to as *generation rules,* and are used to generate action occurrences. Intuitively, they state that the action either occurs or not. The rules

holds(at_airport,T+1)←holds(at_airport, T),

not holds(neg(at_airport), T+1)

holds(neg(at_airport),T+1)←holds(neg(at_airport), T),

not holds(at_airport, T+1)

known as *inertial rules*, encode the fact that a fluent normally does not change its value. (We omit the rules for at_home and car_available for brevity.)

Finally, the initial state is encoded by a set of facts of the form

holds(neg(at_airport),0) ←

holds(at_home, 0) ←

and the goal is expressed by the rule

false←not holds(at_airport,length)

Each answer set of the above program corresponds to a plan achieving the goal at_airport. For example, for length=1, the program yields an answer set corresponding to the plan [drive_home_airport]. For more on answer set planning, the interested reader is referred to Lifschitz's (2002) work.

Answer Set Planning and Web Service Composition

Answer set planning can be used for Web service composition, but it requires some modifications and extensions. For example, the functions of the hotel reservation Web service (Figure 1) can be encoded by the following actions:

action(checkAvailability(DateIn,DateOut,RoomType))←date(DateIn),

date(DaeOut),

type(RoomType)

action(makeReservation(DateIn,DateOut,RoomType))←date(DateIn),

date(DaeOut),

type(RoomType)

It is reasonable to consider the two following fluents:

- available: there are some rooms available
- reserved: the reservation has been successful

They can be encoded as follows

fluent(available)←

fluent(reserved)←

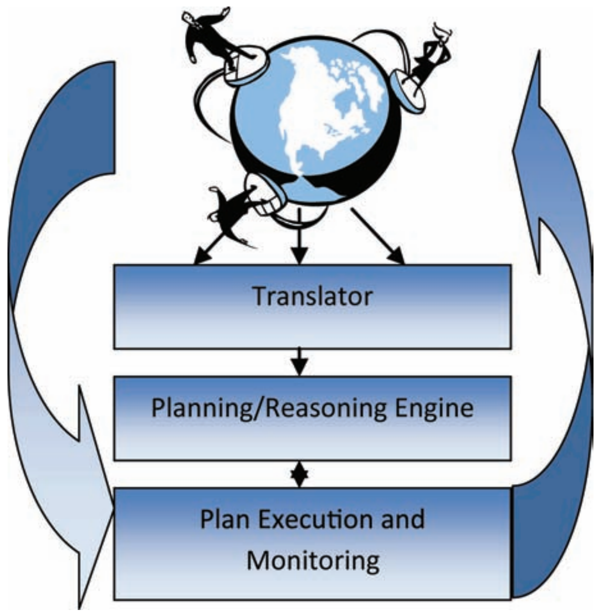
The effect of the action checkAvailability is different than the effect of the action makeReservation. The execution of checkAvailability is *either* available *or* ¬available, while the execution of makeReservation is reserved. The first action, called *knowledge producing action*, does not change the state of the world (it does not alter the number of available rooms) while the second one does (it reduces the number of available rooms by 1).

Knowledge producing actions are often needed when a reasoner does not have complete information about the state of the world. For example, an agent that uses the above service to place a reservation often does not know whether or not the hotel would have a room. In other words, neither available nor ¬available is true in the initial state. The agent knows about the value of available (or ¬available) after the execution of the action checkAvailability. In our previous work (i.e., Son et al., 2005; Tu, Son, & Baral, 2006), we discuss the use of logic programming in reasoning and planning with knowledge producing actions and incomplete information. We also extended answer set planning to incorporate different types of domain knowledge and user preferences (Son, Baral, Tran, & McIlraith, 2006b; Son & Pontelli, 2006).

Current Architecture and Challenges

The techniques developed so far can be used in the implementation of a Web service composition framework similar to other AI-planning Web service composition frameworks (Figure 3). The basic components of this approach are:

Figure 3. Schematic architecture



- A *translator* which reads Web service descriptions and translates them into an adequate logic programming theory (e.g., a Datalog with negation program).
- A *reasoning/planning engine* which accepts the output of the translator and creates a plan that achieves the goal of the service composition problem.
- An *execution and monitoring* module which is responsible for the execution of the plan.

Architectures analogous to the one depicted in Figure 3 have been successfully implemented, for example, in the development of systems for Web service composition of bioinformatics Web services (e.g., (Pan, Tu, Pontelli, & Son, 2004)). In this application, the results of the translation are Datalog, Datalog with negation, or a similar variant language. The reasoning/planning engine employs the answer set semantics for this program. Furthermore, it is assumed that all necessary information has been incorporated into the encodings of the corresponding services. Although the resulting system is adequate for the mentioned application, the new developments in Semantic Web present two technical challenges to this architecture.

The first problem lies in the fact that knowledge (and hence, Web services) often comes with *reasoning rules*, that were not the focus of earlier Web service description languages, and hence this aspect has not been addressed in previous implementations. The second challenge is the need to consider different semantics embedded in the encoding of a Web service, since the underlying semantics of various RuleML knowledge bases are specified by the knowledge engineers and not by the application developers. In dealing with this problem, we can identify a number of issues that need to be addressed:

1. *Reasoning within one knowledge base:* Being able to reason within a knowledge base implies the ability to interoperate with a computational framework capable of handling the type of knowledge present in the knowledge base (e.g., a Prolog system for hohorn rules, a Datalog system for Datalog rules).

2. *Reasoning across different knowledge bases:* The capability of combining knowledge is essential for intelligent agents (e.g., this is necessary in the context of services composition). This requires
    a. The ability to exchange inference results between different knowledge bases (e.g., the interoperability problem between rules and OWL described by Kifer et al. [2005]);
    b. The ability to combine reasoning results produced by different reasoning engines; and
    c. The ability to properly scope the reasoning w.r.t. a specific knowledge base (e.g., the scoped inference issue described by Kifer et al. [2005]).
3. *Utilizing available knowledge:* This requires the ability to use the results produced by different reasoning processes in the construction/implementation of complex Semantic Web applications.

A Motivating Example

Let us illustrate some of these issues within an example, drawn from the field of bioinformatics. This application domain is particularly interesting with respect to the issue of Web service composition; in recent years a large number of Web services have been developed, and they rely on a large collection of heterogeneous (and often redundant) ontologies and knowledge bases.

The problem at hand is to obtain reliable functional annotation, according to the Gene Ontology (Gene Ontology Consortium, 2007), of the proteins coded by the genes present in the genome of an organism. The input is represented by the NCBI RefSeq id of a genome (i.e., an id of the form *NC_xxxx*). It has been observed that functional annotations retrieved by AmiGO (the query system to the Gene Ontology Database) are occasionally unreliable (e.g., Andorf, Dobbs, & Honavar, 2007). In particular, it has been observed that some incorrect annotations in the Gene Ontology are characterized by a selection code equal to reviewed computational analysis (RCA). We consider the following services and knowledge bases:

- **NCBI GenBank Genome-to-Protein Search:** This service expects as input the RefSeq of a genome, and produces as results the NCBI ids of the proteins coded by the genes in the considered genome;
- **Protein Class Ontology:** Gene Ontology includes a taxonomy of functional classification of proteins (e.g., its OBO encoding can be found in “Gene Ontology, Edit 1.101, ” [2007]). The taxonomy can be directly encoded in Datalog; sample rules extracted are:

```
id(0016301)
name(0016301, ‘kinase activity’)
namespace(0016301,molecular_function)
is_a(0016301,0016772)
...
id(0004672)
name(0004672,’protein kinase activity’)
alt_id(0050222)
xref(reactome(4030))
is_a(0004672,0016301)
is_a(0004672,0016773)
...
```

Ontological reasoning allows us, for example, to discover subclasses and superclasses of a given one.

- **Functional Annotation Service:** The input is an id of a protein. If the protein belongs to a class whose functional annotation is not RCA, then the annotation is retrieved from the Gene Ontology annotation database and returned. Otherwise, the annotation is extracted from the UniProt database (and returned in UniProt format). The semantics of this service requires the use of more complex rules (encoded in RuleML using the nafdatalog language). Some of the Datalog with negation rules are:

suspect(ProteinClass) ←
amigo:evidence_code(ProteinClass,rca)
classification(ProteinClass,
FuncAnnotation,go)←
amigo:is_a(ProteinClass,FuncAnnotation),
not suspect(ProteinClass)
classification(ProteinClass,FuncAnnotation,
uniprot) ←
suspect(ProteinClass),
interpro2go:entity_xref(ProteinClass,X), uni
prot:is_a(X,FuncAnnotation)

- **Gene Ontology to InterPro Ontology Mapping:** This mapping, expressed in a ground Prolog facts database is available at the "OBO download matrix" (2007).

Let us assume that the initial state includes the RefSeq NC_003075 (Arabidopsis thaliana chromosome 4) and we are interested only in proteins that are enzyme inhibitors. The genome includes 4,817 coding genes. One of the proteins generated is AT4G00080. The Gene Ontology can be used (through a transitive closure of the is_a relationship) to determine that the protein belongs to the desired class. Accessing the functional annotation, we discover that the protein is annotated as a pectinesterase inhibitor (GO:0046910), but it is RCA. This means that the desired annotation will be extracted from UniProt, and this returns an annotation IPR006501. The mapping between ontologies contains the fact

metadata_db:entity_
xref('GO:0046910','IPR006501')

This will eventually produce the same Gene Ontology annotation.

A FRAMEWORK FOR INTEROPERATION AND COMPOSITION

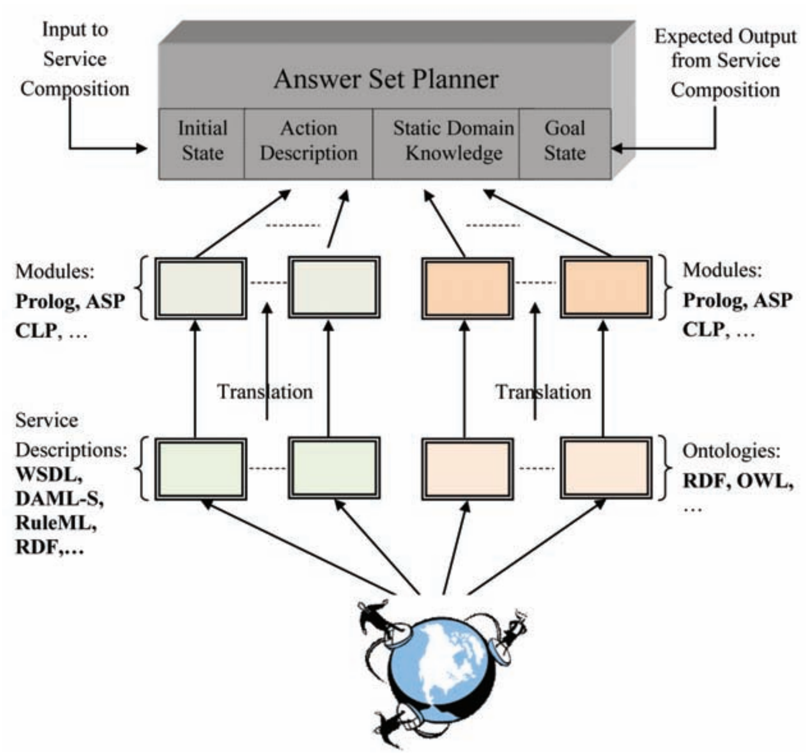
In this section, we describe our framework for interoperation and composition of distributed heterogeneous knowledge bases. We begin with an overview of the approach. We then present the architecture of the component needed to address the challenges faced by the current Web service composition methodology. The precise syntax and semantics of the framework are discussed next.

Overview of the Approach

The objective is to provide a formal logic-based framework that allows the development of the planning/reasoning component of Figure 3. The approach we follow is intuitively depicted in Figure 4. The framework is assembled as a collection of modules, each containing a logic programming theory, potentially requiring a different semantics (e.g., datalog/pure prolog, constraint logic programming, answer set programming, etc.) The modules are the result of a logic programming encoding of the semantics of the Web services description (left side of Figure 4) and of the underlying associated static knowledge (e.g., ontologies – shown on the right in Figure 4). The framework assumes the possibility of dependencies between the different modules, for example, ontologies can be hierarchically defined.

The answer set planner is encoded using a modular view of the action domain. Each service is represented by a logic programming module, which exports the description of the service as an action; in particular, the module exports the description of the action in terms of its executability conditions (predicate executable) and its dynamic effects (predicate causes). For example, in the case of the functional annotation service mentioned previously, these predicates could be defined as:

Figure 4. Framework architecture



executable([have_protein(X), have_protein_class(C)])
causes(go_classification(X,C)) ←
have_protein(X),
have_protein_class(Class),
classification(Class,C,go)
causes([validated_annotation,uniprot_classification(X,C)]) ←
have_protein(X),
have_protein_class(Class),
classification(Class,C,uniprot)

The planner will use these predicates to develop plans, for example, using rules like:

holds(F,T+1) ← action(A),
occ(A,T),
A:causes(F),
A:executable(List),
holds(List,T)

where the execution of the action A requires recovering from the corresponding module (which we assume has the same name as the action) the executability conditions (which are tested in the state of the world at time T) and the effects of the action.

Static causal laws will be employed to allow the planner to make use of background knowledge used by the Web services (e.g., ontologies, databases). For example, the protein class ontology, imported as a Prolog module, would allow us to derive rules like:

holds(have_protein_class(C),T) ←
holds(have_protein_class(C1),T),
gene_ontology:is_a(T1,T)

Architecture

The approach adopted in this work relies on the use of a core logic programming framework to address the issues of integration and interoperation. In particular, the spirit of our approach relies on the following beliefs:

- The natural semantics of various languages for Web service description, ontology description, and various levels of the RuleML deduction rules hierarchy can be naturally captured by different flavors of logic programming.
- Modern logic programming systems provide foreign interfaces that allow declarative interfacing to other programming paradigms.

The idea is to combine the *ASP-Prolog* framework of Elkhatib, Pontelli, and Son, (2006)—which allows CIAO Prolog (Bueno, Cabeza, Carro, Hermenegildo, López-García, & Puebla, 1997) programs to access and modify modules containing answer set programming (ASP) code (Niemelä, 1999)—with the notation for modularization of answer set programming of Answar, Baral, and Tari (2005) and Baral, Dzifcak, and Takahashi (2006). The result is a logic programming framework, where modules responding to different logic programming semantics (e.g., Herbrand minimal model, well-founded semantics, and answer set semantics) can coexist and interoperate. The framework provides a natural answer to the problems of use and interoperation of RuleML and other Web service semantic descriptions described earlier. The overall structure is depicted in Figure 4. Most of the emphasis is on the use of answer set programming to handle some of the RuleML sublanguages (e.g., datalog, ur-datalog, nafdatalog, and negdatalog), even though the core framework will naturally support most of the languages (e.g., hornlog and hohornlog).

The problems mentioned in the previous section are addressed by the proposed framework as follows:

- *Issue 1*: CIAO Prolog offers direct access to a collection of modules that support different forms of logic programming reasoning, for example, traditional Prolog, constraint logic programming (over finite domains and reals), fuzzy Prolog, and a declarative ODBC interface. In addition, CIAO Prolog provides a mechanism that allows Prolog programs to invoke Java methods, offering a bidirectional communication and a reflection of Java objects into Prolog. This provides, for example, a natural way to execute Java-based engines (e.g., Jess) and communicate between the core framework and external Java packages. Furthermore, CIAO Prolog includes the PiLLoW library, a standardized Prolog library for Web programming, which provides the framework with capabilities for Web access (e.g., management of URLs) and parsing of HTML and XML documents to Prolog terms. Thus, we envision the core framework as the bridge between distinct execution models for heterogeneous knowledge bases.
- *Issue 2*:
  - *Issue 2(a)*: This issue will be addressed through the introduction of a module system, where different knowledge bases can be encoded (directly or indirectly) as distinct modules. The original import/export of CIAO Prolog can be combined with the languages for answer set modules of Baral et al. (2006) to allow forms of bidirectional communication between the core framework and the modules representing the knowledge bases.
  - *Issue 2(b)*: The core framework will provide the full computational power of Prolog, constraint logic programming, and answer set programming, combined through a sophisticated module and class system. Module interfaces will allow extraction of semantic information from the various knowledge bases (e.g., result of queries, models of knowledge bases) and reason with them.

- ◦ *Issue 2(c)*: The scoped inference is naturally supported by the module system of ASP-Prolog, for example, skeptical and credulous reasoning w.r.t. answer set modules.
- *Issue 3*: This aspect can be handled thanks to the combination, in ASP-Prolog and CIAO Prolog, of Web access capabilities along with the full computational power of Prolog.

We will now introduce the basic structure of our framework for modules and module interoperation.

Module Structure

As mentioned in the introduction to logic programming, we will assume that assert,retract,model,… are elements of $\prod_d$. Given a Ξ-program *P*, we say that *P* is pure if neither assert nor retract appear in the rules of *P*; otherwise we say that P is impure.

A module is composed of two parts: a module interface and a module body. A module interface has the form

← module: *t*
← import: $t_1,\ldots,t_k$
← export: $q_1/k_1,\ldots,q_m/k_m$
where

- *t* is a ground term, called the name of the module,
- t1,…,tk are ground terms, representing names of other modules, and
- q1,…,qm are predicates, and are k1,…,km non-negative integers, such that $ar(q_i)=k_i$.

The body of a module is a Ξ-program, for a given Ξ. In that case, we will say that the module is a Ξ-module. Given a module named *t*, we identify with the *export set of t* (denoted by *exp(t)*) the predicates $q_1,\ldots,q_m$ exported by *t*. We also identify with *imp*(*p*) the import set of *t*, that is, the names of the modules imported by *t*.

A program $P=\{M_{t1}, \ldots, M_{tk}\}$ is a collection of modules named $t_1,\ldots,t_k$. The *graph* of *P* (denoted by *graph*(*P*)) is a graph (N,E), where the set of nodes *N* is $\{t_1,\ldots,t_k\}$and

A program *P* is *admissible* if it satisfies the following properties:

- for each t_j we have that $imp(t_j) \subseteq \{t_1,\ldots,t_k\}$; and
- the graph *graph*(*P*) is acyclic.

The module structure can be expanded by allowing cyclic dependencies (i.e., two-way communications between modules) as well as OO-style organization of modules (e.g., as described by Baral et al. [2006]). We omit this discussion due to lack of space.

Example: Let us consider the modules associated to the bioinformatics services described earlier. One module, *gene_ontology*, is derived from the Gene Ontology. It will have an overall structure of the form:

← module: gene_ontology
← export: is_a/2, evidence_code/2, …
id(0016301)
is_a(0016301,0016772)
is_a(0004672,0016301)
is_a(0004674,0004672)
…
is_a(X,Y) ← is_a(X,Z), is_a(Z,Y)
…
evidence_code(0016772, rca)
…

A second module is obtained from the RuleML semantics of the functional annotation service:

← module: validated_annotation
← import: gene_ontology, …
← export: executable/1, causes/1, …
suspect(ProteinClass) ←
gene_ontology:evidence_
code(ProteinClass,rca)
classification(ProteinClass,
FuncAnnotation,go) ←
gene_ontology:is_a(ProteinClass,FuncAnno
tation),

not suspect(ProteinClass)

...

The resulting program P will be a set of modules { *planner, gene_ontology, validated_annotation*, ...}. □

General Semantics

In order to understand the framework, it is important to clearly define the semantics of the module-based system. We start by considering pure programs, and then we extend the discussion to impure programs.

Pure Programs

In this section, we propose a model-theoretic semantics for programs that do not contain any impure modules. Given a program, a *model naming* function τ is an onto function $\tau: H_P \rightarrow 2^{B}$P. We will use this function to assign *distinct* names to the models of the different modules. In the rest of this work, we will assume that the function τ is fixed.

Given a program $P = \{M_{t1}, \ldots, M_{tk}\}$, the acyclic nature of *graph*(P) guarantees the ability to construct a topological sort of $\{t_1,\ldots,t_k\}$, say $\eta_1,\ldots,\eta_k$, such that if (η_i,η_j) is an edge of the graph, then $i < j$.

Given the program P and a topological sorting of the modules $\eta_1,\ldots,\eta_k$, we construct the semantics module by module, following the topological sort order. The semantics of each module M_i will be given by a collection of models $\Phi^\tau(M_i)$, where $\Phi^\tau(M_i) \subseteq 2^{B}$P. Given a Ξ-program T, not containing any qualified atoms and not containing any occurrence of predicates from Π_d, we assume that its semantics NAT(T) is given. For example, if T is a Datalog with negation program meeting these conditions, then NAT(T) will be the set of answer sets of T, while if T is a pure Prolog program (i.e., definite logic program without extra-logical predicates such as assert and retract), then NAT(T) contains the least Herbrand model of T.

This suggests a natural way to handle the semantics Φ^τ of a program P. Φ^τ is a mapping of the form $\Phi^\tau: P \rightarrow 2^{B}$P. Once the topological sort $\eta_1,\ldots,\eta_k$ of the modules is given, we can construct Φ^τ as follows:

- the semantics of $M_{\eta 1}$ is given, since it does not import any other modules, and

$\Phi^\tau(M_{\eta 1}) = \mathrm{NAT}(M_{\eta 1})$

- the semantics of $M_{\eta i}$ can be constructed by computing the natural semantics of a "reduct" of the module,

$\Phi^\tau(M_{\eta i}) = \mathrm{NAT}(MR(M_{\eta i}, \Phi^\tau))$

as defined next.

Let us consider a module $M_{\eta i}$ of P. Then:

- If t: A is a ground qualified atom and $t \in$ *imp*$(M_{\eta i})$, then

$M_{\eta i} \models_\Phi \tau$ t: A iff for each model M $\in \Phi^\tau(M_t)$ we have that M $\models$ A.

- If t: A is a ground qualified atom and $t \notin$ *imp*$(M_{\eta i})$, then $M_{\eta i} \models_\Phi \tau$ t: A if there exists $x \in$ *imp*$(M_{\eta i})$, M $\in \Phi^\tau(M_x)$ such that π(A) ∈ exp(x), τ(t)=M and M $\models$ A.
- $M_{\eta i} \models_\Phi \tau$ t: model(s) if t ∈ *imp* $(M_{\eta i})$ and τ(s) ∈ $\Phi^\tau(M_t)$.
- If *not t: A* is a ground qualified literal and $t \in$ *imp*$(M_{\eta i})$, then

$M_{\eta i} \models_\Phi \tau$ not t: A if $M_{\eta i} \not\models_\Phi \tau$ t: A.

The *model reduct* of M_i w.r.t. Φ^τ, denoted $MR(M_i, \Phi^\tau)$, is defined as follows:

- Remove from M_i all rules that contain in the body a qualified element l such that $M_i \not\models_\Phi \tau l$.
- Remove from the remaining rules all occurrences of qualified elements.

One can easily see that $MR(M_i, \Phi^\tau)$ is a program without qualified atoms whose semantics is defined by NAT. This allows us to set

$\Phi^\tau(M_{\eta i}) = \mathrm{NAT}(MR(M_{\eta i}, \Phi^\tau))$

From now on, we will denote with $\Phi^{\tau/P}$ the semantics of a program P.

Example: Let us continue the example we started earlier. The module *gene_ontology* is a Datalog program. Thus, NAT(*gene_ontology*) = { M_0 } where M_0 is its least Herbrand model; some of the elements in M_0 are:

is_a(0016301,0016772), is_a(0004672,0016301),

is_a(0004674,0004672), is_a(0004672,0016772),

is_a(0004674,0016772), is_a(0004674,0016301),...

The module *validated_annotation* is a Datalog with negation program, and its reduct will be performed with respect to the semantics of *gene_ontology* (and the other imported modules). For example, the rule

classification(ProteinClass, FuncAnnotation, go) ←

gene_ontology:is_a(ProteinClass, FuncAnnotation),

not suspect(ProteinClass)

will be grounded and only the instances for which the is_a atom is true in M_0 will be kept, for example,

classification(0004674, 0016772, go) ← not suspect(0004674)

Only the answer sets of the resulting program will be maintained as NAT(*validated_annotation*). □

Impure Programs

We say that a program is impure if it contains impure modules and/or it contains modules that are not based on logic programming. The use of impure programs allows the planner to provide the Web services with knowledge about the state of the world the services will be executed in. It also allows the reasoner to temporarily modify the content of a module (e.g., a module describing an action) to support the planning process. This is particularly important when dealing with very complex plans (Son & Pontelli, 2007) or incomplete knowledge (Tu et al., 2006).

Let $P=\{M_{t1}, \ldots, M_{tk}\}$ be a program; for the sake of simplicity, we assume that $t_1,\ldots,t_k$ is a topological sort of *graph*(P). We also consider impure programs under the following restrictions:

- The planner is itself a module, encoded using Prolog (pure or impure), and it is represented by the module M_{tk}.
- The impure predicates assert and retract are allowed to appear only in Prolog modules.

Because of the nonlogical nature of the impure predicates, we rely on an operational semantics to chaacterize the meaning of programs.

The *state* of a computation is given by a tuple $\langle G,\theta, P\rangle$, where G is a Prolog goal, θ is a substitution, and P is a program. The operational semantics for a goal executed in the module named t_i is defined through a state transition system $\langle G, \theta, P\rangle \rightarrow_i \langle G', \theta', P'\rangle$ where

- If $G = (A \wedge Rest)$ and $\pi(A) \in def(M_{ti})$, and $h \leftarrow body$ is a variant of a rule in M_{ti} such that σ is the most general unifier of $A\theta$ and h, then we have that $G'=body\wedge Rest$, $\theta'=\theta\sigma$,[3] and $P'=P$.
- If $G = (t{:}\ A \wedge Rest)$, $t_j \in imp(M_{ti})$, $\pi(A) \in def(M_{tj})$, t_j is a Prolog module, and $\langle A, \theta, P\rangle \rightarrow_j \langle \square, \theta', P'\rangle$ then we have $G'=Rest$
- If $G = (t{:}\ A \wedge Rest)$, $t_j \in imp(M_{ti})$, $\pi(A) \in def(M_{tj})$, t_j is an ASP/datalog module, and let σ be a ground substitution fpor $A\theta$ such that $A\theta\sigma$ is true in each model in $\Phi^{\tau/P}(M_{tj})$ then we have that $G'=Rest$, $\theta'=\theta\sigma$, and $P'=P$.
- If $G = t{:}\ model(t') \wedge Rest$ and $t \in imp(M_{ti})$, and σ is a ground substitution such that $t'\theta$ is ground and $\tau(t'\theta) \in \Phi^{\tau/P}(M_t)$, then $G'=Rest$, $\theta'=\theta\sigma$, and $P'=P$.
- If $G = t{:}\ A \wedge Rest$ and there exists $t' \in imp(M_{ti})$, and σ is a substitution such that $(t{:}\ A)\theta\sigma$ is ground, $\tau(t\sigma) \in \Phi^{\tau/P}(M_{t'})$, and $A\theta\sigma$ is true in $\tau(t\sigma)$, then we have that $G'=Rest$, $\theta'=\theta\sigma$, and $P'=P$.

- If $G = t$: *assert*(*Head*, *Body*) $\wedge$ *Rest* and σ is a substitution such that $t\sigma \in imp(M_{ti})$, then we have that $G' = Rest$, $\theta' = \theta\sigma$, and $P' = (P \setminus \{M_{t\sigma}\}) \cup N_{t\sigma}$ where $N_{t\sigma} = M_{t\sigma} \cup \{ (Head \leftarrow Body)\, \sigma \}$.
- If $G = t$: *retract*(*Head*, *Body*) $\wedge$ *Rest* and σ is a ground substitution such that $t\sigma \in imp(M_{ti})$ and $(Head \leftarrow Body)\sigma \in M_{t\sigma}$, then we have that $G' = Rest$, $\theta' = \theta\sigma$, and $P' = (P \setminus \{M_{t\sigma}\}) \cup N_{t\sigma}$ where $N_{t\sigma} = M_{t\sigma} \setminus \{(Head \leftarrow Body)\sigma\}$.

Given a goal *G* and a program *P* with main module M_{tk}, we say that θ is a solution of *G* if

where $\rightarrow^*$ denotes an arbitrarily long sequence of transitions.

Example: Let us continue with our example. The ability to perform service composition using logic-based planning provides the added advantage that the plan and the complete trajectory are represented by logic statements, and it is possible to write additional modules to reason about the trajectory. For example:

- Given a list of proteins L we can write a simple query that will provide the functional class to which the majority of the proteins belong to:

```
majority(L, Class) ←
findall(C,(member(X,L),annotate(X,C)),Funs),
findall(K-F, (member(A,Funs),
findall(A,member(A,Funs),S),
length(S,K)
),
Res),
keysort(Res,Result),
last(Result,Class)
annotate(P,F) ←
assert(planner:initially(have_protein(P))),
planner:holds(go_classification(P,F),length)
```

- Let us assume that the service description includes an estimate of the reliability of the service, provided by the service provider and measuring the ability of the service to quickly respond to a request. This is translated in a fact of the form low_load or high_load. The logic programming module allows the action to successfully return only in case of low load, that is, the definition of the action in the service description module will include

```
executable(…):- low_load.
```

If the resulting plan is sufficiently long, we would like to replace the load information with a pessimistic value, which may reflect the fact that the load figure is not reliable any longer. We could modify the rule used by the planner:

```
holds(F,T+1) ← action(A), occ(A,T),
(T > Threshold -> retract(A:low_load); true),
A:causes(F), A:executable(List), holds(List,T)
```

□

FRAMEWORK IMPLEMENTATION

Logical Core Implementation

The implementation of the logical core is based on the combination of two logic programming systems: *CIAO Prolog* (Bueno et al., 1997) and *Smodels* (Niemelä & Simons, 1997). *CIAO Prolog* is a full-fledged Prolog system, with a sophisticated module system, and designed to handle a variety of flavors of logic programming, including constraint logic programming (over reals and finite domains), fuzzy logic programming, and concurrent logic programming. *Smodels* is a logic programming engine which supports computation of the well-founded and answer set semantics for NAF-datalog programs. The proposed system is composed of two parts: a *preprocessor* and the actual CIAO Prolog system.

The input to the preprocessor is composed of

- The main planner module (*Pr*), typically a Prolog module, which extracts information from a planner encoded in ASP;

- A collection of CIAO Prolog modules ($m_1,\ldots, m_n$);
- A collection of ASP modules ($e_1,\ldots, e_m$).

The main task of the preprocessor is to transform the ASP modules to enable their use in the CIAO Prolog system and to manage the interaction with the *Smodels* solver.

The transformation of each ASP module leads to the creation of two entities that will be employed during the actual program execution, that is, an *interface module* and a *model class*. These are described in the following subsections. The preprocessor will also automatically invoke the CIAO Prolog top-level and load all the appropriate modules for execution. The interaction with the user is the same as the standard CIAO Prolog top-level.

Interface Modules

The preprocessor generates one interface module for each ASP module present in the original input program. The interface module is implemented as a standard CIAO Prolog module and it provides the client Prolog modules with the predicates used to access and manage the ASP module. The interface module is created for each ASP module by instantiating a generic module skeleton

The overall structure of the interface module is illustrated in Figure 5. The module has an export list which includes all the predicates used to manipulate ASP modules (e.g., assert, retract, model) as well as all the predicates that are defined within the ASP module.

Each module has an initialization part, which is in charge of setting up the internal data structures and invoke the ASP solver (*Smodels*) for the first time on the ASP module. The result of the computation of the models will be encoded as a collection of *model objects* (see the description of the model classes in the next subsection). The module will maintain a number of internal data structures, including a representation of the ASP code, a representation of the parameters to be used for the computation of the answer sets (e.g., values of constants), a list containing the objects representing the models of the ASP module, a counter of the number of answer sets currently present, and so forth.

The preprocessor creates a graph-module structure which represents the call hierarchy of modules. If a Prolog/ASP module u_p calling another prolog/ASP module u_c then u_p is called the parent module and u_c is one of its children. The tree-module structure is stored in each interface module.

Each interface provides also a timestamp predicate, which is used to inform of the time at which the module's semantics have been last computed (recorded as a discrete system time); each interface module will recompute the local semantics whenever the timestamp of one of the imported modules changes. This allows the system to propagate the effect of changes (e.g., assert/retract) to all modules that depend on the modified one.

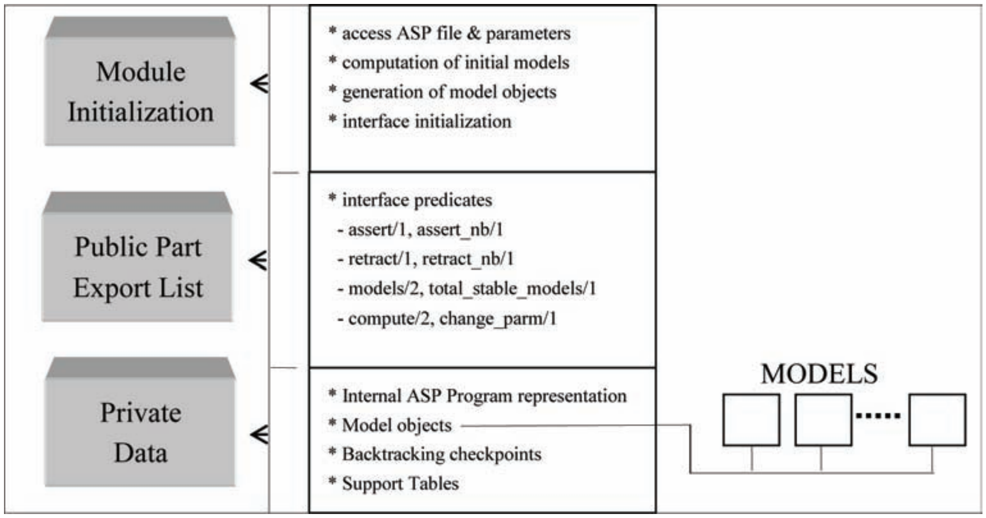
Finally, the preprocessing will add code to handle the different types of goal qualification.

Model Classes

The preprocessor generates a CIAO class definition for each module. The objects obtained from the instantiation of such class will be used to represent the individual models of the module. In particular, for an ASP module we will have one instance for each answer set, while for a Prolog module we will have a single instance, corresponding to the least Herbrand model.

Prolog and ASP modules can obtain reference to these objects (e.g., using the model predicate supplied by the interface module) and use them to directly query the content of one model. The definition of the class is obtained through a straightforward parsing of the export declaration of each module, to collect the names of the predicates defined in it; the class will provide a public method

Figure 5. Structure of an interface module



for each of the predicates present in the module's export list. The class also defines a public method add/1 which is used by the interface module to initialize the content of the model.

To facilitate computation, the preprocessor generates an additional module for each ASP module, called skeptical module. The module is instantiated to a collection of facts representing the elements that have the same truth value in all answer sets of the corresponding ASP module.

Further Implementation Details

Further details about the implementation of this framework can be found by Pontelli, Son, and Baral (2006). Let us discuss only some significant aspects here.

ASP-State: Every ASP-module has a set of models, atoms, and skeptical model called ASP-states. A stack is used to store the ASP-states which will be used for backtracking. Any change in the ASP-state of an ASP module m, requires that all the ASP ancestor modules of m change their own ASP-states. This can be done with the help of the tree-module structure.

Partial Grounder: In order for the Smodels system to ground the ASP-modules, all qualification of the form (α: *t*) have to be computed and stored as new facts with a newly created ASP-variable. Therefore, if we have a positive qualification literal (α: *t*), then the partial grounder will evaluate the predicate *t* in module α. If α is a Prolog module, then the built-in predicate findall is used to compute all possible answers to the goal ?-t. If α is an ASP-module, then the predicate *t* is evaluated against the skeptical answers of the ASP-module α. If α is an ASP-model name, then predicate *t* is computed against the corresponding answer set named α. After that, all ground values of *t* are added as facts into the ASP-module.

The same rewriting rules are needed for negative qualification literals (*not* α: *t*), domain qualification literals, cardinality qualification literals, and weight qualification literals.

RuleML Specific Issues: RuleML knowledge bases are retrieved and encoded as modules to support the reasoning activities. The translation process relies on the PiLLoW library (which supports HTTP protocol and basic XML manipulation) and the sophisticated XML library provided by CIAO Prolog (which allows XML parsing, URIs management, and even XPath queries). The translation process is performed in two steps. During the first step, the RuleML document is parsed and converted into a Prolog XML representation (as a compound Prolog term). In the second phase, the Prolog XML representation is parsed and translated into logical rules and collected into a module.

The import component of the module is automatically derived by retrieving those atoms used in the program and linking (through URIs) to external components (e.g., used in the rel elements). By default, the export list will contain all the rel that appear as heads of rules/facts in the knowledge base.

Another specific issue related to RuleML is the inclusion of ECA rules. They can be effectively included in the proposed framework, as discussed by Pontelli, Son, and Baral (2006).

RELATED WORK

The importance of developing languages and frameworks to integrate different aspects of semantic Web reasoning has been highlighted in the literature. Most of the existing focus has been on integrating rule-based reasoning with ontology reasoning. Two relevant contributions in this field are represented by the work of Golbreich (2004) and Laera, Tamma, Bench-Capon, and Semeraro (2004). Golbreich (2004) describes a combination of reasoning about ontologies (encoded in OWL) with rule-based reasoning (with rules encoded in SWRL and processed by the Jess system). Different from our framework, the system is not based on logic programming (relying on Java's Jess platform) and limited to SWRL's rule format.

A wider-breadth approach, and closer to the spirit of ASP-Prolog, is SweetProlog (Laera, Tamma, Bench-Capon, & Semeraro, 2004). SweetProlog offers a platform for integrating rules and OWL ontologies build using logic programming. Rules are encoded using OWLRuleML, which represents an OWL ontology for the RuleML dialect captured by the courteous logic programming scheme (Grosof, 1999). Both rules and OWL ontologies are mapped to Prolog (specifically, the Java-Internet Prolog engine) for interrogation and reasoning. This project has a greater emphasis on integration between a fixed-rule language (the fragment of RuleML captured by OWLRuleML) and OWL ontologies, providing an orthogonal contribution to the integration problem.

A remarkable direction has been explored in the context of the DLV project; dlvhex (Eiter, Ianni, Schindlauer, & Tompits, 2006) is an extension of DLV:

- It allows answer set programs to invoke external source of computation, that is, truth value of selected predicates can be achieved through external deduction systems, for example, accessing RDF statements; and
- It allows answer set programs to contain higher-order atoms.

This language has been motivated by similar reasons as those in this chapter, to support semantic Web reasoning (Eiter et al., 2006; Eiter, Lukasiewicz, Schindlauer, & Tompits, 2004), with particular emphasis on integration of ontologies.

Relatively few proposals have appeared in the literature dealing with the high-level integration of different forms of logic programming reasoning, specifically top-down goal-oriented Prolog and bottom-up answer set semantics. ASP-Prolog (Elkhatib et al., 2006), on which the work described in this chapter builds, is a system that provides Prolog programs with the ability to seamlessly access modules processed under answer set semantics. A simplified interface, between the *Smodels* system and XSB Prolog, has been described by Castro, Swift, and Warren (2002).

Lower level interfaces between answer set systems (DLV and *Smodels*) and traditional imperative languages have been developed (Calimeri & Ianni, 2005; Ricca, 2003; Syrjanen, 1998).

CONCLUSION AND FUTURE WORK

In this chapter, we addressed the issue of dealing with heterogeneous Web services in the context of the Web service composition problem. We presented a logic programming framework for intelligent Web service composition and a preliminary prototype of parts of the framework within the ASP-Prolog system. The key idea in our framework is to view Web services as actions and Web service composition as a planning problem. Under this view, Web service documents (e.g., WSDL or RuleML documents) are encoded as logic programs which can be reasoned about and combined using logic programming techniques. The variety of semantics of logic programs supports a natural way to deal with heterogeneous Web service description and ontologies. Furthermore, the use of answer set planning in Web service composition allows us to easily incorporate users' preferences and effectively handle incomplete knowledge.

As future work, we propose to demonstrate the framework on real-world applications, with particular focus on applications on description and manipulation of bioinformatics Web services. The proposed framework is also expected to have a significant role in facilitating the deployment of and reasoning about rule-bases constructed according to the guidelines of the rule interchange format (RIF) initiative (Ginsberg, Hirtle, McCabe, & Patranjan, 2006). Recent developments in RIF have highlighted the importance of being able to merge rule sets, and the requirement of supporting standard ways to characterize rule sets dialects. The proposed framework could easily avail of such standardized identification of dialects to guide the automated translation of RIF rule sets to ASP-Prolog modules.

Chapter 2.7
The Effectiveness of Scaffolding in a Web-Based, Adaptive Learning System

ABSTRACT

This study combined ideas from learning hierarchy and scaffolding theory to design a web-based, adaptive learning system to investigate the effectiveness of scaffolding for elementary school students having different levels of learning achievement. The topic chosen for learning was the Three States of Water. A quasi-experiment was conducted. In this experiment, students were divided into three groups: control group (without scaffolds), experimental group A (scaffolds providing by on-line conversation) and experimental group B (scaffolds providing by face-to-face conversation). The experimental results showed significant improvement for students after they had studied using the web-based, adaptive learning system. Specifically, scaffolds in the form of face-to-face conversations greatly enhanced the learning of high-achievement students. However, there were no significant differences between the low-achievement students with or without the provision of scaffolds. It was also discovered that the web-based, adaptive learning system could help students develop their learning responsibility.

INTRODUCTION

The purpose of science education is to provide students with scientific knowledge, concepts, attitudes and methods for application in their daily lives. The role of a teacher is to assist students in learning and solving problems. At the beginning, students are usually interested in learning science, but to some extent, they lose it or become confused, especially when learning abstract concepts. The Three States of Water is a learning unit containing abstract and complicated concepts for elementary students.

Use of the Internet and instructional technology can help teachers and students in many ways. It is easier for students to understand abstract concepts if their learning process is assisted by instructional technology. This study combined with ideas of learning hierarchy and scaffolding theory to the design of a web-based, adaptive learning system to improve the quality of web-based learning.

The major purpose of this study was to investigate students' learning via a web-based, adaptive learning system where scaffolds were provided to help the students to study the concept of the Three States of Water. This study also tried to find out whether students' learning responsibility was being developed during their learning process.

The concept of *scaffolding* is based on Vygotsky's social constructivist view of learning (1978). Vygotsky proposed that there were two major factors, i.e., culture and social context, which influence learning. He claimed that every mental function in a child's development first came from the social interaction with an adult. This kind of interaction provides a supportive environment in which children can extend their current knowledge and skills. The supported situation occurs in what Vygotsky referred to as the *zone of proximal development*. That is the area between what children can do independently and what they can do with assistance, such as they get from teachers and other students. The assistance that other people provide is a *scaffold* for a child. Given repeated experiences, children can internalize the supported situation of the mental processes, and can engage in them in new contexts (Clark & Graves, 2005).

Two sources of knowledge are suggested by Vygotsky. The first is *everyday knowledge*, i.e., gut knowledge, instinctive knowledge and spontaneous knowledge. This type of knowledge is influenced by peer interaction, language and experience of the individual who tries to understand his or her environment. The second is from formal education in the classroom, which is called *formal knowledge* and it possesses strict logic and clear definitions. Therefore, learners construct meaningful knowledge through both their daily lives and school experiences.

However, some scientific concepts are very abstract and difficult for students to grasp. In addition, they may often be influenced by different cultural and social environments. For example, the concept of "The sun rises in the east and falls in the west" generally exists in textbooks and daily communication, and students have this *misconception* before they are educated with *formal* knowledge. Students may think the experiences they have in daily life constitute their full knowledge base. Therefore, it is important for them to know if the knowledge they have received is formally right or not.

According to scaffolding theory, teachers should hold continuous and active conversations with students to find out the possible levels of their potential development (where they are) and to control their learning environments (where they should be) by providing proper support to make the concepts they acquire consistent with scientists' current definitions.

Empirical Studies on Related Topics

Osbome and Cosgrove (1983) discovered in their study that students lacked the support of substantial scientific concepts when they explained changes in the states of water. The finding was that they had only superficial knowledge of the terms and expressions. For example, some students would think that a solid changing into a liquid will lose weight or condensation will make particles more compacted. Bar and Travis (1991) investigated the concepts of liquid and gas as possessed by Israeli children and they found that most children had misconceptions about evaporation and condensation, suggesting that it was more difficult for the children to understand these abstract concepts.

The curriculum for science and technology in elementary schools in Taiwan includes the learning about substances and energy, natural environments, ecological conservation and information technology. The learning unit chosen in this study was focused on the important concepts of the Three States of Water and changes such as solidification, melting, condensation and evaporation, because it is related directly or indirectly to most of the subjects mentioned above. Although most of the phenomena can widely be seen in our daily lives, students may still have misconceptions due to their own mis-understanding and mis-reasoning.

After reviewing related research conducted in this area, the authors found that most children do have misconceptions about the states of water. Only a few of them think that vapor can also become water at a low temperature. Very few of them discover that wind blowing can make water evaporate more easily. Senior students in elementary schools know much about evaporation, but they know little about condensation as a formal scientific concept. Many children think condensation is solidification.

In general, condensation is a more difficult concept than evaporation for students to understand. Most students do not know the white smoke above boiling water is a gas or vapor; they think of it as smoke. Again, some students believe the weight of water changes after it becomes ice. This study therefore designed diagnostic tools and adaptive learning mechanisms to correct the students' misconceptions that often occur.

Current Status of Adaptive Learning

Electronic Learning (or e-Learning), sometimes provided as online learning or web-based learning, means learning through digital content to reach the goal of learning anytime and anywhere. In general, e-Learning includes any means of delivering teaching materials through networks (Whittington, 2000). Since 1990, the Internet has developed rapidly. After the establishment of the World Wide Web (WWW), many educational websites emerged (Berge & Collins, 1995; Cahoon, 1998; Collis, 1996; Porter, 1997).

Digital content may consist of multimedia as well as online interactions, allowing learners to play a more active role in the process of learning (Aivazidis, Lazaridou & Hellden, 2006). Learners' locations are no longer limited to classrooms, and they can learn anytime they want. In addition to a variety of teaching materials, e-Learning has gradually become the most convenient way for students to access new information and knowledge.

Since traditional ways of learning can not meeting the needs of individual learners, an increasing number of researches in adaptive learning systems have been conducted in recent years. An adaptive learning system can provide suitable contents for different learners according to their backgrounds, prior knowledge, individual demands and learning statuses (Papanikolaou *et al.* 2002).

Atkinson (1976) suggested that an efficient instructional strategy must be adaptive. Therefore, an adaptive learning system must change instructional strategy according to learners' situations during a learning process under teacher's control to enhance learning and achieve the expected instructional objectives. Besides, the system can collect some features of learners and store them in certain learning modules, which can be used to provide suitable contents for different learners (Brusilovsky,1996).

Web-based learning has become more and more popular today. A web-based learning system is accessible by a large number of students at the same time according to individual necessity and learning pace, and it is not limited by time or space. Therefore, it is suitable for the development of adaptive learning environments (Chang, 2005). According to Lin's study (1998), an adaptive learning system can achieve the goal of teaching students according to their aptitudes in a normal class grouping environment, and it makes learning more active and efficient.

A personalized web-based learning system was proposed by Chang *et al.* (2006) based on item response theory (IRT). The system was aimed at providing a suitable learning environment by considering the learning portfolios of content difficulty, learner's ability and conceptual coherence. Lin and Kuo (2005) developed a virtual learning environment based on the theory of learning objects and constructivism. The learning contents and statuses of learners on the system can be individualized to achieve the goal of adaptive learning. Also, learners can cooperate in the inhabited virtual world to increase learning effectiveness during their learning processes.

Because e-Learning systems are usually developed in accordance with *learners*' requirement in terms of platforms, materials, presentation styles and virtual communities, it often occurs that some systems are only suitable for certain users. If a system is transferred to another environment, for some other people, tremendous manpower and costs must be spent in making changes (Dodds, 2001a; 2001b). To solve this problem, international standard organizations have specified e-Learning standards. E-Learning systems such as SCORM, AICC, IEEE, IMS, IEEELOM, ARIADNE, and Microsoft promulgate these standards (Hodgins & Conner, 2000). Among them, SCORM has now become an important standard for e-Learning content (Chang, Hsu, Smith & Wang, 2004).

Learning contents that conform to SCORM standards have reusable and sharable features. However, there are still some disadvantages, such as complicated definitions for the rules of learning activity and huge frameworks for learning contents, making it difficult to manage, reuse and combine these with traditional educational theories. E-Learning does need a good system to support online services, such as course design, learning resource delivery, integration of courses and teaching methods (Suthers, Johnson & Tillinghast, 2002), etc. For this reason, the Graduate School of Online Learning Applications, National Chiao Tung University, Hsinchu, Taiwan developed their Object Oriented Learning Activity System (OOLAS) based on the standards of SCORM, Learning Design Specification, Knowledge Tree and Multibook. In the SCORM standards, most metadata models were used to define learning materials (Su, Tseng, Lin & Lu, 2005). Chang *et al.* proposed in their study (2004) a metadata model to define online assessment. OOLAS is composed of an authoring system and a learning system. In addition to a simple process for editing materials, it presents the contents of curricula easily and allows teachers to plan related programs to assist students with learning effectively. OOLAS also allows teachers to design the related tests of concepts.

In this study, the authors used OOLAS to develop a web-based, adaptive learning system that was integrated with scaffolding to improve the learning efficiency of students. They also developed teaching materials for the concepts of the Three States of Water. The system modules were: diagnostic tools, a test-item database, adaptive learning modules and learning contents for the scientific concepts in the Three States of Water (Figure 1).

The diagnostic tools were designed using two-tiered test items to identify the prior misconceptions of students. After detecting their misconceptions, an adaptive learning module was initiated by a rule-based inference engine to generate individualized learning content for students according to the particular misconceptions of the particular student.

RESEARCH DESIGN

This study was conducted using a quasi-experimental design. A total of 200 students belonging to two elementary schools in Taipei County were chosen for the experiment. The authors divided the students into a control group and experimental groups to investigate the learning of students with or without scaffolds. The authors also measured the changes in their learning responsibility after the e-Learning. For the control group, the students studied using the web-based, adaptive learning system by themselves without the provision of any scaffolds. For the experimental groups, the students could ask teachers for help if they had questions during the learning processes and after the diagnostic tests. There were two experimental groups, provided with scaffolds in different ways. For experimental group A, the scaffolds were provided in the form of online conversation between the teachers and students. For experimental group B, the scaffolds were provided in the form of face-to-face conversations between the teachers and students. For both media of communication, teachers provided scaffolds by discussing with the students to find out their problems and correct their misconceptions.

Research Procedure

This study selected the Three States of Water as the topic of learning. Therefore, the authors first analyzed the related concepts covered by textbooks of elementary schools, and then developed a learning hierarchy according to these concepts. Based on the learning hierarchy, the authors used the diagnostic tools of the web-based, adaptive learning system to find out the misconceptions of students. The authors developed the adaptive learning modules by using a rule-based inference engine to provide remedial instructions for students according to a categorization of the types of their misconceptions. After that, the authors conducted a quasi-experiment to find out the influence of scaffolding on students when they were learning using the system.

Research Samples

The samples in this study were 5th and 6th grade students, randomly selected from two elementary schools in Taipei County. Because these students had already taken computer courses during their 3rd grade year, by the time of this experiment, they had two to three years of experience in using computers and the Internet. This reduced the influence of computer skills on the effectiveness of e-Learning. As stated, the students were divided into the control group (without scaffolds) and the experimental groups (with scaffolds). The experimental groups consisted of group A (providing scaffolds via online conversation) and group B (providing scaffolds via face-to-face conversation).

According to a pretest, students with scores above the first 50% were classified as high achievement students while the remaining 50% were classified as low achievement students. In the control group, there were 33 high-achievement students and 33 low-achievement students, making

Figure 1. The operation of the web-based, adaptive learning system

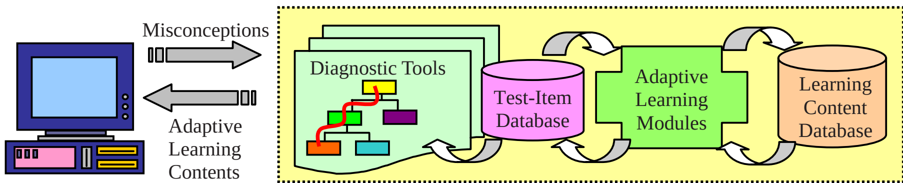

Table 1. The number of students in each group

Content	Groups	Scaffolds	Achievement	Number of Students
Three States of Water	Control Group	None	High	33
			Low	33
	Experimental Group A	Online Conversation	High	33
			Low	32
	Experimental Group B	Face-to-Face Conversation	High	35
			Low	34
Total Number of Students				200

a total of 66 students. In the experimental group A, there were 33 high-achievement students and 32 low-achievement students, making a total of 65 students. In the experimental group B, there were 35 high-achievement students and 34 low-achievement students, making a total of 69 students (as listed in Table 1).

Diagnostic Tools

The questions to diagnose misconceptions about the Three States of Water in this study were modified from the paper-based test questions designed by Chang (2003), who analyzed the misconceptions that students in elementary schools often have. Since two-tier test items have been used widely and efficiently in discovering misconceptions and conceptual changes (Tsai & Chou, 2002), the authors thus used them to develop the diagnostic tools based on the empirical study of Lin (1995). The authors consulted three science teachers and two experts in science education about the validity of the test items and diagnostic tools. Finally, the two-tier test items were uploaded and stored in the test-item bank by using authoring tools of the system. An example of the two-tiered question follows:

There are two identical wet towels. One is spread and the other is folded. Which one do you think will dry first?

Answer: ____(A) Folded one. (B) Both at the same time. (C) Spread one. (D) I don't know. Explain your reason:.

Pretest and Posttest

Limited by the sampling method and number of samples, we adopted a non-equivalent group pretest-posttest design in our experiment, and adjusted the difference in students' background using an analysis of covariance (ANCOVA) to investigate the influence of scaffolding on the students with different levels of achievement. The questions in the pretest and posttest were designed based on the learning contents and related concepts of the Three States of Water. The reliability of the achievement test was verified by an internal-consistency reliability test with Cronbach α=0.71.

After removing the inappropriate questions, there were 113 multiple-choice questions left. Among them, 37 questions were selected to form the pretest and posttest, and the remaining questions were used as diagnostic test items. The scores of the pretest were used to measure the students' levels of achievement. The questions in the posttest were similar to that of the pretest, enabling the authors to compare the experimental and control group results. An example of a question follows:

Which of the following is the correct description for the speed of evaporation? (A) The more humid the environment is, the faster the evaporation is. (B) The hotter the environment is, the faster the evaporation is. (C) The more airtight the environment is, the faster the evaporation is.

Measurement of Learning Responsibility

In this study, the authors used a questionnaire to measure the development of self-learning responsibility after the web-based learning. The questionnaire was developed by the researchers and verified by three elementary school teachers and two experts in the research area of science education. It contained 18 questions. Each question had five scales in its answer: 5 points for very likely, 4 points for likely, 3 points for no opinion, 2 points for not likely, and 1 point for not likely at all (as shown in Appendix I). This is an indicator for the degree of development of the students' learning responsibility. All questions in this measurement were positive-response designed. Thus, the more points a student gained, the more responsible and active he or she was in learning. The reliability of this measurement was verified by testing on 32 6th grade students and the total internal consistency was calculated as Cronbach α=0.89.

INSTRUCTIONAL DESIGN

The principle of instructional design in this study was based on Gagne's learning hierarchy (1985). The major concepts of the Three States of Water were analyzed to form a hierarchical diagram. The learning hierarchy was constructed according to competence indicators for the curriculum of science and technology in elementary schools in Taiwan. For example, the concepts of the Three States of Water are based on solidification, melting, evaporation and condensation. Deeper, the concept of solidification contains the lower-level concepts of water changing from liquid to solid, increasing volume, and mass conservation. Because condensation, solidification, melting and evaporation are the major concepts for the Three

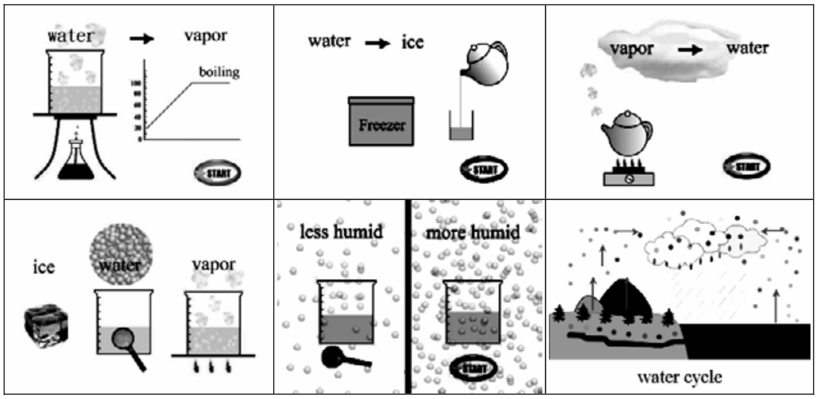
Heating speeds up evaporation. 36. Heating causes water to evaporate.

Figure 3. The online experiments incorporated in the learning content



States of Water in elementary science courses, a number of teaching activities were designed to introduce these concepts.

The authors encoded all concepts in the learning hierarchy by number to simplify the diagnostic sequences. A student with a misconception at a high level implies that he or she may have misconceptions at lower levels and thus requires further diagnostic processes. Generally, the higher the hierarchical level is, the smaller the number is. For example, the highest-level concept is “three states of water”, which was encoded as 1. The second-level concepts are “solidification”, “melting”, “evaporation”, “condensation”, and which were encoded as 2, 3, 4, and 5. The concept of “solidification” (2) contains the lower-level concepts of water changing from “liquid to solid” (6), “mass conservation” (7), and “increasing volume” (8) as shown in Figure 2.

Because experiments and observation are very important for the establishment of scientific concepts, the authors designed several online experiments to simulate the phenomena of the Three States of Water to help students develop their scientific concepts (Figure 3). The experiments were designed using Flash to provide an interactive user interface, animations for the simulation of the phenomena and concepts in the Three States of Water.

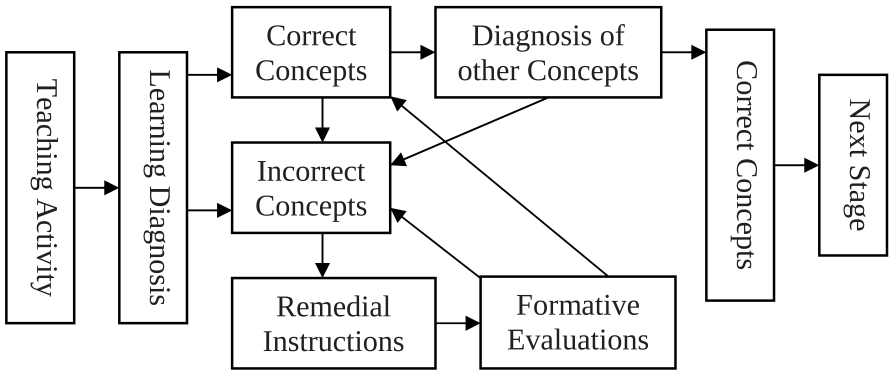
In this study, there were four lessons for all students to complete. After each one, the students did a diagnostic test to see if they had completely understood the scientific concepts. The design of diagnostic tests followed the sequence of solidification, melting, evaporation and condensation. After students had completed a learning activity, they were directed to the diagnostic tests to see if their understanding about the related concepts was correct. If the concepts of students were valid according to the diagnostic results, they could keep on learning the remaining concepts. Otherwise, the students had to proceed with remedial instruction to correct their misconceptions.

For example, if students passed the tests on the concept of solidification, they could move to the next stage to start the learning activities on the concept of condensation. Otherwise, they were directed to the remedial instructions for the correction of previous misconceptions, followed by formative evaluations to guarantee the conceptual changes had been internalized. When all misconceptions were corrected after remedial learning activities, they could start learning the contents for the next stage (Figure 4).

RESULTS AND DISCUSSIONS

The major purpose of this experiment was to investigate students’ learning enhancement on the web-based, adaptive learning system and the

Figure 4. Learning diagnosis design of the system



development of learning responsibility after the e-Learning. In addition, the learning statuses of students, such as misconceptions and conceptual changes, were also studied by analyzing learning records. Students' scores in the pretest and posttest were analyzed using statistical software SPSS to calculate the mean and standard deviation for each group.

Learning Effectiveness

Based on the analysis of the T-test, all students performed very well on the web-based, adaptive learning system, no matter whether they were high-achievement (t=7.27, p<0.01) or low-achievement (t=13.63, p<0.01) students. This revealed that the system was efficient for students in learning the concepts in the Three States of Water.

Based on the analysis of distribution in students' misconceptions, over 70% of the students had valid concepts about melting before learning activities. However, there were also 65% of the students with misconceptions about condensation so that they spent more time in the related remedial instruction. According to the results of the T-test, we found the students made significant progress in the areas of solidification (t=2.37, p<0.05), evaporation (t=2.98, p<0.05), and condensation (t=2.57, p<0.05). Besides, the results showed that more students understood the concept of evaporation than that of condensation, which agreed with the results of the studies by Lin (1995), Lai (1994) and Chang (1997).

Because the teaching materials were designed based on Gagne's notion of learning hierarchy (1985), it was effective for learning the concepts in the Three States of Water. Also, the web-based, adaptive learning system was useful for teachers in reducing the workload, while increasing the learning effectiveness of the students. According to the diagnostic results, students could go immediately through remedial instructions to correct their misconceptions. It could also solve the problem of insufficient teachers to provide feedback for individual students. Besides, through the records of learning processes, it was easy to know the status of each student and provide appropriate support.

High-Achievement Students

The effective samples of the high-achievement students contained 29 students in the control group, 31 students in the experimental group A, and 32 students in the experimental group B. Using ANCOVA, the homogeneity of the regression slope was tested (f=0.32, p>0.05), indicating that the homogeneity assumption was met. After the ANCOVA analysis, the results showed that there were significant differences among these three

Table 2. ANCOVA summary data of the high-achievement students

Error	560.68	88	6.37		
Sum	75114.00	92			

***p<0.01*

Table 3. Post-hoc analysis on the posttest of high-achievement students

Comparison			Mean Difference	Standard Error
Experimental Group B	vs.	Experimental Group A	2.59	0.65
Experimental Group B	vs.	Control Group	1.46	0.64
Experimental Group A	vs.	Control Group	-1.12	0.67

groups. Table 2 shows the provision of scaffolds had a significant impact on the learning effectiveness of high-achievement students (f=12.04, p<0.01). It also reveals that the high-achievement students had different learning effectiveness in the three groups with deviation in the provision of scaffolds (f=8.25, p<0.01).

The post-hoc analysis revealed that the high-achievement students in the experimental group B had better learning effectiveness than those in the control group and experimental group A. In addition, Table 3 shows no significant difference between the high-achievement students in the control group and experimental group A.

According to the above results, it can be discovered that providing the scaffold of face-to-face interactions between teachers and students was better than that of online interactions for the high-achievement students

For the students in experimental group A, the support of teachers did not assist them too much because the scaffold provided was in the form of online conversation. It was not so effective because the teachers might not understand the student s' difficulties during the processes of web-based learning, especially when the students had some misconceptions. However, in the face-to-face conversation, the teachers could understand the students' misconceptions and then decide what kind of support to provide. That is why the learning effectiveness was significantly increased.

Low-Achievement Students

The effective samples of the low-achievement students consisted of 28 students in the control group, 31 students in the experimental group A, and 31 students in the experimental group B. Using ANCOVA, the homogeneity of the regression slope was tested (f=0.27, p>0.05), indicating that the homogeneity assumption was met. Through the analysis of ANCOVA, the authors were able to investigate the influences of different approaches on low-achievement students. The deviation F value caused by the independent variables (scaffold-provision difference) was 0.51 (p>0.05), which did not reach the degree of significance. The results in Table 4 show that the learning of scientific concepts by low-achievement students was not affected by the provision of scaffolds.

From the above results, it can be implied that the learning effect of low-achievement students was not influenced by the provision of scaffolds in e-Learning processes, meaning that no matter whether scaffolds were provided or not and regardless of the forms of scaffolds, there was no significant difference in the learning effectiveness of low-achievement students.

According to the above results, it is better for teachers to provide the high-achievement students with face-to-face conversations instead of online discussions. However, providing either scaffold could not help low-achievement students improve further because they all made a remarkable progress in the posttest, meaning that the web-based, adaptive learning system was very effective for low-achievement students and scaffolding was not a factor in influencing their learning.

Development of Learning Responsibility

Another objective of this study was to find out if the web-based, adaptive learning system could help students develop their responsibility for self-learning. There were 18 questions to measure the development of learning responsibility, and the score for each question was from 1 to 5 according to the agreement with the answer. A higher score meant more responsibility was established by the student, and vice versa.

The results showed that both levels of students (t=2.82, p<0.01), no matter whether they were high-achievement (t=2.93, p<0.01) or low-achievement (t=2.71, p<0.01), reached statistical significance in the comparison of the pretest and posttest. More precisely, the students raised their sense of self-responsibility as a result of e-Learning.

E-Learning is different from traditional ways of learning. Given well-organized teaching materials and learning activities, students were more aware of their learning conditions and therefore could do better by themselves to obtain knowledge. Therefore, the e-Learning process was helpful for the development of students' learning responsibility. They could follow the directions to study by themselves and make their schedules to complete the learning activities. For both types of students, the difference was that the low-achievement students preferred to find the answers by themselves, while the high-achievement students wanted to ask teachers for help when they had problems. In both ways, they performed well on the web-based, adaptive learning system.

After the experiment, the authors conducted some semi-structural interviews with a few students to understand their ideas about the web-based, adaptive learning system and its performance. The interview results are summarized as:

I like the way of web-based learning, because I can also do it by myself at home.

I can stop somewhere and repeat studying for several times until I can fully understand the concepts. However, I cannot do it that way in classrooms because I am afraid to ask teachers to slow down their teaching.

Web-based learning is more efficient in raising my learning motivation than traditional classroom learning does.

Table 4. ANCOVA summary data of the low-achievement students

Source	S.S.	DF	MS	*F*	Sig.
Pretest	299.26	1	299.26	24.84	0.01
Deviation	12.33	2	6.17	0.51	0.60
Error	1036.33	86	12.05		
Sum	65606.00	90			

The web-based, adaptive learning system can point out my misconceptions and help me correct them. I can operate the system easily, so I am not afraid of it.

I can learn the concepts of the three states of water efficiently on the system.

Learning on the system is very interesting. I wish teachers in other classes (could) also use the same way in their teaching.

The authors also asked the teachers who were involved in this experiment for their opinions, and they were satisfied with the system because it provided a convenient interface for teachers to design the teaching activities and edit the learning contents. Besides, the system could help teachers identify the misconceptions of students and direct them to suitable learning content to enhance their learning effectiveness. Therefore, it could save teachers' time and effort in providing remedial instructions for individual students.

CONCLUSION

In this study, a web-based, adaptive learning system was designed to investigate the effectiveness of scaffolding on elementary school students with different levels of learning achievement. This study was conducted using a quasi-experimental design and the contents for learning were the scientific concepts of the Three States of Water. According to the experimental results, the findings are:

The web-based, adaptive learning system is effective in helping students acquire the concepts of the Three States of Water. For the high-achievement students, providing scaffolds in the form of face-to-face conversation could significantly enhance the learning effectiveness, which is better than using online interactions or without provision of scaffolds. However, there was no significant difference for the low-achievement students with or without the provision of scaffolds, since they all performed well on the web-based, adaptive learning system. For both types of students, their learning responsibility was significantly improved in the web-based learning environment.

The design of the web-based, adaptive learning system in this study was based on the notion of scaffolding theory and Gagne's learning hierarchy. Because the system provided diagnostic mechanisms in the entire learning processes, it was assumed that the students passing the diagnostic tests would not have any misconceptions. However, the results in posttest showed that some students still had misconceptions about the material. Therefore, teachers should not rely on the diagnostic tools completely. They should use some other assessment tools to see if the students' concepts were correct or not, and then provide appropriate feedback to correct the misconceptions.

If the use of teaching materials and diagnostic tools on the system can be easily transferred to other systems, it will increase the sharing among schools to help more students learn effectively. Moreover, advances in computer and network technologies make it easier for students to learn through networks, and this reduces the workload of teachers in helping students solve their problems. This study was quantitatively oriented so that it might not be enough to discover the details of students' learning statuses and the process of conceptual changes. Future studies can be focused on qualitative methods to understand students' behavior while learning.

APPENDIX: A QUESTIONNAIRE TO MEASURE THE DEVELOPMENT OF LEARNING RESPONSIBILITY

Dear students, The following is a questionnaire to measure the establishment of learning responsibility after web-based, adaptive learning. It is not a test and there are no standard answers. Please read the following questions carefully, and put a check mark inside the space to represent your opinion regarding each question. Grade: □5th Grade □6th Grade — Sex: □Boy □Girl		1. Very likely	2. Likely	3. No opinion	4. Not likely	5. Not likely at all
1.	In the process of learning, I often finish all learning activities by myself.					
2.	In the process of learning, I know clearly whether or not I have understood all learning contents taught in class.					
3.	In the process of learning, I would look for the answers actively to prove that my ideas are correct.					
4.	In the process of learning, I would join the discussion among my classmates actively.					
5.	When discussing with my classmates, I could judge whose ideas are correct.					
6.	I consider that learning is my own responsibility no matter if the result is good or bad.					
7.	In the process of learning, I usually doubt if my own ideas are correct or not.					
8.	If I have difficulty in learning, I will ask for help actively when my teacher does not assist me.					
9.	In the process of learning, I would check on myself to see if my ideas are correct.					
10.	I know clearly how to learn in class.					
11.	If I have difficulty in learning, I will ask for help actively when my classmates do not assist me.					
12.	In the process of learning, I would often request myself to learn more conscientiously.					
13.	During the in-class discussion, I often doubt if the ideas of teachers or classmates are correct or not.					
14.	When I have doubts about the ideas of teachers or classmates, I would search for the answers to prove if they are correct or not.					
15.	I would rather find the answers to my questions than have my teachers or classmates help me.					
16.	After school, I do a self test to see if I have learned whatever was taught in class.					
17.	I think I have to learn actively and positively in order to understand the materials taught in class.					
18.	I make my own learning schedule and follow it accurately.

Chapter 2.8
WebSphere Portal 6.1: An Agile Development Approach

Thomas Stober
IBM Germany Research and Development, Germany

Uwe Hansmann
IBM Germany Research and Development, Germany

ABSTRACT

IBM's Portal technology continues to evolve as a powerful infrastructure for integrating the IT landscape, by presenting it as a consolidated view to the user community. The new capabilities of WebSphere Portal 6.1 are the outcome of a world-wide development team, which focused on this release for the past 2 years. During that time major architectural enhancements have been introduced and a significant amount of code was written. In this article the authors will describe how developers and testers have adopted agile principles to collaborate across the globe. In detail, aspects like an iterative approach, test driven development, budget based prioritization and cross-organization teaming will be discussed. The authors will also cover how "tiger teams" interact with customers by making early code drops available and responding to feedback.

REACHING THE LIMITS OF THE CLASSICAL WATERFALL APPROACH

It ain't what you don't know that gets you into trouble. It's what you know for sure that just ain't so. Mark Twain

Developing market-leading Enterprise Portal products, like WebSphere Portal requires a first-class development team. Far more than 300 developers and test engineers are working for different organizational units and collaborate in very far apart time zones. There are 8 major development sites across the world. The product has dependencies on other IBM products, such as WebSphere Application Server, and is the base for other products, like Lotus Quickr. Further dependencies arise from customer requirements and commitments.

IBM WebSphere Portal leads this wave of innovation, combining the latest user-centric functionality with reliable security and manageability features to meet the needs of the business. The software incorporates extensive Web 2.0 capabilities, allowing companies to fuel social interaction by delivering high-performing, intuitive applications through a rich Web interface. This new release adopts the latest industry-driven standards. It also introduces flexible ways to create and manage Portal sites and content. Many more enhancements emphasize increased utility and flexibility, such as web site management, integration of non-Portal pages as well as step up authentication.

Up to Portal 6.0, the Portal team used to work a classical waterfall approach. Product management captured the requirements and work items for a particular release project, and prioritized them. The project management team assembled a complex project plan with a break down of distinct task assignments for individual developers and testers. There were milestones, test phases, and fixed target dates to achieve the well defined goals. In general there was an analysis and design phase in which content, architecture, and project plan were established. In addition, there was distinct development phase executing the plan, followed by the distinct test phase. In major releases the project plan covered a period of up to 1.5 years.

However the complexity of the technology and especially the growing complexity of the team and time constraints have made it more and more difficult to execute the established plan as scheduled. Future needs and issues are difficult to predict. Each of these distinct phases turned out to be not that distinct and isolated. Instead there were dependencies, loops circulating back to earlier phases in order to adjust. Communication and interfaces between different organizational units are a challenge in large distributed teams. It is extremely difficult to make sure that the right information is made available to the right set of people. Bringing the independently developed pieces together in order to assemble a complex use case requires a significant integration effort, before the overall system reaches a satisfying level of stability. Development and testing were done by separate organizations. While the developers owned the responsibility for design, coding and unit testing, the test organization covered functional and system verification testing.

Typically, unforeseen issues, like a design flaw, or a growing number of bugs beyond the expected, or redirection of resources to other activities, made it necessary to rework the plan. Typically the problems are getting really pressing at the end in the final test phase. At that time, content removal isn't really an option, as the code is already done, although not stable. Delaying the shipment is not a good option, as customers do rely on the promised delivery dates. And sacrificing the quality is not acceptable either. And obviously the costs of fixing problems increase significantly the later the issue is detected. It took a tremendous, costly team effort to solve the situation and ensure that a solid product is still being shipped on time.

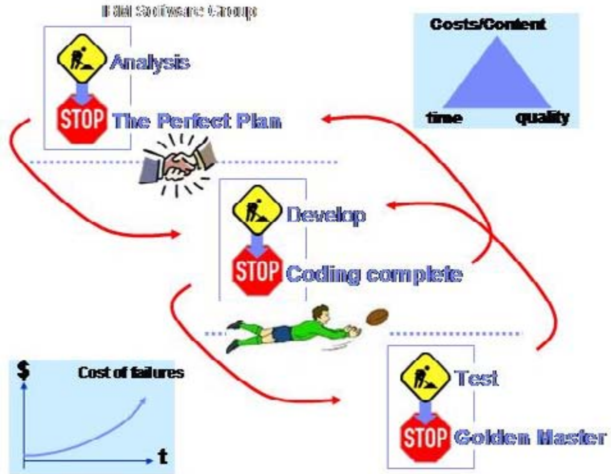
As a result of these experiences, the limits of such a pre-planned waterfall approach became obvious: the classical approach it is too inflexible to react quickly enough to the highly dynamic constraints of a complex product within a large organization (Figure 1).

MOVING TO AGILE SOFTWARE DEVELOPMENT

One of the key reasons, why the Portal team has moved away from a classical waterfall approach used for Portal 6.0, is to gain more flexibility and improve the ability to react to changing constraints. Within a release project, the content needs to be decided as late as possible, while tested and usable pieces of functionality are to be made available as early as feasible.

Another goal is to optimize the flow of human interaction. Intensive collaboration should be

Figure 1. Waterfall approach: it is getting tougher towards the end



fostered across organizational structure - especially between test and development teams and the number of dependencies between different teams should be minimized.

The agile approach, which the Portal team has introduced for Portal 6.1, features 4 key concepts:

- Budget based prioritization and content definition
- Cross-organization teaming Structure
- Iterative development approach
- Test driven development

BUDGET BASED PRIORITIZATION AND CONTENT DEFINITION: REQUIREMENTS AND USE CASES

It is not the strongest of the species that survives, nor the most intelligent; it is the one that is most adaptable to change. Charles Darwin

Which features should be included into a release? Who decides the release content with which level of granularity? For Portal, the product management and lead architects do come up with a first cut of release content by aggregating the customer feedback and high-level requirement into rough focus areas. Each of these focus areas is associated with a budget reflecting the approximate number of developers supposed to be working on that area throughout the upcoming release project. In Portal the designated developers pursuing the same focus area are grouped into a "*Tiger Team*". Each team can span multiple geographical locations and organizational units. The worldwide team acknowledges that the developers of each tiger team are the subject matter experts, and that the "center of gravity" is lowered to allow quicker, better and more optimized decisions directly by the tiger team. This distributed approach scales much better than a central release management deciding on all detailed use cases of the entire release and maintaining a complex overall project plan for all worldwide developers.

For example, it is the responsibility of the developers in each tiger team to translate the given high-level requirements into specific use cases. Each tiger team prioritizes the use cases it intends to deliver in a team charter document. The charter lists highly prioritized use cases, which the team is committing to deliver under all circumstances.

Other items have the disclaimer to be run-at, and will be implemented in the order of priority as time permits. Further items are listed for completeness, but are marked as out-of-scope for the release project. The final scope and timeline of the release project is not yet fully defined when team is being established. To leave sufficient room for agility, it is extremely important that each team is committing only use cases to a limited amount of its team capacity.

Within the constraints of staffing budget, overall release timeline and given high-level requirements, the team can proceed very autonomously with the planning and execution of their activities. Often tiger teams start their work independently of a specific release and drive towards early deliverables outside of an official product. One example is the tiger team, which developed the web 2.0 capabilities for Portal. The team has been inaugurated long before there where any planning activities for a release 6.1. Without knowing yet in which product release their code will eventually be shipped, they delivered early prototypes and presented them at the LotusSphere conference, on IBM's greenhouse site, and as well as part of the Portal 6.1. Beta. Most important, the received customer feedback has been used to improve the web 2.0 capability throughout the project.

Each team is continuously updating and adapting their charter document as well as any other planning document to reflect changing overall constraints, like modified release schedules, dependencies on other teams, or different high-level requirements. Each team's project plan is only specific and confirmed for the next few weeks (one "iteration"), while the rest of the project's duration is tentatively proposed, but subject to change.

The initial budget defined for a Tiger Team is only the first rough guess to help the Tiger Team with some guidelines. During the initial planning and the composition of the overall Release Plan, this budget may very well get adjusted to ensure that the focus items for the release get in with a solid staffing and the required skills. Usually the market is demanding certain features at a certain timeframe and even an agile plan has to commit some minimum of enhancements early up in the cycle.

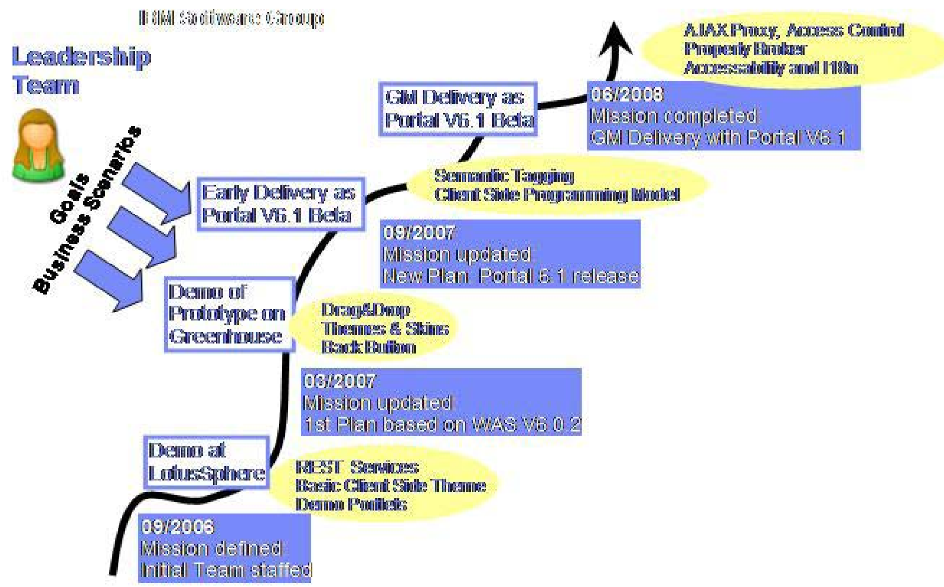
And change needs to be anticipated. For instance, after 5 months of Portal 6.1 development, a change of the underlying WAS version has been decided to meet customer requests: While the original plan has been to ship with WAS 6.0.2, the final product moved to WAS 6.1. This modification affected design documents and implementation significantly, since WebSphere 6.1 introduced an entirely new user management component and had different non-functional requirements. The project duration had to be extended. As the Web 2.0 tiger team did only have little impact by this decision, the team added more use cases to their charter document and spent the extra time until shipment on creating more functionality. In parallel another tiger team began driving the move towards WAS 6.1 (Figure 2).

CROSS-ORGANIZATION TEAMING STRUCTURE: TIGER TEAMS DRIVE INNOVATION

People fail to get along because they fear each other; they fear each other because they don't know each other; they don't know each other because they have not communicated with each other. Martin Luther King Jr.

For each of the focus areas, a tiger team is established with the right set of skills (especially test and development) to fulfill its mission. While the Portal overall organization is traditionally structured into product components, the new tiger teams, which are founded to address certain focus areas, are virtual teams. They focus on their deliverable rather than on existing organizational structures. They span multiple organizations and components, if necessary and possible. Each

Figure 2. Teaming: adjusting goals



tiger team owns the responsibility for planning, designing, coding, documenting and testing of their deliverables. Use cases are implemented by a single team end-to-end and across component boundaries, rather than coordinating multiple parallel changes done by multiple teams. This approach minimizes the cross-team dependencies, hand-offs and task switching. It supports continuous communication and focus on the deliverables.

Most importantly the functional verification testing of the team's deliverables is the team's own responsibility. Continuous testing and direct collaboration between developers and testers improve the process of troubleshooting and bug fixing tremendously as well as creates a very efficient bridge between the development and test organization (Figure 3).

ITERATIVE DEVELOPMENT APPROACH: EVOLVE A SOLUTION AND AVOID THE BIG BANG

Life is what happens to you while you're busy making other plans. John Lennon

It is hard to integrate a significant amount of code at a certain milestone date without causing a major disruption. To avoid painful integration struggle, Portal has adopted an iterative development model. Code is continuously integrated into a common code stream and functionality is brought forward in multiple, small iterations.

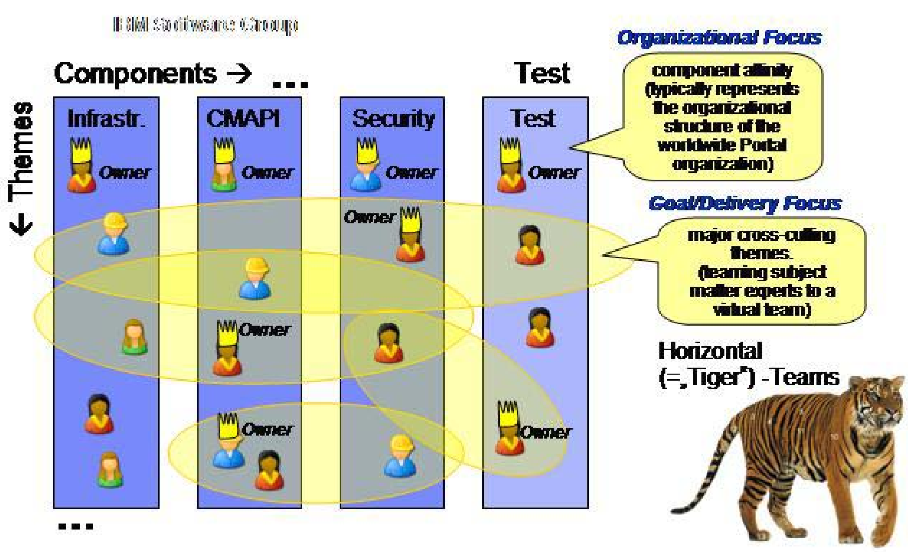
The purpose of an iterative development is nicely summarized in IBM's Agile Manifesto:

Agile Software Development uses continuous stakeholder feedback to deliver high-quality and consumable code through use cases and a series of short, time-boxed iterations.

This implies a few key assumptions:

- The **duration** of an iteration varies between 4 and 6 weeks.
- The **content** of each iteration is defined at the beginning of each iteration. A tiger team picks the top use cases from their prioritized team charter and starts designing and coding those items.
- Throughout the iteration the teams **continuously integrate** their code, documentation and automated test cases into a common code stream. There are daily builds of the entire product. Continuous integration with immediate testing is extremely important to avoid the destabilization which typically arises, when multiple developers add code back into the code stream, which they have accumulated over quite some time.
- Everyone's major goal is to ensure the **stability** of each build. Disruptive changes are to be avoided by all means. Thorough unit testing and automated regression testing is the responsibility of every single developer. The build environment gives some support, by running each code change through a pre-build to surface potential issues prior to the regular production build. It is a mandate to focus on any open issues and bugs first, before proceeding with the development of new functionality ("Stop-the-line" concept).
- Part of the iteration is **functional verification testing** within the tiger team. Only tested and working use cases are accepted as a delivered achievement.
- **Performance** and **documentation** are further aspects to be covered within the iteration.
- In order to be able to implement a use case within an iteration it is extremely important to break larger user stories into **smaller, digestible chunks**.
- Iterations are **time-boxed**. They have a defined start and end date. Usually all tiger teams operate on the same iteration schedule.
- At the end of each iteration, all tiger teams are jointly demonstrating their deliverables

Figure 3. Teaming: theme and component matrix

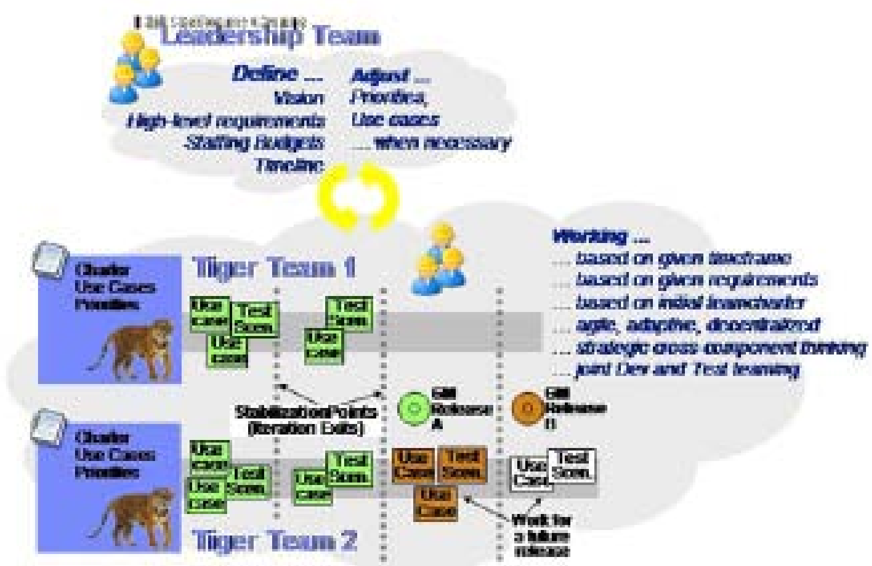


to the worldwide team. This demo event is referred to as "**Integration Fest**" and is performed using a regular build. The demo should proof that a stable, tested, and usable version of the product has been accomplished and that this version can be delivered to exploiters of WebSphere Portal.

- At the end of an iteration, the tiger team needs to proof that it has executed the agreed test cases, and that no defects are open. This will also be validated by Performance and System Tests that immediately follow each iteration.
- **Feedback** by the exploiters is incorporated into the next revision of design and plan.

Throughout the release, the teams maintain their prioritized list of use cases which they tentatively want to address in the foreseeable future, and they have elaborated a rough high level design outlining all items of their focus area. But only the current iteration is being precisely planned and detailed into work items as well as low level use case descriptions (Figure 4).

Figure 4. Iterations: executing the release project



TEST DRIVEN DEVELOPMENT: GAIN TRUST AND QUALITY FROM DAY ONE

If anything can go wrong, it will. Murphy's Law

As mentioned above, the collaboration between development and test is absolutely key for achieving a usable level of quality throughout the release project.

There are several different test considerations:

- **Build Verification** and Smoke Testing is done for each product build. It is partially automated and covers the very basic product capabilities.
- **Functional verification testing** is done within each Tiger team and is an integrated part of ANY development activities. Design documents with use case descriptions already consider test scenarios and test planning. The testing is includes automated regression testing.

- **Extended Functional Verification Testing** is executed by a dedicated test team in parallel to the ongoing iterations. Main focus is extending platform coverage and adding more regression testing.
- **Performance testing** is going on throughout the release project. Goal is to identify performance regression, but also to help the development teams with analyzing the performance bottle necks in the implementation.
- **System Verification Testing** is done in parallel to the ongoing iterations as well. This testing covers long running test scenarios as well as complex environment such as cluster setups. Goal is to identify potential memory leaks or instabilities early.
- Once the last iteration is completed, a "**Release Closure**" phase is appended, in which the test teams conduct further regression testing. There is especially a focus on system verification testing.

THE ISSUES AND PAIN POINTS

No man ever steps in the same river twice, for it is not the same river. Heraklit

In summary, agile development practices proofed to improve the flexibility of the release project and especially the efficiency within the development and test organization. Nevertheless the move from the waterfall model towards tiger teams and iterations has been a challenging journey. Portal has mixed and matched suitable ideas from the palette of known agile techniques and concepts. Part of this journey has always been to reflect the applied techniques and adapt the progress. Learn as you go. Each project is different. Each team has different needs to perform. Continuous feedback from the overall team triggered the continuous improvement of Portal's agile approach.

There have been key challenges to resolve, but there is no generic solution, which fits all. The experience made by WebSphere Portal can be summarized as a set of guidelines and considerations:

Finding the right **balance between flexibility and planning** is difficult. Do not waste time with planning exercises on a too granular level of detail. The project status 6 months from now is not predictable. Making early commitments will narrow down the possible options for your future.

Flexibility is good, but no for free! Deferring decisions will require additional investment, as some simplifying assumptions cannot be made yet. Planning and documentation are needed to document agreements and commitments, to describe the architecture, and to specify interfaces. Don't use "Agility" as an excuse for lack of planning and design preparation. This is quite similar to purchasing plane tickets: If you decide late and want full flexibility, the airfare will be higher compared to early bookings for a fixed date.

In the context of the Portal product, key architectural decisions, like choosing the underlying WAS version or selection of code streams in the source library system, are constraints which are rather expensive to hold off. Defining the major focus areas of investment within the release project and a rough timeline is crucial. It needs to be done early, whereas finalizing the exact feature scope or the shaping the exact out-of-the-box functionality can be done rather late. The first iterations will give a well-founded assessment of progress, status, quality and the remaining capacity of the teams. That kind of information will be a much more reliable baseline for an ongoing fine grained planning.

It is important to **break down big pieces of work in smaller use cases**, which can be implemented and tested within a single iteration. This helps to create frequent and measurable results, instead of piling up a lot of unfinished work. It also helps to monitor and understand progress – an essential information for fine tuning the planning of the upcoming iteration.

You need to **plan for change**. Therefore any planning or commitment needs to ensure, that there is sufficient buffer to accommodate the unforeseeable events. It is very useful to only commit to few, most important use cases initially. The team can add more, once the product is getting shape and there is less ambiguity in the planning constraints.

Test automation is crucial. If there is no extensive coverage of automated functional verification tests, it is impossible to avoid regression problems, when the next set of use cases is implemented in a subsequent iteration.

Agile Software development is demanding openness for change and flexibility from everyone. Agile needs commitment by the entire organization in order to work out:

Each **Tiger team** is accountable for its results. Everyone needs to understand what other team members do. Teams need to keep risks in mind, take over responsibility and be prepared to come up with mitigation plans quickly. Tiger teams span organizational structures and location. They drive customer oriented, end-to-end use cases with less gaps in between. They think out of the box rather than being cramped by a component centric point of view. This is the key strength of Portal's agile approach.

The **leadership team** needs to trust and empower the teams. They need to give guidance by communicating a well defined overall Vision, high level requirements and a rough timeline in which deliverables are expected. And they need to encourage a common team spirit within each tiger team.

Agile Software Development is a lot about philosophy. As mentioned above, there is no general rule, no generic process. Mix and Match of various techniques is the right way to go, as long as you accept that change is part of your plan. Based on the experiences outlined in this article, the authors have published a comprehensive book covering the basics of agile software development. In particular, this book emphasizes best practices for large software development projects.

ACKNOWLEDGMENT

SUMMARY

The adaptation of agile software development has been a quite challenging and disruptive exercise. Most important has been the ability to break down complex development items into manageable use cases, which can be designed, scheduled, implemented, tested and tracked easily. The major challenge has been to get the ongoing support from the key players in the organization. As described above, the move towards a more distributed leadership model, as well as letting go of centralized control has been controversial throughout the project. But in the end, agile development has been a convincing approach, despite all the issues and struggles which had to be resolved during the project. Its flexibility turned out to be especially supportive for such a large development organization. Future Portal releases will continue to evolve agile development and further improve and adapt the process to meet the team's requirements.

Chapter 2.9
Adaptation and Recommendation in Modern Web 2.0 Portals

Andreas Nauerz
IBM Research and Development, Germany

Rich Thompson
IBM T.J. Watson Research Center, USA

ABSTRACT

In this paper, we propose a generic recommender framework that allows transparently integrating different recommender engines into a Portal. The framework comes with a number of preinstalled recommender engines and can be extended by adding further such components. Recommendations are computed by each engine and then transparently merged. This ensures that neither the Portal vendor, nor the Portal operator, nor the user is burdened with choosing an appropriate engine and still high quality recommendations can be made. Furthermore we present means to automatically adapt the Portal system to better suit users needs.

INTRODUCTION

In recent years Enterprise Information Portals have gained importance in many companies. As a single point of access they integrate various applications and processes into one homogeneous user interface. Today, typical Portals contain thousands of pages. They are no longer exclusively maintained by an IT department, instead, Web 2.0 techniques are used increasingly, allowing user generated content to be added to Portal pages. This tremendous popularity and success of Portals, has its downsides: Their continuous growth makes access to relevant information increasingly difficult. Users need to find task- and role-specific information quickly, but face information overload and feel lost in hyperspace. The huge amount of content results in complex structures designed to satisfy the majority of users. However, those superimposed structures, defined by Portal authors and administrators are not necessarily compliant to the users' mental models and therefore result in long navigation paths and significant effort to find the information needed. The likelihood of a mismatch between a user's mental model and the administrator's mental model increases as more users access the Portal. This becomes even worse, once user generated content is added, where the structure may not follow the design the administrator had in mind. In addition, the more content a Portal offers, the more likely it becomes that users are no longer aware of all the resources available within it. They might thus miss out on resources that are potentially relevant to their tasks, simply because they never come across them. Thus, on the one hand, users obtain too much information that is not relevant to their current task, on the other hand, it becomes cumbersome to find the right information and they do not obtain all the information that would be relevant. Users therefore need the Portal to assist them in finding relevant information in an efficient manner.

Generally this type of problem falls in the domain of recommender systems and numerous such systems have been proposed in recent years. Each of these can recommend relevant items for specific applications or when certain data characteristics are met, but none meet the breadth needed to address assisting a Portal user. In this paper we will outline a generic recommender framework into which specific recommendation engines can be installed. The framework decides which engines are likely to produce relevant recommendations for any particular situation and how multiple results sets are combined when multiple engines are invoked. The framework comes with a number of preinstalled engines and basic configuration for using them. This alleviates the burden on the Portal administrator relative to the initial configuration and transparently leverages the best engines for assisting the user in accomplishing their task.

In addition to providing users with recommendations we also adapt the Portal's structure automatically to better satisfy users needs.

Most of our solutions for adapting and recommending content are based on user and context models that reflect users' interest and preferences and on annotations of resources provided by users. For instance, we adapt a Portal's structure (e.g. navigation) and provide recommendations to be able to reach content being of interest easier. We recommend background information, experts and users with similar interests.

In the following we will first give an overview of related work. Next, we outline which information is needed to achieve our goals, and, more importantly, how to obtain the necessary information. Here the focus lies on collecting information about users (and their interests, preferences and thus needs) and the resources they interact with. We will show that a mixture of automated information extraction and user provided information is currently the most realistic approach. Afterwards we demonstrate how this information can be exploited to either adapt the Portal or to issue reasonable recommendations.

RELATED WORK

The explosive growth of information on the Web has led to the development of recommender systems [Resnick and Varian, 1997]. Recommender systems are a personalized information filtering technology used to either predict whether a particular user will like a particular item (prediction problem) or to identify a set of N items that will be of interest to a certain user (top-N recommendation problem). In recent years, recommender systems have been used ina number of different applications such as recommending products a customer will most likely buy; movies, TV programs, or music a user will find enjoyable. An excellent survey of different recommender systems for various applications can be found in [Schafer et al., 1999].

Over the years, various approaches for building recommender systems have been developed [Ramezania et al.,2008]: Collaborative Filtering (CF) recommenders use social knowledge - typically ratings of items by a community of users to generate recommendations. Content-based (CB) recommenders use item features to recommend items similar to those in which the user has expressed interest. Knowledge-based (KB) recommenders use domain knowledge to generate recommendations. Hybrid recommender systems combine two or more techniques to gain better results with fewer drawbacks.

The recent competition to improve the recommendation system employed by Netflix has shown the value of applying multiple recommendation engines (a combination of an algorithm and a specific configuration) to be a problem. The Progress winner employed many variants [Robert M. Bell and Volinsky, 2007], each of which was designed to do best in certain circumstances, such that the overall quality of the generated recommendations was improved. This demonstrates the value of multiple engines within a single domain and the effect is multiplied when multiple application domains are accessible through a single system, as is common for Portals.

More specifically, regarding the recommendation of expertise, systems that help to find experts are called expertise finders or expertise location engines [Zhang and Ackerman, 2005]. A general architecture for recommendation systems that allow locating experts is described in [McDonald and Ackerman, 2000]. More specifically Streeter et al.present Who Knows, a system which recommends experts having knowledge in specific topics based on profiles created from observing the documents they have selected and worked with previously [Streeter and Lochbaum, 1988].Newer systems that use information about social networks to find experts are e.g. [Kautz et al., 1997].

Providing background information or interlinking information pieces is based on the ability to either allow users or programmatic, automated, annotators to annotate information pieces. We have described the first approach in [Nauerz and Welsch, 2007] already. The second approach is based on information extraction from unstructured machine-readable documents. Although the approach to perform the extraction often differs, most papers in this area regard information extraction as a proper way to automatically extract semantic annotations from web content. Most of these systems are based on machine learning techniques, e.g. [Dill et al., 2003].

With respect to adaptation systems, systems that build and apply user and usage models to adapt web sites to the user's context (interests, preferences, needs, goals, etc.), a lot of research has already been performed in the field of adaptive hypermedia [Brusilovsky, 2001]. One possible approach to derive those models and enable adaptation is to analyze user access data, as Perkowitz and Etzioni [Perkowitz and Etzioni, 1997] propose. Projects in this context include PageGather [Perkowitz and Etzioni, 2000], Letizia [Lieberman, 1995] and WebWatcher [Joachims et al., 1997]. Especially with respect to navigation adaptation Smyth and Cotter [Smyth and Cotter, 2003] describe an approach to improve navigation in mobile Portals significantly.

INFORMATION ABOUT USERS, BEHAVIOR, AND RESOURCES

From a conceptual point of view (cp. fig. 1) Portals are comprised of various resources such as pages and portlets (artifacts residing on pages delivering content). These resources are arranged based on Portal models, often initially created by some administrator with the aim to satisfy the largest set of users and not the preferences of each single user. We therefore need information about individual users (or groups of users) and their behavior as a basis for both adaptation and recommendations. We apply different techniques such as web mining to construct user models reflecting users interests and preferences; we use information from their static profile (native language, home country, working location, age, etc.), their interaction behavior (pages and portlets they work with; tags they apply to resources), and their social network to derive knowledge about their needs. We observe the context (date, time, location, ...) in which they interact to partition the user model in so called profiles like private or business. Additionally, we need enriched information about the resources available in the system. We illustrate how we extract information pieces of certain type in order to provide background information by connecting to external sources and to interlink them in order to issue recommendations.

Extracting Information about Users

User Model

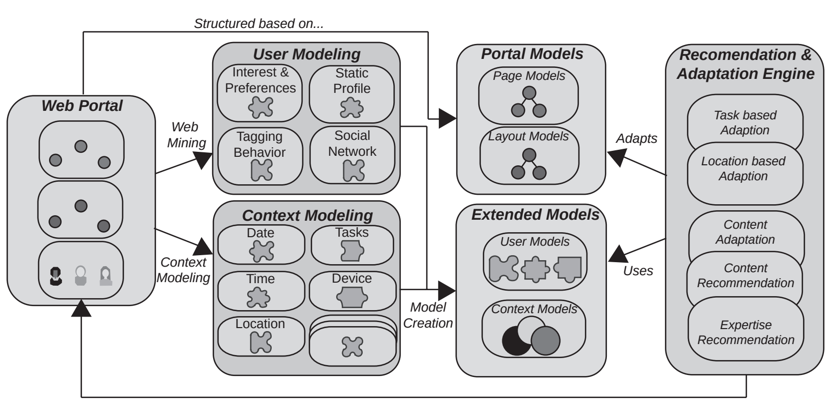
In order to perform reasonable adaptations, or to provide users with recommendations, we need to understand users' interests and preferences. Therefore we construct user models reflecting their behavior. We use static information from users' profiles (describing their age, native language, etc.), as well as dynamical information which we retrieve via web usage mining.

Web Mining [Liu, 2006] is the application of data mining techniques to discover (usage)-patterns within web data. Web usage mining is the extraction of usage patterns from access log data to model certain aspects of the behavior of users. Our system has been incorporated into IBM's WebSphere Portal. Analyzing its logs reveals information about, among other things, several interesting events, e.g. when pages (or portlets) are created, read, updated or deleted, when pages (or portlets) are requested,when users are created, updated, deleted and many more.

Analyzing the log allows to understand which pages and portlets a user typically works with. Obviously, the user model must allow the calculation of the utilization of pages and portlets from the historical data available. We do this by measuring how often a user interacts with certain pages and portlets. Of course, we also consider interactions that occurred recently to be more important than interactions that occurred in the past and we hence apply time-weighting factors when calculating the utilization of pages and portlets based on the target hits they received.

More generally, we apply techniques from the area of frequent set mining [Liu, 2006] to analyze the usage of pages and portlets. We use the Apriori algorithm [Agrawal and R., 1994], a standard association rule mining algorithm, to determine items, such as pages and portlets that co-occur frequently. We apply the GSP algorithm [Srikant and Agrawal, 1996], a standard sequential

Figure 1. Conceptual overview



pattern mining algorithm, to determine sequences of items, such as pages and portlets, that co-occur frequently. Comparing the itemsets even allows to find users behaving similarly.

Tagging Behavior Analysis. In our previous work we have incorporated a tag engine into IBM's WebSphere Portal allowing users to annotate resources such as pages, portlets and users. Analyzing (and comparing) the tagging behavior of users allows for refining the user model. The general assumption is that tagging expresses interest in a resource.

Social Network Analysis. Finally, the analysis of users' explicit contacts allows to determine users' interests and preferences, too. The assumption is that the fact that users directly know each other can be an indication for related job roles and hence for sharing similar knowledge.

Context Model

Focusing on user models only neglects the context users are currently acting in. Hence, these could be regarded suitable models, only, if the role, the interests and preferences of users will not change too much over time. In reality, a user's needs usually change if their context changes. For example, a user in the process of planning a business trip will need resources that provide information about hotels, rental cars, and flights. When the same user returns to their tasks as a project manager, a completely different set of resources is needed. Of course, interests and preferences will be different in these roles and access to a different set of resources (pages, portlets, etc.) will be needed.

Our solution allows single users to have several context profiles between which either the system switches automatically, based on context attributes being observed (date, time, location, etc.), or the user can manually switch. New profiles can be defined using a profile management portlet which allows to specify the initial settings of a profile (which theme to use, which skin to use, etc.) and to associate it with a set of context attributes (date, time, location, etc.) which define when it should become active.

Our adaptation and recommendation components utilize both the information stored in the user and context model, to perform their operations (i.e. to adapt structures such as the navigation). Technically, the user model is partitioned in a separate partition for each context profile available in the context model. To determine the best matching profile, the system continuously observes a set of defined context attributes. Users always have the option to outvote the system's decision and to manually switch to another profile. As only one context profile can be active at one specific point in time, whatever people do only influences the user model partition associated to the currently active profile. For example, if the currently active profile is trip planning, all the navigation behavior, does not influence the user model partition associated to the profile project management.

Extracting Enriched Information about Resources

To extract enriched information about the resources, we currently allow for the usage of three different mechanisms:

Automated Tagging. Here the system analyzes markup generated by the Portal to find occurrences of identifiable information pieces of certain types such as persons, locations, etc., and wraps these into semantic tags. We have integrated the UIMA framework 1 and written customized analysis engines able to identify such information pieces. Semi-automated Tagging If the system cannot unambiguously identify the type of an information piece it still allows users to mark it and tell the system of what type it is. We call this process semi-automated tagging. For instance, if we find a fragment "Paris H. was sighted leaving a Hotel in Paris" it becomes difficult for the system to determine whether Paris is a name or a location. The user can then mark the corresponding information pieces and tell the system their type.

The information pieces are then wrapped into a semantic tag exactly as outlined before.

Manual Annotating Moreover, our system allows semantically tagged information pieces to be annotated manually again. For example, if the name of three persons Alice, Bob, and Charly often appear somewhere in the Portal system, e.g. in blog- or wiki portlets, our system automatically determines these fragments to be of type person, wraps them into semantic tags and allows for advanced interaction with these information pieces. Our tag engine allows these enriched fragments to be annotated e.g. with the term project-x which indicates that all three persons are somehow related to this project. This means that the options for manual annotating allow for a finer-grain categorization of information pieces.

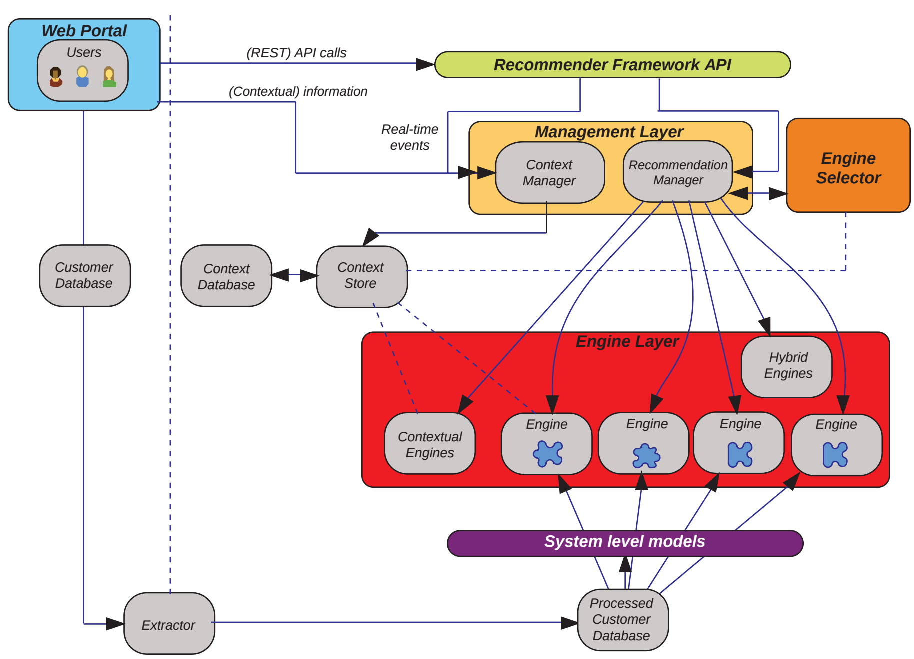
Supporting Framework

Figure 2 shows the architecture of our recommendation framework. The main components are an extractor framework, a management layer, an engine selector and an engine-hosting layer.

The extractor component manages getting incremental changes from the customer's underlying databases and making them available for processing into the recommendation models used by the deployed engines. While there are some cases of reusing shared (or system-level) models, most recommendation engines build their own models and optimize these for rapid recommendation generation. As a result, each engine's configuration will typically register a processing module with the extractor in order to receive and deal with each incremental update to the customer's data. By centralizing the extraction, impacts on the customer database are minimized as is the effort need to provide access to a new type of data source.

There are two components which are instrumented through the page and page-support mechanisms. The first of these manages contextual information. Some contextual information is already gathered elsewhere (e.g. from information

Figure 2. Recommendation framework



already logged), as discussed in Section 3.1, and this is accessed from those sources; for example, the pages activated. Other contextual information is application specific and are sent as contextual events into the system; for example, dynamically presented information has been accessed. This information is timestamped and placed into a central store which system's components, usually the recommendation engines, can use when responding to a request.

The other part instrumented on the page is requesting recommendations be generated. Each page could be displaying multiple different types of recommendations (experts, similar people, pages, portlets, etc). These are requested, normally using an AJAX request, and displayed in whatever manner the user experience prefers. The system provides dojo widgets which can be leveraged for quickly adding recommendations to a page. These include a data widget which manages requesting recommendations, parsing the response into javascript objects and providing easy access to these objects. It also includes both a simple display widget for showing any one recommendation type (e.g. experts) as an HTML list and a more complex widget that displays each recommendation type in a separate tab of a tabbed pane construct.

When the system receives a request for recommendations, it examines the request to determine what recommendation engines should be used to generate the response. The management layer delegates this decision to an engine selector and then invokes the identified engines, passing them both the request parameters and a reference to the active context store. The engine selector remains an area of active research with the simplest variant being a rule engine. It is expected that this research will realize a significant improvement by having the engine selector specify both the engines to use and how their results are to be combined. Each engine will use whatever portion of the supplied information is appropriate to their algorithm in order to generate their response. Section 5.2 discusses some of these engines, including those supplied along with the base configuration. The recommendation manager will then combine the responses from all invoked engines and provide a single, unified response to the client.

The recommendation engines are hosted by a layer that uses Inversion of Control [Wikipedia Foundation, 2008] concepts to define engine instances and the configuration parameters to apply to each instance. Often the referenced components are wrappers that map our internal API and data structures to the ones used by the actual engine. For example, a wrapper for the open source collaborative filtering engine Taste [Apache Foundation, 2008] has been used to incorporate this externally developed engine. Due to the nature of the design, we expect similar wrappers to be easily developed for other external engines. This architecture allows very different engines to be deployed (collaborative filtering, content-based, knowledge-based, etc.) and work independently of each in a manner that will together generate improved results for the user. It also makes it easier to add recommendations to a website as many of the issues of accessing engines are provided by the framework.

EXPLOITING THE MODELS FOR ADAPTATION AND RECOMMENDATION

Now that we have described which information about the Portal resources and users are available to our system, we can explain how this information is used to improve the user experience with the Portal. We propose methods to adapt the content, to recommend content, to offer additional information and to recommend experts. In the following, more details about the approach are given.

Adaptations

Within the context of this project we have come up with different solutions allowing for adaptation and recommendation of the Portal's structure. Most of them focus exemplarily on the adaptation of the navigation.

Manual Adaptation. First, options to manually adapt the navigation have been introduced. Therefore we implemented specialized portlets that allow each single user to generate her own navigation matching her preferences best. The first portlet allows users to generate their own navigation by hiding irrelevant nodes (pages) and by reordering nodes being part of the navigation in order to reach relevant nodes more quickly. The second portlet allows users to record paths (i.e. sequences of pages) traveled often. These recordings can be recalled later and navigated through by just clicking previous and next links. The recordings can even be exchanged with other Portal users which allows experts to record common paths for their colleagues.

Automated Adaptation. Automated adaptation relieves users from generating an optimized navigation manually. We leverage our user models to understand users' needs.We use a structure reordering algorithm to rearrange pages: more important nodes are promoted to better navigational positions, less important ones demoted or even hidden. Continuous adaptation, based on the most current user models available, guarantees that the navigation permanently fits the users needs as best as possible. As soon as users' behaviors change their user model changes, too and hence the navigation provided. We leverage our user models to understand users' needs. We use a structure reordering algorithm to rearrange pages: more important nodes are promoted to better navigational positions, less important ones demoted or even hidden. Continuous adaptation, based on the most current user models available, guarantees that the navigation permanently fits the users needs as best as possible. As soon as a user's behavior changes, their user model is updated and hence the navigation provided takes into account the new behavior.

Automated Recommendation. Especially users that navigate according to the aimed navigation paradigm [Robertson, 1997] will not like automated adaptations because of its aggressiveness. Automatic provisioning of recommendations avoids the permanent restructuring of the navigation while still providing users with shortcuts. We blend-in recommendations into the Portal's theme that provide users with reasonable shortcuts to relevant pages. These shortcuts are dynamically generated depending on the current navigational position. Our recommendation system applies a MinPath algorithm [Anderson et al.,2001]. We try to predict shortcuts to nodes that are far away from the current node but have a high probability to be navigated to. The probability itself is calculated based on Markov chains as described in [Anderson et al., 2002; Smyth and Cotter, 2003].

Context-adaptivity. As mentioned above, users may have several different context profiles. By switching to a different profile, the Portal will be adapted accordingly based on the information contained in that profile.

Recommendations

In our framework, we have developed a set of recommender engines that provide recommendations to background information and related content either by displaying shortcuts to relevant pages or by showing widgets/portlets containing links to relevant information. Currently these engines come in two flavors (though the framework is not restricted to just these flavors): recommender engines based on the user model and collaborative filtering recommenders. Further-more, both types of recommender engines can leverage the context model in order to provide recommendations with respect to the current activity of the user.

Recommenders Based on User Model

The first category of recommender engines provide recommendations to related content based on the information stored in the user model, which reflects static information about the user (like language preferences, age, location, etc.) as well as navigation behavior of individual users, including their favorite pages and routes through the entire navigation topology of the Portal. Recommendations are generated based on certain properties of the user model and the resulting recommendations can be used to suggest forward navigation links or to automatically change the navigation topology in order to reveal the interesting pages and hide irrelevant content.

Collaborative Filtering Recommenders

In contrast to the recommenders that provide recommendations based on the analysis of the history of a particular user, the collaborative filtering (CF) recommenders provide recommendations based on the analysis of the behavior of multiple users. The collaborative filtering engines first try to identify the users that have similar tastes and behaviors to the current user and then retrieve the items that these users liked most and recommend them to the current user. The CF-based recommendations help to discover new and unknown content items that might be of interest for a particular user.

The CF-approach can be applied in numerous ways; for recommending navigation links, the set of similar users might best be chosen based on having a similar set of target hits as the current user. The CF-approach would then recommend those pages for which these users also have high target hits, but which the current user does not. In domains such a catalog systems (e.g. movie sales/rentals), preferrably the ratings of the user vs other users is used to generate the recommendations. In the absence of explicit ratings, previous history and the items viewed within the current interaction session can be used as implicit forms of ratings.

Other Recommenders

While not included in the current set of supplied recommendations engines, the framework takes into account that other recommendation strategies exist (and continue to be invented). At a minimum these include Content-Based recommenders and various different approaches to Knowledge-Based recommenders.

Context-Based Recommendations

So far we have described only the recommendations based on the navigation history of individual users and commonalities of interests among multiple users without respect to the context in which the users are acting. However, the initial recommenders of both categories can also access the context model in order to provide recommendations that could be especially relevant in certain situations. Our recommendation framework allows single users to have several context profiles. These profiles can be recommended to the user automatically by the system or users can switch between them manually.

New profiles can be defined using a profile management portlet which allows specifying the settings of a profile (which theme to use, which skin to use, which navigation topology to display etc.) and to associate it with a set of context attributes which define when it should become active. Whatever people do only influences the models associated to the current active profile. If the currently active profile is business, all the navigation behavior, all the usage behavior of Portal pages etc. does only affect the models associated to this profile, but never influences the modelsassociated to the private profile. For the determination of the best matching profile the system continuously observes a set of defined context attributes. Users always have the option to outvote the system's decision and to manually switch to another profile. A learning mode allows users to let the system learn about their needs and tastes in a specific new context.

Recommending Background Information

As said, in today's Web 2.0 world content is created by entire user communities. Different users use different terms to describe the same things. Some terms might be well-understood by most users, some might not.

Thus looking up terms is needed more frequently and becomes a tedious task. But when reading web sites, users want background information at their fingertips. If they do not understand what an abbreviation or a term stands for, who a certain person actually is, or, where a certain city is actually located, they want to be able to retrieve this information as easily and quickly as possible. They do not want to fire up a search engine to search for another site from which they could probably get the information they want, but rather be provided with that information directly, in-place. We provide an environment which unobtrusively enriches the information pieces to allow for such look-ups.

Figure 3 shows our system in action: it illustrates how a fictious person name (John Doe), a location (Stuttgart), and a currency have been identified within a text fragment residing in a portlet and are visualized to the user. Pop-ups provide the users with background information.

Recommending Related Content

Analyzing occurrences of semantically tagged information pieces also allows us to recommend related content. For instance, if the term WebSphere Portal is identified in a news portlet and hence semantically tagged as a product name our system would provide users with background information about WebSphere Portal probably by linking to the product site. But, within a Portal system, the same term might occur at many other places, e.g. in a wiki portlet where users have posted some best practices, tips and tricks when working with this product, in a blog where users have commented on the product and so forth. We track all occurrences and recommend (an appropriate subset) of them as related content as soon as the user interacts with one single occurrence.

This can even be taken one step further. As mentioned above, we allow users to annotate already semantically tagged information pieces. This way we can recommend related content not only by having identified "exactly matching" occurrences of semantically tagged information pieces, but also by having identified similarly annotated, but differently semantically tagged, information pieces. For example, if Alice, Bob, and Charly have been annotated as persons and a user tagged them with the term project-x to ex-

Figure 3. Recommending background information and related content

press their relationship to this project, this allow us to recommend other users of the community as related ”content” as soon as one user is clicked, just because they all seem to be assigned to the same project. This can be useful, e.g., if a user has a question to something he is reading about and tries to contact the author whose name is given but who is currently unreachable. Recommending related users allows him to easily determine backups that could probably help him, too.

Figure 3 shows how we can recommend related information for the detected information pieces Stuttgart and John Doe (other people probably working in the same team, on the same project etc.).

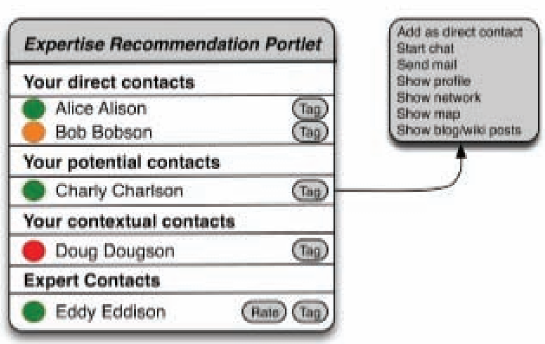
Recommending Expertise

As said, user models also tell us about with which pages and portlets a user is typically working with.

The first assumption is that users working with certain pages and portlets more often have more expertise about how to use them than other users have. The second assumption is that users working with the same pages and portlets more often have a similar behavior and hence interests and preferences.

For example, if users A, B, and C often work with the pages and portlets underneath the page entitled My News we can, on the one hand assume that they have knowledge about how to deal with the pages and portlets provided here, and, on the other hand assume that they have similar interests as they do similar things. A user D accessing the same pages and portlets rarely can then be presented with A, B, and C as experts when dealing with the information and services provided. Therefore we have designed a specialized portlet (cp. Figure 4) that can be accessed from every page (on demand).At the top of the portlet contacts are listed which have explicitly been added as such by the user. Adding contacts explicitly demands sending a request to the contact to be added which, in turn, can accept or reject this request. The second section displays contacts the system has determined to behave similarly which can be derived by comparing user models. These are contacts the user might want to get in touch with, generally to share knowledge. The third section displays contacts currently performing similar actions within the Portal (e.g. viewing the same page or working with the same portlet). The last section at the bottom of the portlet displays contacts the system has determined to be experts with respect to the (content) area currently being visited by the user.

Figure 4. Recommending experts



The list of users displayed in the last three sections dynamically changes as the current user interacts with and navigates through the Portal, while the first section always displays a static list of contacts. The portlet provides several functions to interact with the contacts being listed:

People-awareness ensures that users contact other users being available more likely than the ones being unavailable. To ensure that users do not disturb the latter, e.g. during meetings, an online status is displayed for each single user displayed as part of the portlet. Tagging and rating functions allow contacts to be tagged, expert users even to be rated. This allows for a user-driven categorization of the contacts. Additionally, rating allows assessing how helpful an expert was. Profiles display information about the contact's official job role, his position within the organization's hierarchy, his address, and so forth. Social network visualization functions allow the user to see a visual depiction of how his contacts are related to him and to each other. It presents a graph which nodes are the user's contacts. It allows users to determine which users are part of the same team, who personally knows whom and hence allows e.g. to find backups for persons being currently unavailable easily. It is also possible to see contacts as marks on a GoogleMap.

CONCLUSION AND FUTURE WORK

In this paper we have presented a solution for adapting and recommending content and expertise to satisfy Portal user needs and improve collaboration among them. We have shown means to collect the necessary information and to adapt the navigation structure, to recommend background information, related content and expertise.

We have presented an extensible, pluggable, recommender framework which allows several recommender engines, that can even apply different recommender technologies, to be used transparently.

All the approaches proposed in this paper have been implemented and integrated into IBM's WebSphere Portal.

For evaluation purposes we have set up a demo system and performed some initial surveys. 100% of all participants (all computer scientists, male, 25-50 years old) regarded the system as useful. Of course, we plan to perform more systematic evaluations within the next months.

Future work includes the extension of our recommendation and adaptation techniques.

Chapter 2.10

Context-Aware Applications for the Web: A Model-Driven Development Approach

Florian Daniel
University of Trento, Italy

ABSTRACT

Adaptivity (the runtime adaptation to user profile data) and context-awareness (the runtime adaptation to generic context data) have been gaining momentum in the field of Web engineering over the last years, especially in response to the ever growing demand for highly personalized services and applications coming from end users. Developing context-aware and adaptive Web applications requires addressing a few design concerns that are proper of such kind of applications and independent of the chosen modeling paradigm or programming language. In this chapter we characterize the design of context-aware Web applications, the authors describe a conceptual, model-driven development approach, and they show how the peculiarities of context-awareness require augmenting the expressive power of conceptual models in order to be able to express adaptive application behaviors.

DOI: 10.4018/978-1-60566-290-9.ch003

INTRODUCTION

The evolution of the Information Technology in the last years has seen the World Wide Web transforming from a read-only hypertext media into a full-fledged, multi-channel and multi-service application delivery platform. Current advances in communication and network technologies are changing the way people interact with Web applications. They provide users with different types of mobile devices for accessing – at any time, from anywhere, and with any media – services and contents customized to the users' preferences and usage environments. More and more users themselves ask for services and applications highly tailored to their individual requirements and, especially due to the increasing affordability of new and powerful mobile communication devices, they also begin to appreciate the availability of ubiquitous access. In order to cope with the growing demand for novel, user-centric application features, such as adaptivity and context-awareness, appropriate development methods for Web applications are required.

Adaptivity is increasingly gaining momentum in the context of modern software systems. Runtime adaptivity provides highly flexible and responsive means for the customization of contents and services with respect to the user's identity. Varying device characteristics in mobile and multi-channel computing environments can be adequately taken into account and leveraged by means of adaptive software designs, whose development is facilitated by the availability of standardized communication protocols (e.g. HTTP) and markup languages (e.g. HTML or WML), supported by most of today's mobile devices. Multi-channel deployment does no longer require completely different, parallel design approaches and rather represents a presentation issue on top of unified engineering solutions.

But adaptivity may also enable an application to take into account a wider range of properties describing the interaction between the user and the application, thus paving the way for context-awareness. *Context-awareness* (Dey & Abowd, 2000; Schilit & Theimer, 1994) is often seen as recently emerged research field in information technology and in particular in the domain of the Web. From the perspective of application front-end development it can however be interpreted as natural evolution of personalization and adaptivity, addressing not only the user's identity and preferences, but also his/her usage environment. Personalization has already demonstrated its benefits for both users and content providers and has been commonly recognized as fundamental factor for augmenting the efficacy of the overall communication of contents. Context-awareness goes one step further in the same direction, aiming at enhancing the application's usefulness and efficacy by combining personalization and adaptivity based on an application-specific set of properties (the context) that may affect the execution of the application.

In this chapter, we focus on the development of context-aware applications for the Web and, in particular, we describe a *model-driven* development method that allows developers to approach the problem at a level of abstraction that enables him/her to focus on the real design challenges of such class of applications, leaving low-level implementation concerns to supporting CASE (Computer-Aided Software Engineering) tools. Considering that software systems are continuously getting more complex and difficult to maintain – partly due to the previously described requirements –, we believe that efficient abstraction mechanisms and design processes, such as those provided by visual, model-driven design methods, are becoming crucial. The focus on essential design issues and the ease of reuse in model-driven design methods may significantly accelerate the overall design process. As we will show in this chapter, starting from application models, code generation techniques may then provide for the automatic generation of application code or templates, thus assuring the fast production of consistent and high quality implementations.

MOTIVATING EXAMPLES

Active application features, such as context-aware or adaptive behaviors, may augment the effectiveness of interactions and the efficiency of resource consumption in all those situations where services and contents offered by an application strongly depend on environmental situations, users' abilities or disabilities, or the state or health of a software system. For example, typical applications demanding for active features and adaptivity are:

- *Adaptive personalization*. User profile attributes for personalization purposes may present different levels of variability in time. Profile properties may be static in nature (e.g. the name of a user), slowly changing (e.g. profile data derived from a user's browsing behavior) or even fast changing (e.g. the pulse frequency of a patient). Adaptive personalization mechanisms that take into account such profile peculiarities could allow systems to go beyond the common and static tailoring or services and contents.
- *Interaction-enabling functionalities*. Context could as well consider handicaps or physical disabilities of users, such as vision problems, blindness or paralysis, to adapt the application accordingly and to provide alternative and better suited interaction mechanisms and modalities. Adaptivity could thus provide functionalities enabling handicapped users to properly interact with applications, thus fostering the accessibility of applications.
- *Effective content delivery*. In general, whatever context data may be leveraged to provide appropriate contents and program features at the right time, priority, and emphasis. For example, specifically targeted special offers could be advertised and directed more effectively, presentation properties could be adapted to varying luminosity conditions for better readability, etc. Adaptive or context-aware extensions could thus enhance the overall effectiveness of applications by adapting individual application elements to varying users or usages of the application.
- *Delivery of context as content*. Applications may depend intrinsically and in a structural manner from context data. Location-aware applications, such as city map services or navigation systems, treat position data as core contents of the application and adapt to them, supported by proper localization mechanisms. To such kind of applications, the use of context data represents a functional requirement, rather than an optional feature.
- *Exception handling*. Critical events during the execution of a software system may raise exceptions and require prompt reactions being performed. Process-based or workflow-driven applications, for example, represent a typical class of applications that constantly have to cope with exceptional situations in order to guarantee the consistent termination of a running process. Here, adaptive or context-aware mechanisms could be leveraged to capture respective application events and to enact the pieces of application logic that are necessary to handle the exceptional situation.
- *Production and control systems*. Critical production or control systems may require, for example, highly specific sensing and alerting mechanisms to prevent production losses or product quality degradations. Context-awareness could facilitate the timeliness of reactions and the efficient handling of dangerous situations, but also proactive maintenance approaches, such as those adopted in a steadily growing number of hardware/software systems, may be achieved.
- *Self-healing software systems*. Autonomic or self-healing software systems elevate the idea of proactive maintenance from hardware to software systems and aim at the creation of computing systems that are able to configure, tune, and even repair themselves. Proactive and adaptive capabilities in this context are an essential feature.

REFERENCE SCENARIO

To exemplify the concepts introduced in this chapter and to better convey the underlying ideas, step by step we will show how we developed one of our demonstration prototypes, the PoliTour application. The application runs on a PDA with wireless Internet access and enables visitors to Politecnico di Milano, Italy, to obtain location-aware campus details (i.e. information about roads and buildings) while walking through the campus. If a user is about to leave the WiFi-covered area of the campus, an alert message is shown.

CONTEXT-AWARENESS AND WEB APPLICATIONS

Due to a lack of appropriate technologies and concepts, for a long time context-awareness has not been considered suited to the domain of the Web. Web technologies (both hardware and software) are however continuously evolving and the attitude toward reactive and context-aware behaviors in Web applications is changing. As a matter of fact, support for a multitude of non-functional requirements, whose inadequate coverage prevented the adoption of Web technologies for the implementation of reactive applications, has now been developed. Just to mention a few:

- The *reliability* of data communications has been considerably enhanced along both the software and the hardware dimension. The introduction of reliable messaging techniques (e.g. digital certificates or the WS-Reliability specification) provides for trustworthy communications on top of standard Web protocols, such as HTTP or SOAP. The success of fiber optics – as an example of hardware evolution – has allowed the Ethernet protocol (typically used in the Web) even to enter industrial production environments, where the high electromagnetic interferences that exist in the presence of high-voltage machineries practically prohibited the use of conventional, unreliable network technologies.
- The *pervasiveness* and *availability* of Web applications is continuously growing due to the introduction of novel networking technologies, such as ADSL (Asynchronous Digital Subscriber Line) or fiber optics for home and office users and WiFi and 3rd generation mobile telephony technologies (e.g. UMTS, GPRS, EDGE) for mobile users.
- Web applications have proved a high *scalability* (it suffices to think about certain portal applications that serve millions of users every day), facilitated *maintainability* and high *cost efficiency*.

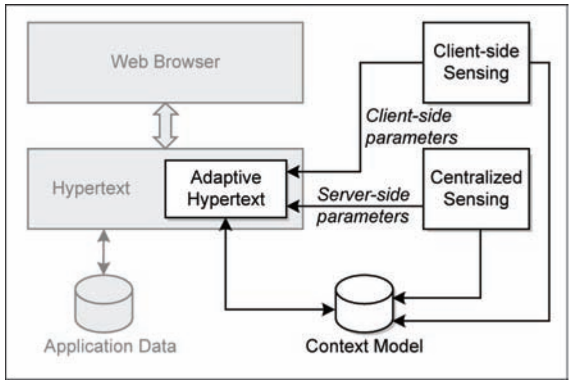
Provided that technological advances enable and facilitate the development of adaptive Web applications, it is important to recognize that context-awareness, rather than being a mere technological concern, represents a true *design* issue. In the following, we will thus focus on the typical design concerns in the development of context-aware Web applications.

Enabling Context-Awareness in the Web

Developing context-aware applications for the Web demands some characteristic architectural components, in order to support adaptations to context. Figure 1 proposes a possible functional architecture that extends the traditional architecture of Web applications with components aimed at supporting the acquisition, storage, and use of context data.

The typical context-aware application's data source includes both the application data (i.e. the business objects that characterize the application domain and the user) and the context model, which offers at any moment an up-to-date

Figure 1. Context data in context-aware Web applications. Gray shaded boxes correspond to conventional, non-adaptive parts, white boxes correspond to extensions required to support context-awareness



representation of the context state. The context model captures all the context-characterizing properties and enables the system to adapt to changes thereof, assuming that such changes may demand for proper reactions by the application. An application typically consists of adaptive (i.e. context-aware) and non-adaptive parts; we call the former adaptive hypertext. The pages of the adaptive hypertext present some form of adaptive behavior, i.e. they are able to react to changes in the context, while pages of the non-adaptive hypertext do not present any adaptive behavior. To decide which adaptation is required – if any –, the adaptive hypertext makes use of context data during the rendering of hypertext pages. Context data needs to be sensed (e.g. by means of suitable instruments, such as GPS positioning systems, thermometers, or similar) and communicated to the Web server that hosts the application, in order to be processed.

The above architecture allows for three main communication mechanisms to pass context data from the sensing devices to the application: (i) as parameters sensed at the *client side* and sent to the application (e.g. GPS position data); (ii) as *server-side* parameters (i.e. HTTP session variables) provided by a centralized sensing infrastructure (e.g. system usage data); and (iii) by means of direct updates of the *context model*. Typically, client-side parameters are generated by client-side sensing solutions, server-side parameters are filled by centralized sensing solutions, and database updates may be performed by both.

Context-awareness in Web applications therefore requires addressing the following issues:

- *Context data modeling.* Context properties that are relevant for the provisioning of the context-aware behaviors of the application must be identified and represented in an application-accessible format. The result of this task is the context model that can be queried for adaptation purposes.
- *Modeling of adaptive application behaviors*. Starting from the context model, adaptation operations need to be defined in order to react to situations demanding for adaptation. That is, detected changes to the context data are translated into visible effects or operations that aim at augmenting the effectiveness and usability of the application.
- *Context model management*. The context model only captures the static aspect of context data, i.e. their structure; in order to also capture the dynamics of context data, and hence to be able to trigger adaptive behaviors, we also need to:

  - *Acquire context data* by means of measures of real-world, physical properties, corresponding to the properties of the context model. The so acquired data are then fed into the context model, so as to keep the context model up to date.
  - *Monitor context data* to detect those variations in context data that trigger adaptivity. Relevant variations are used to enact the adaptation operations in the adaptive hypertext, thus causing an automatic, adaptive behavior of the Web application.

While the definition of the context model and the monitoring of context data can easily be assisted by proper context modeling methods and a proper runtime framework providing basic monitoring functions, it is not as easy to assist designers in the development of suitable context acquisition (i.e. sensing) infrastructures. In fact, the former two activities can be generalized beyond the needs of individual applications, while the design of sensing infrastructures remains tightly coupled with individual application requirements and technological choices. The exact development of sensing infrastructures is thus out of the scope of this chapter.

Context-Aware Behaviors in Web applications

But what exactly does it mean to adapt a Web application or to react to context? Starting from the work by Brusilovsky (1996) on adaptive hypermedia systems, in context-aware Web applications, adaptive behaviors may affect:

- *Contents and services* delivered by the accessed pages: the application may autonomously chose contents or services based on changing context data.
- The *navigation:* the application may perform automatic navigation actions on behalf of the user toward pages that better suit the current context conditions.
- The whole *hypertext structure:* the application may choose to apply coarse-grained adaptations (e.g. to the layout of the application), for example to react to changes of the user's device, role, or activity within a multi-channel, mobile environment.
- *Presentation properties*: the application may apply more fine-grained adjustments to the application's appearance (e.g. to style properties or fonts in use).
- *Generic operations*: the application may decide to enact generic operations in the background, e.g. to log specific application events or to interact with external applications.

In this chapter, we will describe how these behaviors have been realized in the model-driven design method WebML and how the resulting extended version of the method can be leveraged for the development of context-aware applications. Before proceeding with the discussion, it is thus appropriate to shortly introduce the WebML development method, which will serve as reference throughout this chapter.

The Web Modeling Language (WebML)

WebML is a visual language for specifying the content structure of Web applications and the organization and presentation of contents into one or more hypertexts (Ceri et al., 2002).

WebML application design starts with the specification of a *data schema*, expressing the organization of the application contents by means of well established data models, such as the Entity-Relationship model or the UML class diagram. On top of such data schema, WebML design then proceeds with the specification of a so-called *hypertext model*, which describes how contents, previously specified in the data schema, are published into the application hypertext. The overall structure of the hypertext is defined in terms of *site views*, *areas*, *pages*, and *content units*. A *site view* is a hypertext, designed to address a specific set of requirements. Several site views can be defined on top of the same data schema, for serving the needs of different user communities, or for arranging the composition of pages to meet the requirements of different access devices like PDAs, smart phones, and similar appliances. A site view is composed of *areas*, which are the main sections of the hypertext, and comprise recursively other sub-areas or pages. *Pages* are the actual containers of information delivered to the user; they are made of *content units*, which are the elementary pieces of information extracted from the data sources by means of queries, and published within pages. In particular, content units denote alternative ways for displaying one or more entity instances. Unit specification requires the definition of a *source* and a *selector*: the source is the name of the entity from which the unit's content is extracted; the selector is a condition, used for retrieving the actual objects of the source entity that contribute to the unit's content. Content units and pages are interconnected by *links* to constitute site views. Besides representing user navigation, links between units also specify the transportation of parameters that can be used by the destination unit in its selector condition. Some WebML units also support the specification of content management operations. Standard operations are creating, deleting or modifying an instance of an entity or adding or dropping a relationship between two instances; custom units may be defined. Finally, WebML also allows the management of *session parameters*; parameters can be set and consumed through proper units.

In addition to the visual representation, WebML also comes with an XML-based, textual representation, which allows one to specify additional detailed properties, not conveniently expressible in the graphic notation. The availability of the XML specification enables the automatic generation of the application code (Web Models, 2008), comprising rendering formats like HTML (which is the standard choice for deployment) or WML. For a detailed description of WebML, the interested reader is referred to (Ceri et al., 2002).

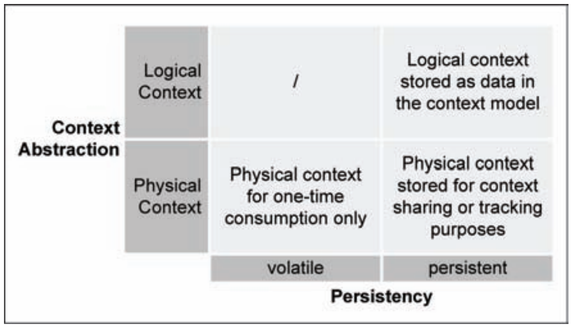
MODELING DATA FOR CONTEXT-AWARE WEB APPLICATIONS

Context data can derive from several sources integrating sensed, user-supplied, and derived information (Henricksen, 2004; Henricksen, 2002). While user-supplied data are generally reliable and tend to be static, sensed data are typically highly dynamic and can be unreliable due to noise or sensor errors. The problem of unreliability has been addressed in literature for example by associating context information with quality data (Lei, 2002). Although we recognize the importance of reliable context data, in this work we rather concentrate on the exploitation of context in the design of Web applications. For simplicity, throughout this chapter we thus consider sensed data as trustworthy.

Characterizing Context Data

The main goal of context modeling is the formalization and abstraction of the context properties that affect the application. In this regard, a first characteristic distinguishing context properties is the distinction between physical and logical context. We call *physical* context those properties that are immediate representations of sensed, physical quantities (e.g. the values of an analog/digital converter), and *logical* context those properties that enrich physical context with semantics and additional abstractions of the raw sensed data (e.g. the city corresponding to physical longitude and latitude values).

Figure 2. Persistence of physical and logical context data



A second characteristic affecting the structure of the context model is the *persistence* of context properties in the system, i.e. the property that expresses whether individual context properties represent persistent data or volatile data. *Persistent* data need to be stored in the application's data source and therefore require proper data entities being modeled as part of the context model, while *volatile* data do not need any storage and can thus be omitted from the context model. The context model therefore only captures persistent context data (indeed, in WebML the context-model is part of the database underlying the application).

Starting from these two characteristics and from the reference architecture introduced in Figure 1, Figure 2 summarizes the resulting characterization of context data:

- *Volatile physical context*. Context data communicated via client-side parameters or via server-side session parameters represent volatile data. They are immediately available during the execution of the application, independently of the underlying context model. Volatile context data are not enclosed in the context model; they might however be used during page computation to adapt the application.
- *Persistent physical context*. Context data sharing (e.g. between members of a same group) or tracking (e.g. to derive differential context properties or to keep a context history) typically require the persistent storage of data. Persistent physical context data are thus included in the context model and updated according to their dynamics.
- *Persistent logical context*. Logical context data is stored as data in the context model, so as to enable the data-driven transformation of physical context into logical context. Logical context data are typically static, as they provide abstractions of physical context; dynamic updates and/or extensions can, however, be supported as well.

Physical and logical context data therefore coexist in the application's data source. This coexistence typically requires a transformation or mapping between raw data and information that can directly be used when specifying hypertext schemas. Consistently with the data-driven approach that characterizes WebML, we propose a formalization of such transformation at the data level by means of suitable associations between data entities representing physical and logical context data, respectively. Although technically legal, we do not expect the use of *volatile logical context*, as volatile context data typically represents sensed raw context data.

It is worth noting that even though there are several properties commonly regarded as *context attributes* (e.g. position, time, or device characteristics), there exists no universal context model that applies to all kinds of applications. For this reason, also in this chapter we do not prescribe any precise, rigid context model for WebML applications; we rather introduce some WebML-specific modeling guidelines that enable the designer to provide context-aware applications with suitable context meta-data.

Example Data Schema for Adaptation in WebML

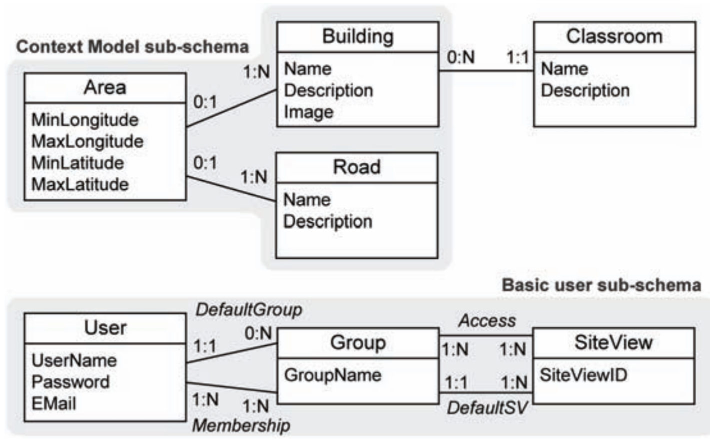
Let's consider the PoliTour application shortly discussed in the introduction. Figure 3 illustrates a possible Entity-Relationship diagram with basic user profile data and context data, grouped in the figure into so-called sub-schemas:

- *User profile sub-schema*. Users, groups, and site views are represented as "first-class citizens" in the application data source, as required by the WebML design process. The entity User provides a basic profile of the application's users, the entity Group associates access rights to users (i.e. a role), and the entity Site View contains the site views that may be accessed by the members of a group. The relationship Membership expresses that users may belong to multiple groups, which in turn cluster multiple users. The relationship DefaultGroup connects a user to his/her default role and, when logging into the application, the relationship DefaultSV allows the application to forward the user to his/her default group's default site view. The relationship Access expresses which site views a specific group is allowed to access; this relationship is required as varying context conditions may require different interaction and navigation structures for a same group. In this way, depending on the context state, the application is able to determine the most appropriate site view and to forward the user accordingly.
- *Context model sub-schema*. The context model of the application is represented by the entities Area, Building, and Road, which all provide logical context data. The actual GPS position data used for delivering the location-aware guide through the Politecnico campus (i.e. longitude and latitude) and the signal strength of the WiFi connection are not part of the context model in the application's data source; in developing the PoliTour application, we will handle such as volatile context data. Starting from the physically sensed data, the entity Area allows the application to identify a geographical area inside the campus; an area is then associated either with a Building or a Road, meaning that starting from the user's position we can identify whether he/she is located close to a building or rather walking through one of the roads in the campus.
- *Application data*. The remaining entity Classroom represents application data that are not part of the context model. This means that from a building it is possible to access the list of classrooms of the building, but there are no adaptive behaviors associated with the entity Classroom.

MODELING CONTEXT-AWARE HYPERTEXTS

While the first step of the WebML design method, i.e. data modeling, does not require any extension of the modeling primitives for capturing context data (the standard Entity-Relationship primitives suffice), WebML hypertext modeling does require a few model extensions to express adaptivity concerns. Next we therefore introduce the new concepts and primitives that have been developed to express adaptive behaviors, and we clarify how different adaptivity policies can be used to enact adaptations.

Figure 3. Adaptation-triggering data in WebML applications, partitioned into basic user sub-schema, personalization sub-schema and context sub-schema

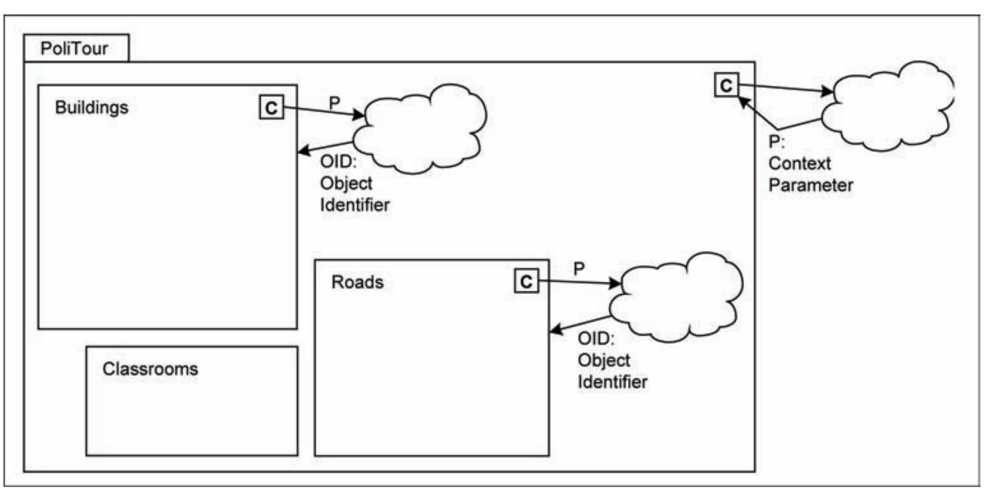


Context-Aware Pages and Containers

Our basic assumption in the modeling of context-aware hypertexts is that context-awareness or adaptivity is a property to be associated only to some *pages* of an application (the *adaptive hypertext*), not necessarily to the application as a whole. Location-aware applications, for example, adapt core contents to the position of a user, and so-called "access pages" (e.g. containing categories or lists) typically are not affected by the context of use.

As can be seen in Figure 4, we tag context-aware pages with a C-label (standing for *context-aware*) to distinguish them from conventional pages. The label indicates that an adaptivity rule (stylized as a cloud) is associated with the page and that during the execution of the application this logic must be taken into account when com-

Figure 4. WebML hypertext schema with one context-aware site view and two context-aware pages. The parameter P exemplifies the propagation of reusable context data by hierarchically passing context parameters from an outer area to an inner page



puting the page. Specifically, Figure 4 states that pages Buildings and Roads are context-aware, while the page Classrooms does not present any adaptive behavior.

There might also be the need for adaptivity rules with effects that spread over multiple pages. For this purpose, we exploit the hierarchical structure of hypertexts; that is, we allow the definition of context-aware *containers* (i.e. *site views* and *areas*, in terms of WebML). This allows the designer to insulate and to specify only once adaptivity rules that are common to multiple C-pages inside a container and thus to reduce the redundancy of the schema. Adaptivity rules associated to containers and pages are evaluated recursively, starting from the outermost container and ending with the actual pages. The site view PoliTour in Figure 4 is context-aware; we will see later on why.

Localized and Sparse Adaptivity Rules

The adaptivity rules attached to the context-aware pages and containers in Figure 4 represent the actual adaptivity logic (i.e. the set of adaptivity actions to be performed). The adaptivity logic is external to the page or container, and the chain of adaptivity actions it clusters is kept separate from the page or container specification. The aim is to highlight the two different logics deriving from the role played by pages/containers and adaptivity operations: while the former act as *providers* of contents and services, the latter act as *modifiers* of such contents and services.

Adaptivity actions attached to a C-page typically present effects that are visible in the page they are attached to. The notion of context-aware page and adaptation logic therefore defines what we call a *localized adaptivity rule*: the scope of a localized adaptivity rule is strictly coupled with a fixed set of hypertext pages, where "scope" refers to those (adaptive) pages to which the page's adaptivity actions are associated.

The notion of context-aware container allows us to define *sparse adaptivity rules*: we talk about *sparse* adaptivity rules in those cases, where adaptivity actions are associated to containers that contain multiple pages; the scope of such actions spans a set of pages, more precisely, all context-aware pages in the container. Coming back to the PoliTour application sketched in Figure 4, we can thus associate the logic to interpret the signal strength of the WiFi connection to the pages Buildings and Roads by applying the logic to the site view as a whole.

Parameter Passing

Adaptivity logic is associated to a page by means of a directed arrow, i.e. a link exiting the C-label. This link ensures the communication between the page logic and the adaptivity logic: it may transport parameters deriving from page contents, which may be used to compute the specified actions; in turn, a link from the adaptivity logic to the page may transport context parameters or generic values that might be required to perform the final adaptation during page computation.

But Figure 4 also illustrates the possibility of *hierarchically* passing parameters from an outer container to an inner one. More precisely, if the evaluation of outer adaptivity logic produces results to be reused at an inner level, as it might happen in the case of context parameters, it passes such values back to the C-label that activated the computation of the logic. Subsequently, such parameters can then be "consumed" by adaptivity logics of the inner levels. As for context-aware pages, parameter passing from a container to its adaptivity logic occurs through the logic-activating link. Links exiting the last evaluated logic, i.e. at the end of the last adaptivity action, might carry parameter values for the computation of units inside a page.

Typical actions to be specified at the container level are the acquisition of fresh context data and the updating of the context model, e.g. if the data are to be shared among multiple users or if a history of context data is to be tracked. Hence, especially if persistent context data are adopted, we propose two levels for adaptivity actions:

- *Actions for context model management*, addressing operations for context data acquisition and context model updating, should be associated with outer containers (site views or areas) and are inherited by inner containers (areas or pages). These adaptivity actions need to be executed prior to the execution of any other action possibly specified in an inner context cloud, as such "internal" actions could depend on context data acquired and stored in the context model through "external" actions.
- *Actions for hypertext adaptivity*, defining the rules for page and navigation adaptation (and possibly depending on persistent context data), should be associated with C-pages.

Specifying Adaptivity Logics

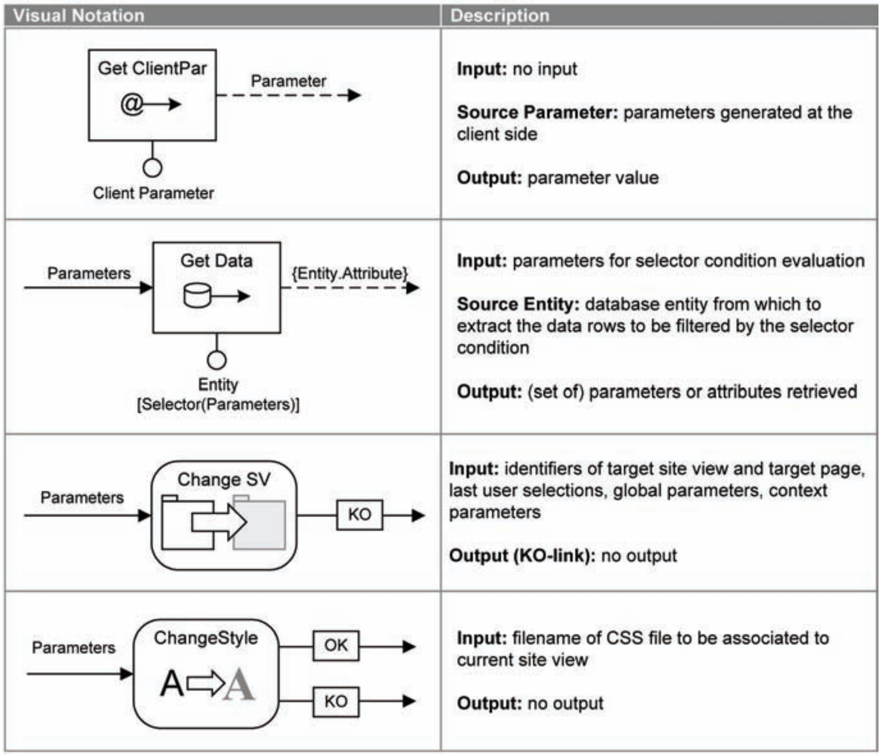
The main novelties for modeling context-aware pages reside in the specification of adaptivity rules by means of WebML constructs. In the following, we introduce the new WebML modeling concepts that ensure full coverage for the specification of context model management and hypertext adaptation logics. The new primitives allow designers to visually specify actions for acquiring and updating context data and to define adaptivity actions.

Managing Context Data

In order to support adaptivity with respect context, the application must be able to acquire and manage context data according to the mechanisms illustrated in Figure 1. For this purpose, some new WebML operations have been defined, which, together with the already available operations, provide the necessary primitives for:

- *Specifying the acquisition of fresh context data through client-side parameters*. A new Get ClientParameter unit (see Figure 5) has been defined to support the retrieval of parameters generated at the client side and communicated back to the application via client-side parameters (e.g. parameter-value pairs attached to the page request query string).
- *Specifying the acquisition of fresh context data through server-side parameters*. Context data directly made available as HTTP session parameters can be accessed by means of conventional WebML Get units (Ceri et al., 2002).
- *Specifying the acquisition of context data from the context model*. The execution of adaptivity actions may require the retrieval and evaluation of context meta-data, for example, in situations where certain data are just needed to evaluate condition expressions. For this purpose, a so-called Get Data unit (see Figure 5) has been introduced, enabling the retrieval of values (both scalars and sets) from the data source according to a selector condition. The semantics of the Get Data unit is similar to the one of content publishing units (Ceri et al., 2002), with the only difference that data retrieved from the data source are not published in hypertexts, but just used as input for units or operations.
- *Updating the context model*. Once fresh context parameters have been retrieved, they can be used to update the context model at data level. This action consists in modifying values previously stored in the data source. In WebML, this is already facilitated by operation units (Ceri et al., 2002) providing support for the most

Figure 5. WebML units that have been defined for the specification of adaptivity actions



common database management operations (e.g., modify, insert, delete).

Evaluating Conditions

The execution of adaptivity actions may be subject to the evaluation of some *conditions*, refining the triggering logic for context clouds. The most recurrent pattern consists in evaluating whether context changes demand for adaptation. The evaluation of conditions is specified by means of two control structures, represented by the If and Switch operation units, which have been introduced for workflow modeling in WebML (Brambilla et al., 2003).

Executing Adaptivity Actions

Once the current context state has been determined, and possible conditions have been evaluated, adaptivity actions can be performed to adapt the page contents, the navigation, the current site view structure, and/or presentation style properties. These actions are specified as follows:

- *Adapting Page Contents*. Page contents are adapted by means of proper data selectors, whose definition is based on context parameters retrieved from the context model or newly computed within the page's context logic. The use of parameterized selectors allows for both *filtering* data items with respect to the current context state and conditionally *including/excluding* (i.e. showing/hiding) individual content units.
- *Adapting Navigation*. In some cases, the effect of condition evaluation within the context cloud can be an automatic, i.e. context-triggered, navigation action, causing the redirection of the user to a different

page. The specification of context-triggered navigations just requires connecting one of the links exiting the adaptivity logic of the page to an arbitrary destination page of the hypertext. Therefore, links exiting the context cloud and directed to other pages than the adaptivity logic's source page represent automatic navigation actions.

- *Adapting the Site View*. In some cases, a context-triggered switch toward a different site view may be required. Changes in the interaction context may in fact ask for a coarse-grained restructuring of the whole hypertext, for example because the user device has changed, or because the user shifted to a different activity. To switch between different site views, we have introduced a Change Site View unit (see Figure 5), which takes in input the identifiers of the target site view and the target page, to be visualized in case a switch toward the specified site view is required. In order to support "contextual" switching, the input link also transports parameters characterizing the current state of interaction, i.e.:
    1. The input parameters of the source page, which represent the last selections operated by the user;
    2. Global parameters, representing session data (e.g. user identifier and group identifier), as well as past user selections that have been used for the computation of the current page;
    3. Client-side and server-side context parameters retrieved during the latest performed data acquisition cycle and characterizing the current context state.
- *Adapting Presentation Style*. Sometimes context changes may require only fine-grained adaptations of presentation properties (e.g. due to varying luminosity conditions), not a complete restructuring of the overall hypertext. We have defined a Change Style unit for dynamically assigning presentation style properties (see Figure 5). Style properties are collected in proper .css (Cascaded Style Sheet) files, and the unit enables the application to change its associated style sheet at runtime.
- *Enacting generic operations*. The context-triggered invocation of generic operations or, for instance, external Web services can easily be specified by placing the respective WebML operation unit into the page's adaptivity logic and by providing the unit with the necessary input parameters.

Triggering Adaptivity Rules

But *when* do we enact an adaptivity rule? In this regard, it is possible to define two different *adaptivity policies* for context-aware pages, assigning different priorities to users and context:

- *Deferred Adaptivity*: the *user* is granted the highest priority. Therefore, after the user has entered the page and the page has been rendered according to the user's selections, the page's adaptivity logic is evaluated at periodic time intervals, enabling the application to possibly adapt the already rendered page. Periodically evaluating the adaptivity logic means periodically refreshing the page visualized in the browser.
- *Immediate Adaptivity*: *context* is granted the highest priority. The page's adaptivity logic is evaluated each time the page is accessed, being the access due to the user or to the periodic refresh of the page. This means that the page is subject to adaptation each time it is rendered, even at the first time the page is accessed by the user.

Consider for example our PoliTour guide that shows contents about the buildings and roads in the Politecnico campus. At a given point, the user might want to get information about a specific building located in a road that is not related to his/her current position; such a preference is typically expressed by selecting a link to that building from a list. With a deferred policy, the requested page shows the building information as requested by the user, without taking into account the user's current location. Only after expiration of the refresh interval, the page becomes subject to adaptivity and the contents are adapted to the user's location. With an immediate policy, context is granted higher priority with respect to the user and, thus, the user's request for the building would be overwritten by the context and the application would show the building or road associated to the user's current location, discarding the user's selection.

Note that in addition to these adaptivity policies, we recognize that there may be situations that demand for an explicit control of the adaptation dynamics through the user. Therefore, should for example a user temporarily not be interested in having the contents adapted to his/her location, he/she can simply disable/enable adaptivity at will. In WebML, the adaptivity policy for context-aware pages and containers is declared by means of the Adaptivity_Policy property of context-aware pages and containers.

Adaptivity policies can also be associated to context-aware containers. When a C-page is requested, also the possible context clouds of its containers are evaluated recursively (from the outermost one to the innermost one), according to the adaptivity policy associated to each container. In general, a container's adaptivity policy is independent of the policy of inner containers and pages (if not, this must be taken into account by designers when associating policies to containers and pages). Therefore, it may happen that the actions in a container's context cloud are evaluated immediately, even if the actions associated to inner containers or pages adopt a deferred evaluation, or vice-versa. If, for example, the adaptivity actions associated to the container serve for tracking a context history, they could require an immediate policy, while inner adaptivity actions keep their deferred policy for front-end adaptations. The hierarchical definition of context clouds may therefore also be considered a facility to achieve different "layers" of adaptivity actions.

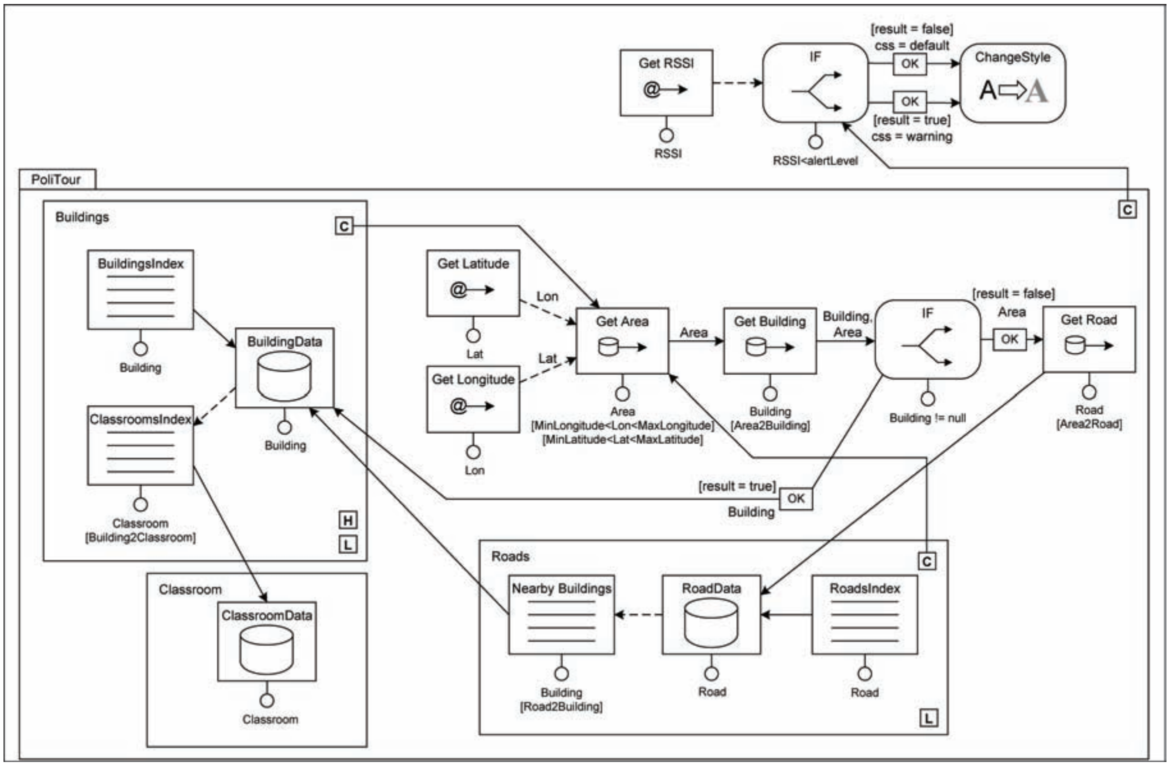
In our approach, we assume *deferred* adaptivity as default policy. This choice aims at minimizing application behaviors that might be perceived as invasive or annoying by users and has been experienced as the most natural for modeling adaptation. However, the *immediate* policy could be needed for handling exceptional situations, as in such cases the timely reaction to context changes could be more important than following the user's indications. We therefore, in general, recommend the selection of the adaptivity policy that is appropriate to the application requirements and that is able to minimize the application behaviors that could be perceived as invasive or annoying by the users. In order to choose the right adaptivity policy for an adaptive page, a developer therefore needs to predict what kind of adaptive behavior a user will expect when accessing that page.

Example Hypertext Model

Figure 6 shows the adaptive WebML hypertext model of the PoliTour application. The figure provides a refinement of the coarse hypertext model introduced in Figure 4 and details the internals of pages and adaptivity logics.

The pages Buildings and Roads share the same adaptivity logic providing location-awareness to the displayed contents. The logic starts with two Get ClientParameter units accessing the user's longitude and latitude, which are then used by the Get Area unit to associate a logical area to the user's position. A further Get Data unit (the Get Building unit) then tries to retrieve a building for the identified area. If a building could be retrieved, the If unit sends the user to the Buildings page, providing updated page parameters. If instead no building could be retrieved (e.g. because the user is located in the center of a road or not close

Figure 6. Hypertext model of the PoliTour application leveraging volatile context data



enough to a building), the If unit forwards the Area identifier to the Get Road unit, which retrieves the road associated to the current position.

Therefore, if the user views the page Buildings while walking around the campus, the application automatically updates the contents published each time a new building can be found. If only the road can be identified, the application performs an automatic navigation action toward the Roads page, where the described adaptive behavior starts again, possibly causing the adaptation of contents or automatic navigation actions. Only if the user navigates to page Classroom, no adaptations are performed, as this page is not tagged as context-aware.

The adaptivity actions associated to the surrounding site view specify how to alert users who are about to leave the WiFi-covered area. The Get RSSI unit accesses the volatile RSSI parameter sensed at the client side, and the If unit compares the retrieved value with a predefined level (alertLevel), below of which the connectivity is considered low. In case of low connectivity, the style sheet warning is adopted; otherwise, the default style sheet is adopted. We therefore model the alert of low connectivity conditions by means of a Change Style unit: under low connectivity conditions the application is rendered with a red background, under normal conditions the application is rendered with a gray background.

We recall that actions associated to containers are evaluated before any action at the page level is started. Hence, in Figure 6 the actions associated to the site view are executed before the actions associated to the pages Buildings and Roads.

RUNTIME CONTEXT MODEL MANAGEMENT

In order to manifest context-aware behaviors, the application must be equipped with the capability to monitor the context state and to trigger adaptivity actions, if required. The standard HTTP protocol underlying most of today's Web applications implements a strict *pull* paradigm, in which computations can only occur in response to client-side generated page requests. Therefore, in the classical Web architecture, lacking proper push mechanisms, context monitoring can occur only when a page is computed, i.e. when a respective page request reaches the Web server. Three main solutions can be adopted to trigger the evaluation of adaptivity rules: (i) context evaluation on user-generated page requests, (ii) periodical, automatic refreshes of viewed pages to enable context evaluation, and (iii) active context evaluation to trigger adaptivity in real time. The first solution is not able to cope with the dynamic nature of context. The periodic refresh of context-aware pages provides a way to ensure the update of the page even in absence of explicit user actions enabling the re-computation of the page. In the following, we will show an active mechanism for triggering adaptivity, which operates independently of the user in the background and comes close to the real-time triggering solution.

In absence of dedicated server-side *push* mechanisms for delivering updated pages, the HTML http-equiv META-option or JavaScript, JavaApplets, and Flash scripts, provide valuable client-side mechanisms to approximate the required active behavior. The approximation is based on periodic HTTP requests toward the application server, which are operated in the background and may serve a twofold purpose:

- On the one hand, they provide the necessary polling mechanism to query the context model and trigger the adaptivity rule attached to the page.
- On the other hand, generating page requests allows the client to transmit client-side sensed data, thus enabling the communication of context data to the application server.

Context-aware pages are therefore also characterized by an individual *refresh interval*, which can be specified as property (Refresh_Interval) of the page in the XML representation of the WebML model. Differently from C-pages, a container does not require the specification of any polling interval, which is instead derived from the interval associated to the currently viewed C-page of the container.

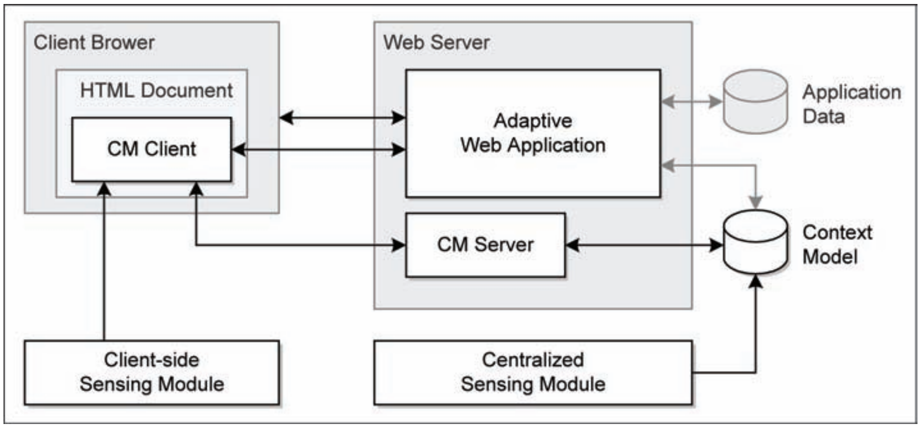
Context Monitoring

Context monitoring in the background (i.e. without the user observing any unwanted rendering activity) enables the application to limit the use of the refresh to those situations that really ask for adaptation and to perform context monitoring without any visual effect for users.

Figure 7 shows a functional architecture for adaptive Web applications that extends the described architecture of WebML applications (see Figure 1) with a new client-server module, called *Context Monitor* (CM), providing the necessary context monitoring logic. As further depicted by the figure, in case of client-side context sensing, the CM module also enables the communication of client-side sensed context parameters, which could be required at the server side to evaluate context changes and/or conditions over context parameters.

The CM consists of two separate modules, one on the client side and one on the server side. The CM Client module is a piece of business logic embedded into the page's HTML code and executed at the client side (e.g. a JavaScript function, a Java applet, or a Flash object), while the CM Server module works in parallel to the Web application on the same Web server. The CM

Figure 7. Functional architecture for background context monitoring



Client is in charge of periodically monitoring the context state and deciding whether possibly occurring context variations demand for the adaptation of the currently viewed page.

In order to be able to take a decision about whether adaptivity actions are to be triggered or not, the CM Client is assisted by the CM Server, which has full access to the context model of the application maintained at the server side. In response to the polling executed by the CM Client, the CM Server queries the context model and provides the CM Client with an updated picture of the effective context state. By comparing the state of the (server-side) context model acquired by the current polling with the one acquired by the last polling (or the state at page computation time), the CM Client knows whether the state has changed. If the state has changed, the CM Client asks the Web application for a refresh of the currently viewed page, i.e. the adaptation; if the state has not changed the CM Client proceeds with the monitoring of the context state.

Page Context

In general, the *state* of the context is expressed by the values of all the persistent parameters stored in the context model and of the volatile parameters sensed at the client or server side. However, an individual page's adaptive behavior is typically influenced by only a subset of the overall context data or, more specifically, by a function expressed over context data. The subset of context data corresponds to a page-specific view over the application's context data, narrowing the focus of the context monitoring activity. This observation leads to the definition of a new concept, i.e. page context, which can be leveraged to enhance the efficiency of the context monitoring activity: the *page context* of a page corresponds to a page-specific view over the application's context data, capturing all (and only) those context characteristics that effectively determine the adaptive behavior of the page.

Instead of monitoring the whole state of the application's context data, the definition of a page context for each adaptive page enables the context monitoring activity to focus its observation of the context state to the only page context. This implies, that during hypertext specification each adaptivity rule can be related to a subset of context parameters to be controlled, so that rule conditions do not need to check the state of the whole context model.

Page Context Parameters

In line with the idea of page context, the CM focuses its attention only to the subset of context data in the context model that really determines the adaptive behavior of the viewed page. This implies explicit knowledge of the pages' page context, which can be achieved by defining proper page context parameters for each context-aware page: p*age context parameters* define the view over the context model that captures all the static and dynamic properties of a page's page context by means of suitable queries over the context model.

This definition implies that each change to a page context parameter effectively corresponds to a need to adapt the page. The granularity of the *values* of page context parameters must thus be chosen in a way that each change of a parameter value translates into the triggering of the page's adaptivity rule. Each C-labeled page in the adaptive hypertext model is thus associated with an individual page context by means of proper page context parameters stored in the textual representation of the WebML schema, as they are not conveniently expressible in a visual manner. Page context parameters are expressed by means of parametric queries over the context data, where the parameters correspond to client- or server-side context parameters.

Context Digest

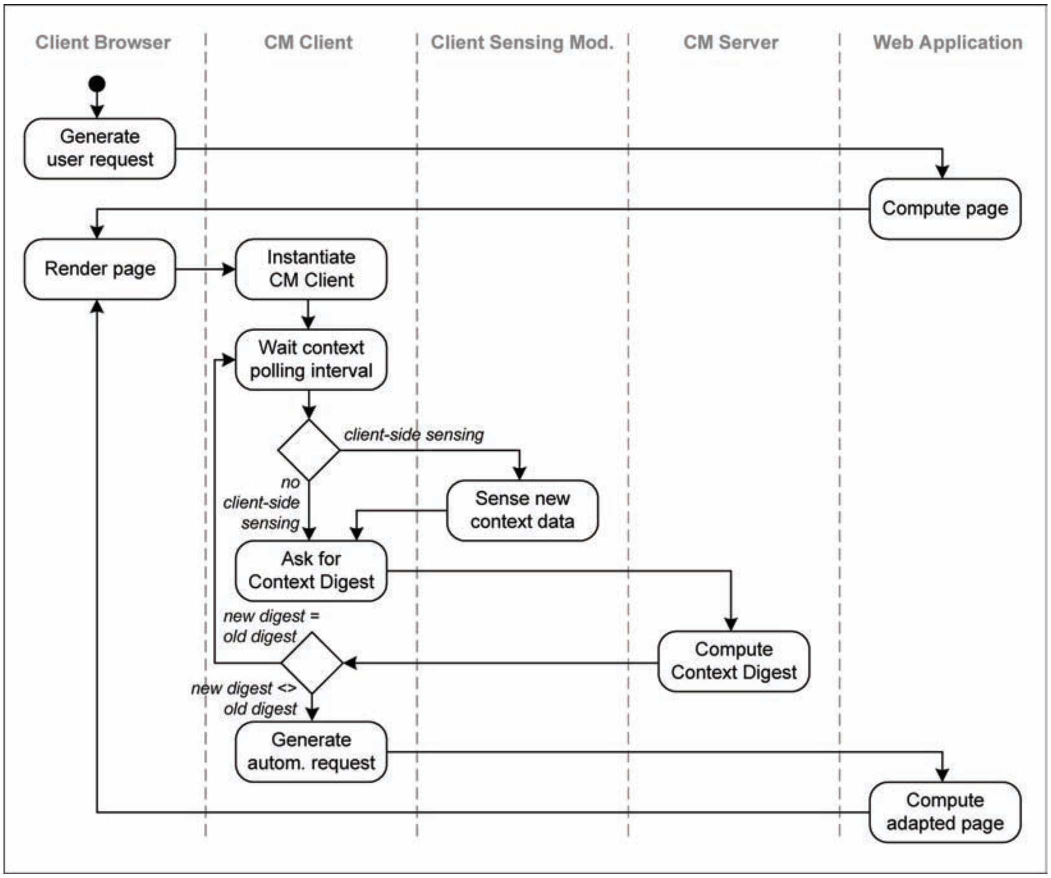
In order for the CM to be able to decide whether adaptivity is required, changes to the page context (i.e. the page context parameters) must be communicated from the CM Server to the CM Client. In order to enhance the efficiency of the overall context monitoring activity, the state of the page context is not communicated from the CM Server to the CM Client in form of the set of page context parameters, but instead it suffices to transmit and compare a numeric digest computed over the respective page context parameters, as each change to the values of the page context parameters also results in a change of the numeric digest. We call such a numeric digest context digest: the *context digest* corresponding to the page context of a page is the numeric checksum computed over the ordered list of page context parameters.

The context digest is the basis for the decisions to be taken by the CM Client: its values identify variations in the page context, which correspond to the need to adapt the page. The decision is based on the comparison of the current context digest with the last context digest; the first context digest, i.e. when the user accesses the page, is initialized with the context digest valid during page computation.

Figure 8 details the resulting flow of activities enabling the active behavior of the application and shows how the single modules cooperate in order to determine whether adaptivity is required or not. The diagram has one start node (Generate user request), which corresponds to the user's navigation to a C-page, and no end node, since the cycle in the lower part of the diagram is only interrupted by an explicit user navigation leading the user to another C-page (which corresponds to starting again from the start node of the diagram and monitoring the Page context of the new page) or to a conventional page (which does not cause any context monitoring activity).

Note that the described mechanism assumes that connectivity is available during the viewing of a C-page in order for the CM client to be able to communicate with the CM server. In case of intermittent connectivity, which is a very frequent situation in mobile environments, the CM client keeps working by periodically polling the CM Server, despite the absence of connectivity. The CM Client is however programmed to manage possible lacks of connectivity and therefore does not generate errors, with the only side effect that adaptivity is suspended until the connectivity is restored.

Figure 8. Background context monitoring for active context-awareness (with client-side context sensing): communicating context data and triggering adaptivity

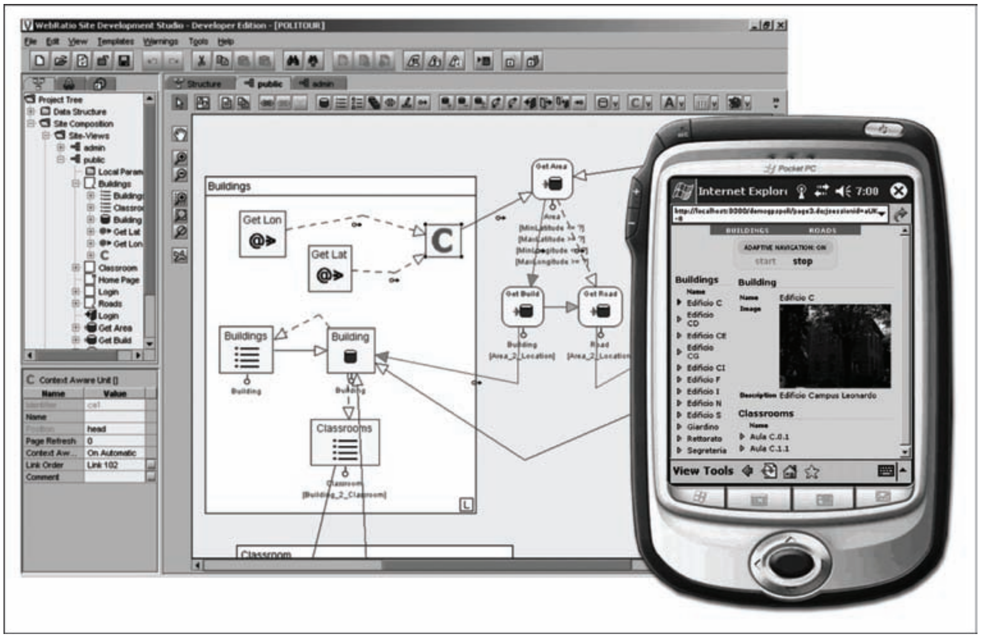


APPLICATION IMPLEMENTATION

The extensions that have been introduced into the WebML development method to cope with the new requirements posed by context-awareness and adaptivity in Web applications have been implemented as prototype extension of the WebRatio CASE tool, the official WebML modeling tool, equipped with a powerful automatic code generator. Due to implementation restrictions imposed by the modeling tool, the implementation of the adaptivity logic slightly differs from the models described in this paper (e.g. it was not possible to implement context-aware containers or to place all the adaptivity operations outside pages). Nevertheless, the described expressive power for the specification of adaptivity rules could be preserved.

Figure 9 shows a screenshot of the WebRatio tool at work. The figure shows the WebML hypertext model of the Buildings page of the PoliTour application, along with its adaptivity logic: two Get ClientParameter units access the GPS coordinates and pass them to the C-label, which forwards them to the outer adaptivity logic (cf. Figure 6). Starting from the shown hypertext model, the PoliTour application has been automatically generated on top of a J2EE platform. The configuration of the Context Monitor has been performed manually. To access GPS position data, we leverage a client-side Bluetooth GPS device, interfaced via the Chaeron GPS Library (http://www.chaeron.

Figure 9. The WebRatio CASE tool showing the hypertext model of the buildings page with respective adaptivity actions and the generated PoliTour application running on a PDA



com/gps.html) and wrapped by means of Flash (to exchange position data between the CM Client and the GPS library). The WiFi RSSI indicator is acquired in the PDA using Place Lab (http://www.placelab.org).

RELATED WORKS

Several other well-established, conceptual design methods have been so far extended to deal with Web application adaptations. Frasincar & Houben (2002), for example, extend the Hera methodology with two kinds of adaptation: adaptability with respect to the user device and adaptivity based on user profile data. Adaptation rules (and the Hera schemas) are expressed in RDF(S) (Resource Description Framework/RDF Schema), attached to slices and executed by the AHA engine (De Bra et al., 2003). The UWA Consortium proposes WUML (Kappel et al., 2001) for conceptual hypertext design. Adaptation requirements are expressed by means of OCL-based customization rules, referring to UML class or package elements. Casteleyn et al. (2003) present an extension of WSDM (De Troyer & Leune, 1998) to cover the specification of adaptive behaviors. In particular, an event-based Adaptive Specification Language (ASL) is defined, which allows designers to express adaptations on the structure and the navigation of the Web site. Such adaptations consist in transformations of the navigation model that can be applied to nodes (deleting/adding nodes), information chunks (connecting/disconnecting chunks to/from a node), and links (adding/deleting links). Baumeister et al. (2005) explore Aspect-Oriented Programming techniques to model adaptivity in the context of the UML-based Web engineering method UWE. Recently, WebML (Ceri et al., 2002) has been extended to cover adaptivity and context-awareness (Ceri et al., 2007). New visual primitives cover the specification of adaptivity rules to evaluate conditions and to trigger some actions for adapting page contents, navigation, hypertext structure, and presentation. Also, the data model has been enriched to represent metadata supporting adaptivity.

Recently, active rules, based on the ECA (Event-Condition-Action) paradigm, have been proposed as a way to solve the previous problem. Initially exploited especially in fields such as content evolution and reactive Web (Alferes et al., 2005; Bailey et al., 2002; Bonifati et al., 2002), ECA rules have been adopted to support adaptivity in Web applications. In particular, the specification of decoupled adaptivity rules provides a way to design adaptive behaviors along an orthogonal dimension. Among the most recent and notable proposals, the work described in (Garrigos et al., 2005a) enriches the OO-H model with personalization rules for profile groups: rules are defined in PRML (Personalization Rule Modeling Language) and are attached to links in the OO-H Navigation Access Diagram. The use of a PRML rule engine is envisioned in (Garrigos et al., 2005b), but its real potential for adaptivity management also at runtime remains unexplored.

The previous works benefit from the adoption of conceptual models, which provide designers with powerful means to reason at a high-level of abstraction, independently of implementation details. There are however also co-called transcoding solutions, which adopt active rules for adapting Web pages. Most of them focus on the presentation layer and provide mechanisms to transform HTML pages according to (possibly limited) device capabilities (Hori et al., 2000) or users' visual disabilities (Yesilada et al., 2004). Moreover, they typically support only adaptability and modify Web pages in relation to a static set of user or device parameters. Fiala and Houben (2005) adopt the transcoding paradigm for the development of the Generic Adaptation Component (GAC). GAC provides a broad range of adaptation behaviors, especially supporting run time adaptivity. An RDF-based rule language is used for specifying both content adaptation and context data update rules. A collection of operations implementing these rules is provided. A notable feature, promoting portability, is that GAC can be integrated as a stand-alone module into any Web site architecture.

CONCLUSION AND FUTURE TRENDS

In this chapter, we have proposed a model-driven approach to the development of context-aware Web applications, an increasingly relevant kind of applications on the Web. We have shown that context-awareness is a first-class design concern that can considerably be aided by model-driven development techniques. But we have also shown that properly dealing with context-awareness and adaptivity at the conceptual level requires extending the expressive power of the adopted conceptual application model, so as to provide developers with suitable modeling constructs and implementation abstractions, proper of such new class of application features. In this chapter, such extensions have been introduced into the already well-established WebML modeling language, but in a similar way we could have also opted for another modeling language, as the ideas and concepts introduced in this chapter are general enough in nature to be applied to other conceptual models as well.

For the future, we believe that a *decoupled runtime management* of adaptivity features will represent a next step in the area of adaptive Web applications. The development of Web applications is more and more based on fast and incremental deployments with multiple development cycles. The same consideration also holds for context-aware and adaptive Web applications and their adaptivity requirements. In (Daniel et al., 2008) we describe our first results obtained with a decoupled environment for the execution and the administration of adaptivity rules. The described approach allows us to abstract adaptive behaviors, to extract them from the main application logic, and to provide a decoupled management support, finally enhancing the maintainability and evolvability of the overall application.

In line with the current hype of so-called Web 2.0 applications, we are also working on the *mash-up* of context-aware Web applications, in the context of our component-based development method for Web applications called Mixup (Yu et al., 2007). The final goal of the work is to enable even end users to mash up their own context-aware applications, starting from a set of so-called context components and other components equipped with own user interface (which is used to build up the user interface of the mash-up application). Mash-up development is assisted by an easy-to-use and intuitive graphical development environment that supports a drag-and-drop development and by a light-weight runtime environment that is able to interpret and run the mashup, both fully running in the client browser and based on AJAX technology.

Chapter 2.11

Different Web Strategies for Different E-Marketplaces

L. Geppert
Catholic University of Milan, Italy

ABSTRACT

This chapter presents two possible models of electronic marketplaces put in place at the beginning of this century, which, after their introduction, the first incoming wave of connected economy-based paradigms was ended. Both the two models show a particular use of Web-based information technology in order to exploit their mission and represent meaningful cases of application of well-defined Web strategies. Even though, at the moment, the initially built Web sites supporting those related business have been closed and merged with other Web sites, they may introduce examples of a Web strategy approach having a relevant historical meaning that may be still redefined in practical implementations once revised and adequately updated. The mentioned cases described in this chapter are usteel.com and up2gold.com, two examples of Web-based business in two well-defined supply chains, that is, the "steel" chain and the "gold and silver" chain.

DOI: 10.4018/978-1-60566-024-0.ch006

INTRODUCTION

After the first incoming wave of the connected economy ended, investors, business managers, consultants, and specialists began to review their plans, actions, and methodologies. Many e-business models, both business-to-business (B2B) and business-to-consumer (B2C), are currently under consideration in order to assess and verify their real effectiveness (Kalakota & Whinston, 1996). The models applied so far have generally shown that, with some exceptions related to e-procurement implementations of large enterprises (Timmers, 1999), vertical marketplaces owners must look for different business paradigms in order to economically survive and to be actually able to create value to market industries chains they address (McDonald, 1997). In the following pages, two real cases are described: one trading marketplace addressing the steel industry as an example of “first wave” e-marketplace and one supply chain-like Web portal built for the Arezzo’s (Italy) gold manufacturing supply chain. The first case relates to a “traditional Web strategy”-based e-marketplace with a standard approach and contents (Shapiro & Varian, 1998) and the second shows an innovative strategy and a new business model (Porter, 1985). Even though, at the moment, both of the abovementioned e-marketplaces have merged their activities and brands in other larger e-commerce initiatives, at the time they were presented (2001), they represented important and innovative examples of an e-marketplace-based business model.

BACKGROUND

As some analyst observes, “the first high-visibility Internet businesses conceived to attract significant investor attention were, at the beginning, in the business-to-consumer (B2C) relationships, providing facilities for consumers to choose and purchase goods online. It seemed logical to think, as a related consequence, a development also of B2B, based on the “buying and selling” part of the relationship between businesses.

Thus, starting in 1999, and accelerating rapidly through 2000, the focus of B2B attention was very firmly on those initiatives that seemed to be capable of exploiting information and communication technology to alter the balance of power in trading relationships. These initiatives, which covered a wide spectrum of business and technical services, gained the general title of “marketplaces,” and, throughout 2000, the focus of B2B activities was on developing marketplace interaction strategies and examining procurement processes.

The focus on the transactional elements of B2B relationships will come to be seen as

an aberrant commencement to the development of the connected economy that will emerge in the 21st century. Businesses interact with other businesses in hundreds of ways. It is true that the interactions are generally intended to result in a commercial transaction. However, for many business relationships, the crucial performance-enhancing interactions take place before and after the transactions, and B2B will expand to occupy these broader horizons. (Kyte, 2001)

Business managers’ and investors’ expectations were very high at the end of the last century. They understood the strategic importance of B2B electronic model in particular and invested their money and their commitment, demanding rapid deployment of innovative business systems, which the IT community was increasingly hard-pressed to deliver. Many of these systems were new breed of applications, designed to change the external relations in the B2B world.

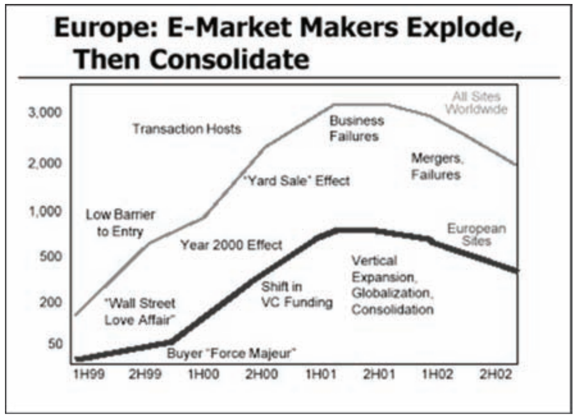
These systems work fine on the drawing board. However, actually developing externally focused applications as robust, reliable, secure systems with high availability and very high adaptability was and still currently is a challenge that only few IT specialists know how to address.

Furthermore, models of marketplaces so far implemented put the stress and focus of their business model on the transactional aspect. This model, which can act and succeed—or, better, survive—in all those case where the liquidity is reached in a sensible spell of time, does not take into account a natural evolution of electronic ecosystems where the complexity of relationships is becoming more and more vital.

However, the connected economy and B2B marketplace models with it have just started their evolution and growth, which will not be stopped; they just need some adaptation mechanism to consolidate the new paradigm.

Thus, after that, a first pioneer period went by, where marketplace models have attracted business managers and, consequently, finance

Figure 1.



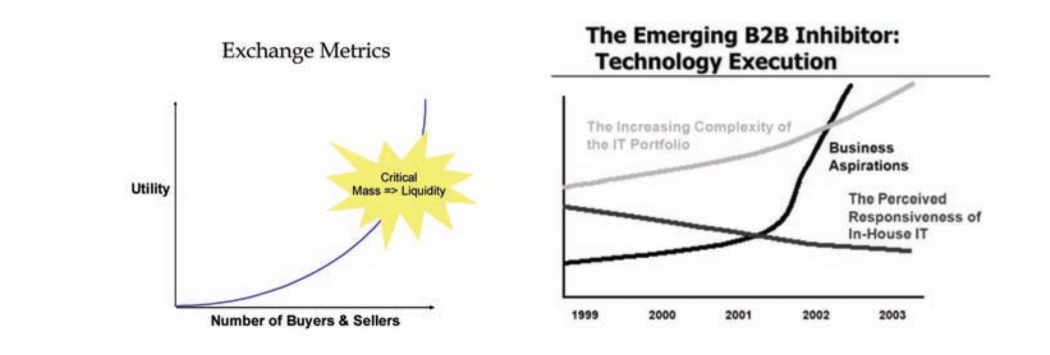
investors, showing the possible strategic value of Web technology, that is, the ability to extend the enterprise business model and to improve process efficiencies; now that paybacks have not been respected and investors begin to retire their support, the marketplace model must be readapted and reengineered (Bollier, 1996).

In order to better respect investors' and business managers' constraints and expectations, that is, to present a more realistic behaviour of the promised return of investment, it is now crucial for marketplace business models to take into account the following aspects:

- Membership and brand is more important than transaction fee (Dibb, Simkin, Pride, & Ferrel, 1991).
- Quality and quantity of services can aggregate other partners, which can bring additional financial resources and customers, in order to give more value to the industry they address.
- Processes begin before transactions and continue after it; support must be given to a wider range of customer tasks.

In the next pages two significant real implementation cases have been considered. The first concerns the possible evolution of a typical vertical marketplace positioned in the steel supply chain. The second shows how a service center for a geographical industrial district populated by many fragmented small enterprises can give value to the related supply chain and presents

Figure 2.



a valid paradigm to overcome possible "digital divide"-based approaches.

MAIN THRUST OF THE CHAPTER

Case Study 1: u-steel.com[1]

General Aspects

U-Steel is the first next generation e-marketplace, neutral, independent, and completely online, to be dedicated to the commerce of steel and related services. Initially launched in September 2000 by the strong sponsorship of a group of European partners such as COFACE (F), Falck Group (I), Mastr@ (I), Iperbusiness (I), Sopaf (I) and Mittel Generale Investimenti (I), U-Steel's aim is to bring the most qualified players of the steel industry online, increase the consumers purchasing power, and expand the markets.

From an operational perspective, U-Steel is an e-marketplace integrated with a large number of support services. Strategically, however, it is not just a virtual channel between buyer and seller but also an important tool to allow all supply chain participants to become a part, easily and safely, of the steel's industry future dynamics.

All effective members of the marketplace who purchase steel through U-Steel are certified and assigned a credit rating by COFACE, a worldwide leader in credit certification. Sellers who require total guarantee of their credits towards other U-Steel members can take out a credit insurance policy offered by COFACE exclusively to the portal's subscribers at extremely favourable terms.

When in 1999, as a group of friends, the founders came up with the idea of starting a company with the purpose of building an e-marketplace for steel, they immediately understood the huge importance of the project. Shifting to "virtual" steel meant entering a dimension completely new to the steel industry, traditionally tied to the business rules of the so-called "*old economy*."

In order to be successful, this new initiative required three elements: high level stockholders, capable of ensuring neutrality and independence to the marketplace; managerial staff knowledgeable in both the steel and the information technology industries; and finally, the most advanced technology available (Ansoff 1987; Hammer, 1996).

The idea was presented to a number of potential partners, all of whom accepted the project with great enthusiasm, starting from Iperbusiness of the TC Sistema Group, who became the technology partner, taking responsibility for the coordination of the project and the system integration requirements.

U-Steel has chosen a business model mainly based on the concept of *membership*, despite other initiatives based solely on the transaction mechanism. In an industry like steel-working, which only in Europe claims a turnover of approximately 285 million Euros, U-Steel's further objectives is to bring together partners who have a technologically innovative offering, placing particular emphasis on the technological brand.

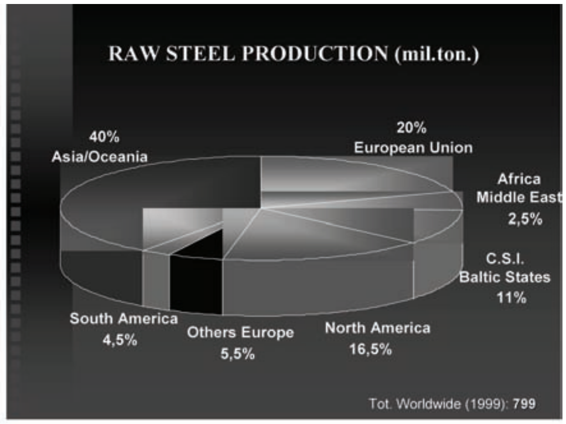
The marketplace starts off as a platform on which a number of additional services can be included; the objective is to increase the offering based on the efficiency of the cycle with other services ranging from insurance, credit, and logistics, all the way to integrating the partner's IT infrastructures with a technology across platforms.

U-Steel's transactional system is globally among the most advanced, with a variety of exchangeable products including plate, coil, rod, wire, pipe, and special irons and steels. Additionally, there is the possibility of marketing excess lots or scrap lots for the plants.

When a purchaser wishes to find a potential seller, they choose the product to buy, select the supplier, and can contact them through the marketplace to establish prices and terms by means of an interactive chat.

This way U-Steel becomes the point of contact between purchaser and seller, the location where the negotiation is conducted and finalized, regard-

Figure 3.



less of where in the supply chain the negotiation takes place. The model allows considerable savings in terms of time, cost, and back-office infrastructure.

But the portal is not only about buying and selling; this is just the initial step of an online process to which it will soon be possible to add additional services such as invoicing, logistics, warehousing, management and handling, accounting, and credit management.

Overall, a system capable of handling all processes not strictly connected to the steel's core business.

Who are the players interested in accessing the marketplace? The system potentially involves all components of the cycle, from the manufacturers to the retailers, from service centers who purchase large amounts and resell smaller lots of semifinished product, to the retailer or storekeeper who distribute the product to end users.

U-Steel does not promote disintermediation. On the contrary, it encourages the repositioning of sales figures who previously benefited from the inefficiencies of the supply chain and for whom it is now possible to become value added consultants. A trading tool only adds another level of competition within the procurement process.

A seller approaching U-Steel is given the opportunity of publishing the seller's catalogue directly on the marketplace, complete with prices and current available stock, or with the option of showing only the products without any further

Figure 4.

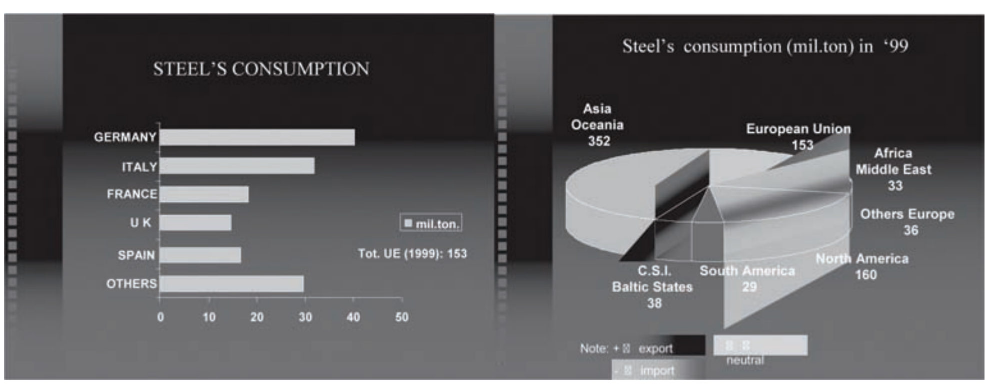


Figure 5.

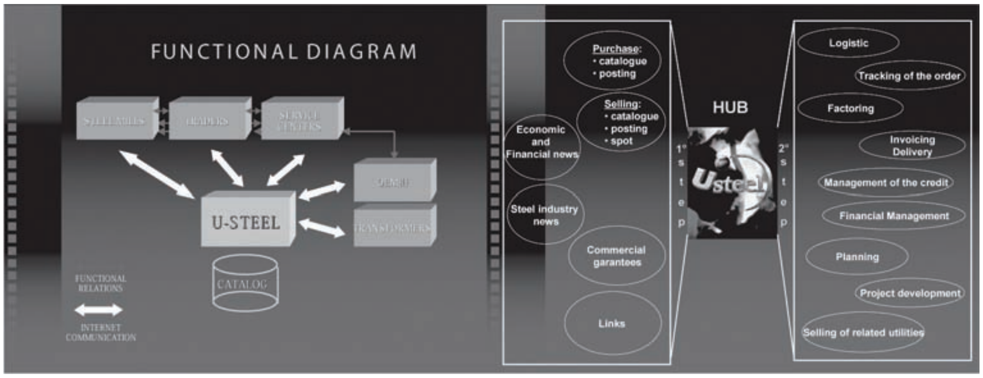


information. In both cases, the subscriber is given the possibility of integrating the U-Steel catalogue with the seller's own information system so that each transaction results in a warehouse operation, a production cycle advancement, or a purchase order.

Alternatively, the manufacturer may simply replicate a portion of their product catalogue, put it online, and choose when to synchronize the two systems.

The technological components was chosen, developed, and implemented by Iperbusiness on the BroadVision application. Hewlett Packard was chosen as outsourcer of all the systems management services, including the environment infrastructure (i.e., premises, power supplies and surge suppressors/generators, security systems, fire prevention, local area networks, etc.) and the required hardware platform housed in the HP Data Centre located in Bergamo (I).

The system, designed and commissioned in just 4 months time, is based on a UNIX HP UX operating system, is configured on two HP9000 A400 clustered Web servers, two HP9000 A500 to run the BroadVision applications, and an HP9000 A500 box acting as DB server with the Oracle database. The information is stored on two HP SureStore ESC10 clustered devices with an HP SureStore E 2/20 backup library.

The network is based on two Cisco 2900 routers, a Cisco Local Director 416 firewall, and a Cisco PIX 525 in failover. The entire system was designed to provide the highest level of availability, and with doubled security and load balancing systems, it was built to handle an initial volume of 1.200 users in its first months.

Furthermore, HP specialists handle all the system resource administration activities ensuring the users' seamless and transparent functionality.

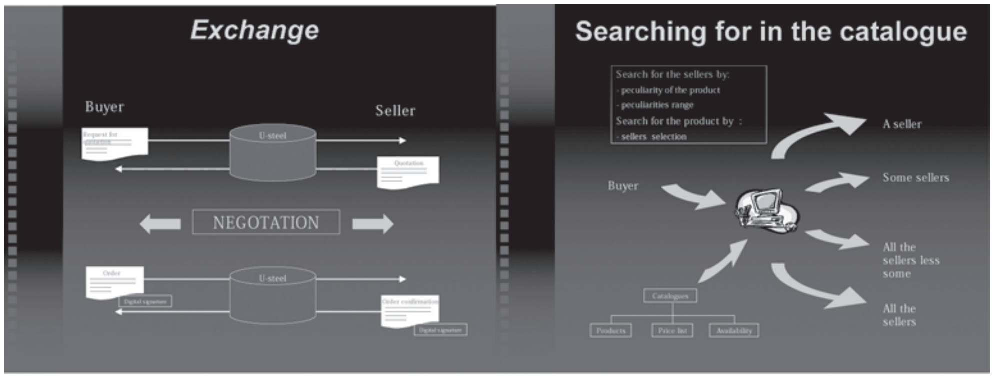
The E-Business Model

The business model of *u-steel.com* is based the on typical characteristics of the European steel supply chain and on the model of a B2B marketplace.

The European steel supply chain is formed by a very limited number of large steel producers and brokers, which are positioned at the top links of the chain, and by a great deal of other smaller players, grouped in dealers, steel service centers (SSC), and final companies which transform and use steel components in their own production. Even though this supply chain includes the presence of large producers, brokers, and even buyers (e.g., large automotive industry enterprises), the typical power play is well balanced, in that, medium and small companies can usually buy steel also oversee, that is, in America and Asia.

Thus, u-steel.com, which includes among its partners ex-business managers of the steel chain

Figure 6.



who know very well the market and the industry behaviour, is positioned as a vertical, *neutral*, *independent*, *aggregating*, and *collaborative* electronic market maker for steel trading exchanges and other services, in order to satisfy the needs of all the players and to support all the competitive forces of the steel supply chain.

Thus, first of all, u-steel.com is a vertical marketplace, which implements typical processes of a well identified market and industry where trading activities are accomplished in a particular context.

It is *neutral*, in that it is neither “seller” or “buyer” advocated. It offers to both the groups of players an electronic trading place where it enables secure commercial transactions and other services. Buyers and sellers can access the site and operate it using the typical trading approaches: catalogue searching and sourcing, online and even interactive exchange, and offer-posting processes.

The expected macro-benefits produced through these approaches can be grouped in the following main classes:

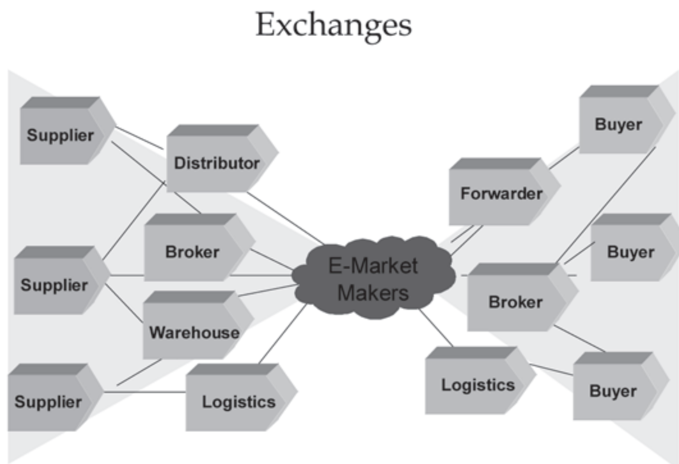
- Improving efficiency of intercompany operational processes by reducing the typical time usually needed to manually accomplish the same tasks.
- Enhancing commercial visibility and exploitation of resources, particularly for Steel Service Centres and small dealers, which can reach a larger audience of final transformers.
- Reducing buying cost, in term of final price, for small and medium transformers that can increase their ability to compete.
- Reducing stocking and work-in-progress costs of the whole supply chain through a better synchronization of production, distribution, and delivery.

Furthermore, taking into account the peculiarity of the European steel supply chain, U-Steel will offer in the immediate future a very sophisticated auction-based system, which will give the opportunity to large producers (i.e., steel mills a brokers) to launch forward actions on the European market and which, at the same time, will provide to small dealers and transformers with a mechanism of reverse actions to buy at better conditions also on oversee marketplaces.

U-steel is also an *independent* electronic market maker, in that it lies in a well-balanced power play position. Its claimed mission is “acting as informediary on the steel market,” with no particular preference for any side.

The historical role of shareholder partners ensures both the knowledge of the steel supply chain, through the Falck Group currently involved in the utilities industry, and the absolute transparency

Figure 7.



and independence, being the others well known players of other industries.

But U-Steel is an *aggregating* and *collaborative* market maker as well. These issues represent the innovative aspects of the U-Steel business model.

In fact, after the "hype cycle" of the connected economy has shown failures and constraints of an expected "no limits" growth, U-Steel proposes a further possible direction in a marketplace model evolution. U-steel offers other services by aggregating other business partners and delivering new functionalities which create new value for the steel business community.

There are two types of services that U-Steel delivers: business services and technological services.

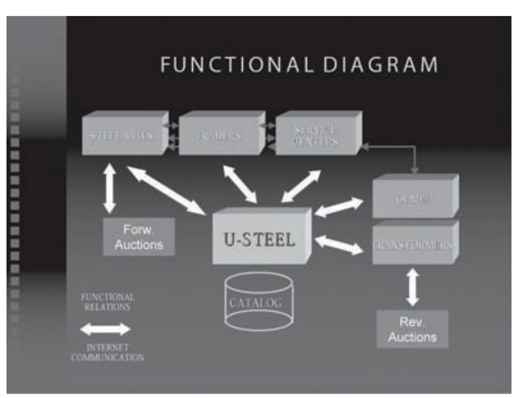
Business services include

- Credit insurance (already delivered at the moment)
- Logistics delivery

Technological services include

- Process integration
- Platform outsourcing

Figure 8.



Credit insurance gives the opportunity to sellers to insure their credit, following a credit rating mechanism classified and tuned by Coface (F), one of the worldwide insurance market leader and one of the U-Steel shareholder. Through these functionality, the seller can decide to insuring the seller's credit and thus electronically activate the operation with an automatic interaction with the Coface credit system, in order to assess and possibly accept economic conditions, as proposed by Coface. The seller pays a further transaction fee for that.

Logistics delivery, which is not currently available, but it will be in the future, will give the possibility to the buyer to choose a possible logistics and transportation player to be electronically involved in the process in order to deliver goods in a specified spell of time.

Process integration means the availability of integrating, when needed, the information system of both seller and buyer, in order to automatically accomplish several collaborating processes, such as procurement, fulfilment, billing, and invoicing through an XML interface. It means also the possibility to be integrated with other marketplaces supporting the same feature in order to extend the catalogue interaction to other "ecosystems."

The most innovative *collaborative* aspect of U-Steel is the availability of a technological platform, which can be rented by supply chain players. The technological platform on which U-Steel is based is a very flexible architecture provided by BroadVision and Oracle "best of breed" components. It ensures the possibility to build separate and independent environments where different players can implement their corners. In this way, a steel mill company or a broker, for example, can also deliver their own extranet, outsourced to U-Steel, avoiding the investment of a huge amount of money in a capital expenditure which would ask them for large financial resources and would force them to track a control on the return of investment.

In this model, on the contrary, U-Steel has the possibility to reduce this payback time and thus to shrink its ROI, while other players receive the value to have their own environment, classified as a variable cost in their profit and loss account. In other words, U-Steel can reduce the initial trade-off between revenues and costs and the other players using the feature, use the platform as a general expenditure, and do not have to directly involve themselves in technology, which is not their core business.

In this sense, the U-Steel model appears as a vertical model for trading and commercial operations, and, at the same time, as a horizontal model for distributing technological skills and services; a sort of a hybrid, new model, where U-Steel can act as a business service provider as well. A model that, taking into account the current evolution of other vertical marketplaces in other industries, can be considered a valid evolution and a possible successful paradigm.

The Revenue Lines

The U-Steel model is built on the following economic revenue lines:

- Membership fee, which is an annual fee to be paid by sellers and buyer in order to operate on the marketplace.
- Transaction fees on goods, as a percentage of the total amount.
- Transaction fees on services delivered by other partners (credit and logistics).
- Annual fee for ERP integration, following defined technological standards.
- Annual BSP fee, which is a yearly based fee for using the platform hosted by u-steel and adequately customized on customer needs.
- Advertising.

U-Steel will involve more then 6,000 European users after 3 years and will trade more then 5 millions of steel tons in the same period (3% of the whole European market). Expected revenues will be over 40 Millions Euro at the third year.

The www.u-steel.com site, which is currently available for test purposes to a limited community of "family and friends" players of the steel supply chain, will be launched and delivered worldwide on June 20, 2001.

Case Study 2: up2gold.com[2]

General Aspects

Up2Gold.com is a service center conceived to deliver consulting and technological services to the supply chain of gold and silver manufacturing located in Arezzo (I). Arezzo is one of the most important industrial sites for gold and silver manufacturing, a typical Italian industrial district which geographically groups many SMEs belonging to the same supply chain.

At the starting point of the gold (and silver) supply chain there are the raw material suppliers, that is, larger companies which are in a limited number, while production plants are divided into a plethora of small and very small companies linked together by complex multidirectional channels.

The distribution layer is, again, a "long chain" where various intermediaries and dealers are involved before reaching the end user.

These large companies control the supply links and schedule main production flows, while large dealers mainly govern the sales channel and, in particular, the export market.

As mentioned before, the productive part of the supply chain is very fragmented and powdered in a myriad of SME, involved in production subphases mainly as third parties. As it is usual in these cases, they do not participate to the research and development process; they just execute and manage orders received from other supply chain links.

These enterprises are often familiar companies, involving even less than 10 persons and unable to base their activities on some information system, which would be useless yet.

The final production output is finished goods like gold chains, rings, and ear-rings. The product is considered to be medium quality goods, usually competing with Indian and Far East equivalent productions.

Such a supply chain, despite its pervasive presence in many other sectors, is obviously inefficient, for the following reasons:

- The main obstacle to a more efficient chain is, as said before, the dimension of the company involved, the number of companies, and the related fragmentation.
- Moreover, the efficiency of the chain seems to be influenced by the flow of information regarding stock or availability of goods or raw material. In fact, while the commercial side of the chain (the end) does not know the availability, prices, quality, and other information, the producers do not know the real needs of their markets in order to be able to adequate their production volumes, stiles, and so forth.
- The third type of inefficiency is linked to the sales forecast or production schedule, which are extremely difficult to govern, because of a very fragmented catalogue of products; is very common the case of a catalogue with more than 10,000 articles, and practically every company has a catalogue of thousands of articles. Moreover, many articles are subject to season waves, other are linked to styles and stylists.

The result of these inefficiencies are, of course, poor service at the end user level (e.g., unavailability of products in certain period of the year) or, which is worst due to the cost of raw gold, obsolescence of the entire stock with the consequent inefficiency at the producer level. This also causes lack of competitive presence in those markets where the newcomers are getting more and more aggressive due to a lower production cost and a more flexible supply chain.

In order to better understand the subject, the

Table 1.

Site	**1-9 workers**	**10-49 workers**	**50-99 workers**	**100-999 workers**	**Total**
Arezzo *Companies* *Workers*	991 3366	269 4547	7 423	4 1279	1271 9615

Arezzo's gold and silver supply chain is described in Table 1.

Arezzo's supply chain shares the 20% of that global export, that is, more than 1.500 billion ITL. The total Arezzo's gold and silver production is more than 6.000 billion ITL.

The aim of up2gold.com is to offer a class of services to overcome the inefficiencies described above through the deployment of the a service center able to deliver:

- Consultancy services to help managing personnel, legal, and work trends issues;
- ERP services, with particular stress on an accounting and payroll application.
- A B2B supply chain marketplace to exchange raw material, semifinished goods, and human resources work availability and to interconnect along the chain goods' availability and stocks.
- A B2C marketplace, sell side-oriented, in order to increase sales of medium size companies.

The shareholders of the Up2Gold are:

- Arezzo's and National artisans associations (CAN).
- TC Sistema SpA and Datamat SpA, two famous IT players of the Italian market;
- FlyNet, a local ISP.
- Banca dell'Etruria e del Lazio, which is a local bank.

General concepts and strategic issues of the center have been designed in the following terms:

- The marketplace model appears innovative and suitable to fit chain needs and SMEs' expectations.
- It can be considered as a new paradigm for supply chain local systems and exported and disseminated to other SMEs districts; a real B2B best practice.

Table 2. The total Italian production export of gold and silver goods is shown.

Region	**Production export 1989 (billions ITL)**	**Production export 1999 (billions ITL)**
Europe	1173 (28.15%)	2323 (28.76%)
North America	1684 (40.41%)	2694 (33.36%)
Latin America	175 (4.20%)	634 (7.85%)
Middle East	468 (11.23%)	747 (9.24%)
Far East	379 (9.10%)	860 (10.65%)
Others	288 (6.91%)	818 (10.13%)
Total	4167 (100%)	8076 (100%)

The E-Business Model

When considering the business model of up2gold.com, it is necessary to underline that the company is a service center which delivers a set of services supporting a supply chain. It means that the center offers traditional B2B services along with "connected economy"-like functionalities.

Yet, even though the business model of the center is very articulated and all of its components should be considered and analyzed in a broader perspective, for the purposes of this chapter we would like to draw the attention to the marketplace part, which is an innovative B2B model and includes elements of as the supply chain management approach.

When addressing this marketplace, it is necessary to take into account typicality and behaviours of the supply chain to which it belongs. As already mentioned before, the Arezzo's gold chain is a very fragmented network of small suppliers all working for a few larger enterprises, which act as raw material suppliers and distribution channels (Fariselli, Oughton, Picory, & Sugden, 1997). These companies control the chain and play a strong power role: they make the research and development, that is, design gold and silver final products, schedule large scale production (distribution and sale channels, in particular), and control the raw material procurement process (raw material suppliers). They usually involve the other links of the chain as third parties, requesting them to produce finished or semifinished goods by a well defined delivery date (make-to-order).

This links, on their turn, involve other links of the supply chain, ordering subcomponents and other semifinished goods, scheduling delivery dates, and so on along the whole supply chain. All the subproducers links must generate by and large the following tasks:

- Procuring raw material, buying it in general from large raw material suppliers.
- Procuring human resources or other smaller production companies.
- Procuring semifinished goods, if any, from other chain players.
- Producing components as ordered.
- Delivering goods.

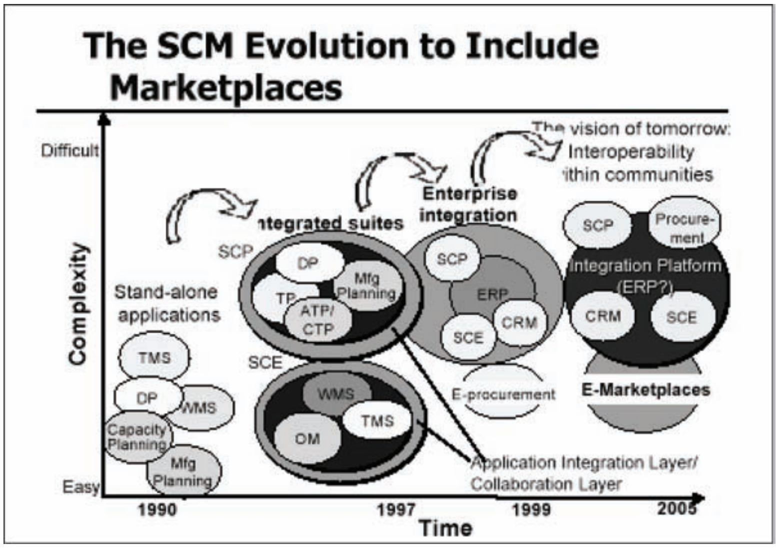
The value of information in accomplishing these activities is very high; if existing, it would reflect in a larger economy of scale, and in a better stock and delivery efficiency. Sometimes it happens that sale channels must refuse oversee orders, in that they are not able to declare on time a right delivery date and final prices to customers, for a lack of updated information!

These activities are not supported by an integrated information system and this fact, as already mentioned above, generates inefficiency to the whole network chain.

Up2gold.com is building a marketplace which offers two important services to the companies:

- A typical exchange marketplace in order to accomplish the first three activities as described above: procuring raw material, semifinished goods, and human resources. This marketplace gives raw material suppliers the ability to exchange gold and silver and give other enterprises the possibility to buy possible semifinished goods from others' stocks and/or human working resources availability. An additional auctions and reverse auctions system is included in order to sell stocks or buy components at a more convenient price.
- A collaborative system to support a supply chain management marketplace. Through this remote system, accessed via Web, any company, even small enterprises, can give their availability-to-promise, by claiming their actual stock availability, production capacity and, of course, prices. This system can give the sale channel an immediate

Figure 9.



picture of both the order progress status and the possible make-to-order availability of the whole supply chain.

The model that up2gold.com implements is not exactly that of a supply chain management marketplace, in that production orders scheduling is not taken into account. It is a sort of warehouse and stock availability integration, useful to catch up-to-date information before and after the order is assigned. "Before the order" means that the sale channel can assess and verify possible online availability along the whole supply chain and possible delivery dates to communicate to customers. "After the order" means that the sale channel and other links of the chain can assess online the real progress status of orders, controlling the actual delivery date.

This model is very simple in that no information system is required for SMEs; they are only requested to keep their order profile updated by entering simple information at the up2gold.com site.

Up2gold.com conceived this marketplace model in order to match actual requirements of SMEs-based supply chains, that is, the typical Italian industrial chains. Up2gold.com named this model *partner chain management* (PCM).

The Revenue Lines

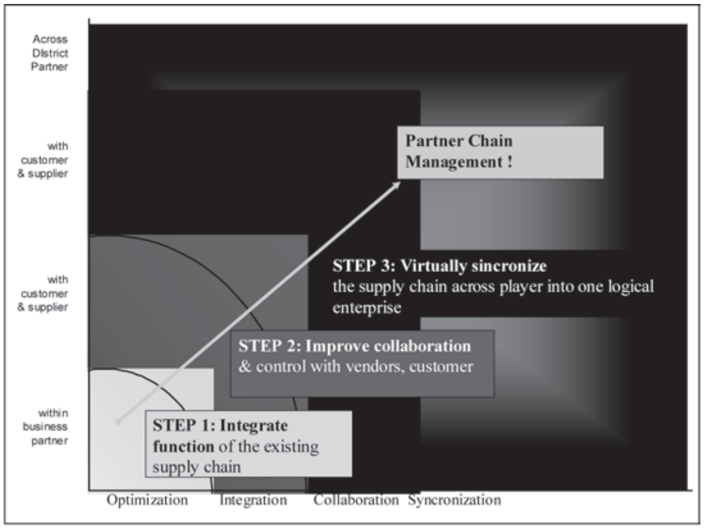
The Up2Gold model is built on the following economic revenue lines:

- Membership fee, which is an annual fee to be paid by any company in order to access the center services.
- Transaction fees on goods, as a percentage of the total amount.
- Annual fee for consulting and ERP function access.
- Advertising.

Up2Gold will involve more then 1.200 district companies after 3 years; the value of transaction involved will be more then 1.000 billion ITL.

The current site is only for presentation and advertising purposes. The service center will release its services progressively, starting at the beginning of 2002. The marketplace in particular will be launched and delivered by the first quarter of 2002.

Figure 10.



FUTURE TRENDS AND CONCLUSION

The B2B e-marketplaces will represent in the future the new efficient paradigm that will be used to accompany all trading process concerning goods, commodities in particular. They will be the "low cost" arenas where large companies will invite their provider to submit proposals at the best prices. But they will also be the "low cost" arenas where SMEs will present their products and their brands in order to be known and contacted by a larger and larger audience. E-marketplaces will more likely act per industry, instead of being "cross-industry, general purpose," and will show the two natures as previously mentioned, that is:

- Organized and driven by a large enterprise that will use the e-marketplace in order to attract a great number of suppliers, globally widespread, and able to enhance their good value proposition. This will ensure a strong competition and low supply prices.
- Organized and driven by communities (associations) particularly composed by small enterprises that will group their efforts in order to make their brand and their products more globally known as possible. Through this mechanism, SMEs will also implement collaboration tools and instruments in a sort of "partners' chain network," where different facilities, such as marketing services, information systems, administrative, and financial services, can be shared at lower and more competitive internal prices by creating at the same time both efficiency and new dimensions of effectiveness.

ABSTRACT

Embedding rules into Web applications, and distributed applications in general, seems to constitute a significant task in order to accommodate desired expressivity features in such environments. Various methodologies and reasoning modules have been proposed to manage rules and knowledge on the Web. The main objective of the chapter is to survey related work in this area and discuss relevant theories, methodologies and tools that can be used to develop rule-based applications for the Web. The chapter deals with both ways that have been formally defined for modeling a domain of interest: the first based on standard logics while the second one stemmed from the logic programming perspective. Furthermore, a comparative study that evaluates the reasoning engines and the various knowledge representation methodologies, focusing on rules, is presented.

DOI: 10.4018/978-1-60566-402-6.ch016

1. INTRODUCTION AND MOTIVATION

Nowadays, with the evolution of traditional web of documents to a more complex web of services, an increasing demand for embedding intelligence to Web applications arises. In this context, the efficient management of knowledge seems to play a key role in order to achieve smart behavior of Web applications and to overcome several issues of such environment (e.g., information integration). Ontologies, mainly written with Semantic Web technologies, constitute a well-established paradigm for representing knowledge on the Web. Though, current efforts are focused on extending ontologies with more expressive forms of knowledge like rules. In fact, given the state-of-the-art in the realization of the Semantic Web vision, rules constitute the next prominent challenge. Since the ontology layer of the Semantic Web architecture stack has reached a sufficient degree of maturity through Web Ontology Language (OWL) (Dean et al., 2004), the next step of progress involves the integration of rules with ontologies, most of them based on subsets of First Order Logic (FOL).

Rules are capable of extending the expressiveness provided by ontology languages through the definition of more complex relationships between individuals. Additionally, as a modular form of knowledge, they fit well in domains like personalization, policies and business-to-business (B2B) interaction. However, it has been shown that extending ontologies even with simple forms of rules can lead to undecidability of key inference problems.

On the other hand, many business-logic applications have extensively taken advantage of existing rule management systems or solvers (Jess, 2008; ILOG, 2008; Drools, 2008), aiming at facilitating the knowledge management process. As a result, the success of rules in non-Web applications moved Web researchers to use traditional rule engines on the Web.

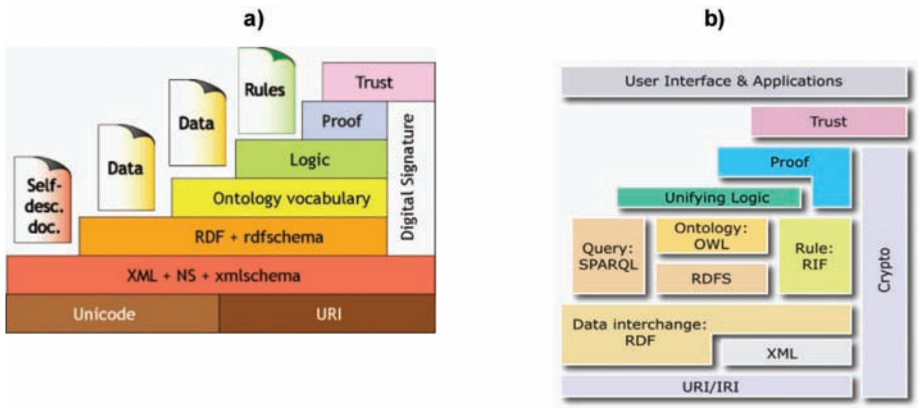
However, the aforementioned stable rule systems have not been originally created for open and heterogeneous environments like the Web. Such platforms have adopted different knowledge representation formalisms, mainly based on principles of logic programming, instead of classical logic. As a consequence, they differ from recent Semantic Web technologies in many aspects, including representational features and reasoning functionality, as well. Hence, building a rule-based application for the Web with existing rule technologies is not a straightforward task.

In the rest of this chapter, we provide foundational knowledge on this topic together with implementation issues, techniques and design patterns. Section 2 briefly describes how the things have gone so far in the area of Web knowledge representation formalisms. In Section 3, various knowledge representation methodologies and tools are discussed. Specifically, Section 3.1 demonstrates the different languages and formalisms, derived from both classical logic and logic programming view, while Section 3.2 focuses on various engines able to reason over such knowledge bases. Section 4.1 gives the main requirements for rule-based web applications. The evaluation presented includes both a qualitative comparison (Section 4.2) of the existing approaches and a performance analysis (Section 4.3) of current ontology reasoners and rule engines. Finally, several future trends and open issues are identified in Section 5. Hence, this chapter aims at becoming a helpful guide for applying rules to Web applications.

2. THE STORY SO FAR

The knowledge representation languages proposed (see Section 3.1) for representing knowledge on the Web are based either on the Classical Logic (CL) perspective or on Logic Programming[1] (LP). As a result, a debate was started between the Database community and AI researchers, respectively, in order to determine the more suitable of the two approaches in the formalization of Web knowledge. Additionally, different languages of the same perspective, providing various degrees of expressivity, have been proposed. Hence, the integration of knowledge with Web applications was more complicated. Recently, with the evolu-

Figure 1. a) Tim Berners-Lee Semantic Web layer "cake" and b) the latest form of Semantic Web stack diagram (adapted from W3C Semantic Web Activity, 2008)

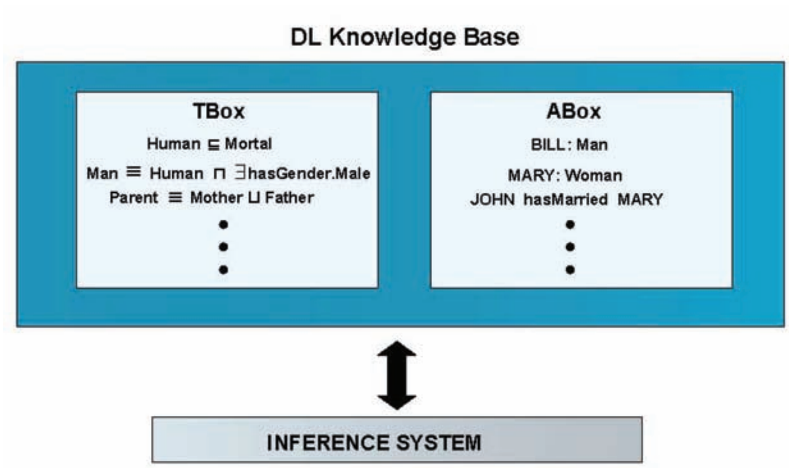


tion of Semantic Web technologies, these modeling paradigms have been extensively discussed by researchers (Motik, Horrocks, Rosati, & Sattler, 2006; Patel-Schneider & Horrocks, 2006; Eiter, Ianni, Polleres, Schindlauer, & Tompits, 2006a; Donini, Lenzerini, Nardi, & Schaerf, 1998; Antoniou, et al., 2005; Boley, Kifer, Patranjan, & Polleres, 2007).

Clearly, this confrontation also affected rules. Although, significant efforts have been devoted in order to develop appropriate rule languages for the Web (see Section 3.1), a debate between proponents of the different perspectives has appeared. The main argument involves the degree that rules would be combined with ontologies. Initially, as formulated by Tim Berners-Lee, it had been commonly accepted that Semantic Web should be structured in a hierarchy of layers that seamlessly interoperate (Antoniou & van Harmelen, 2004). However, some proposals (mainly stemmed from the database community) preferred to keep the rules and the ontology layer separated, in order to preserve expressiveness and decidability of reasoning process, as mentioned in (Eiter et al., 2006a). Specifically, in (Kifer, de Bruijn, Boley, & Fensel, 2005) the authors argue that the rules layer of Semantic Web architecture should be placed next to the ontology layer of the Semantic Web stack in order to take advantage of important rule languages based on logic programming. However, in (Horrocks, Parsia, Patel-Schneider, & Hendler, 2005) the authors criticize the aforementioned approach and denote that such a distinction would lead to two Semantic Webs based on different semantics. These discussions along with the Semantic Web Activity workgroup have led to several modifications of the stack. Figure 1 presents the initial and the current form of the Semantic Web stack diagram specified by the W3C Semantic Web Activity Group (W3C Semantic Web Activity, 2008).

The aforementioned facts gave rise to confusion inside the Web community. If the experts (i.e., the logicians stemming from both AI and databases) could not decide and recommend a unified framework for formalizing knowledge, how Web developers and users should choose the best language according to their needs? The current solutions are either to study the capabilities provided by all these languages (i.e., available expressiveness, support by existing reasoning engines, tractability etc.) or to exclude knowledge from their applications.

Figure 2. Architecture of a Description Logics knowledge-based system



3. KNOWLEDGE REPRESENTATION METHODOLOGIES AND TOOLS

This section surveys different knowledge representation methodologies along with reasoning modules that have been proposed for managing knowledge on the Web. After an overview of Description Logics that comprise the main formalism for representing ontological knowledge in Web applications, we focus on rules.

3.1 Knowledge Representation Formalisms

Description Logics

Description Logics (DLs) (Baader, Calvanese, McGuiness, Nardi, & Patel-Schneider, 2003) are subsets of first-order-logic, originating from semantic networks and frame-based systems. They constitute a family of knowledge representation languages that aim at providing well-understood mechanisms in order to formalize knowledge that describes a domain. This way, DLs are equipped with formal, logic-based semantics, emphasizing on reasoning process. Typical reasoning tasks include consistency checking of the knowledge base, concept satisfiability, instance checking etc.

A DL-based knowledge base is composed of two components: TBox and ABox. TBox contains the vocabulary of the application domain, called *terminology,* as well as axioms based on that vocabulary. Practically, such vocabulary consists of *concepts* and *roles*. Concepts are generic descriptions of sets of individuals, while roles constitute binary predicates for defining properties of the individuals. On the other hand, ABox includes assertions of individuals that may refer to either concepts or roles. For example, a statement declaring that a specific individual is instance of a concept resides in ABox, while a statement denoting that "every human is mortal" belongs to TBox. Figure 2 shows the generic architecture of a DL knowledge representation system.

Each description logic language is determined by a set of constructs, enabling the use of atomic concepts and atomic roles in order to define complex ones. These constructs directly affect the expressive power of the language and, thus, the complexity of inference tasks. As a result, the selection of the appropriate description logic language in order to describe a specific domain includes the examination of the imposed requirements for representation expressiveness.

DLs set up the base for the definition of Resource Description Framework (RDF) (Klyne &

Caroll, 2004), RDF Schema (Brickley & Guha, 2004) and Web Ontology Language (OWL) (Dean et al., 2004) that constitute W3C standards for representing knowledge on the Web. Specifically, RDF is a simple data model for representing information on the Web. RDF statements are expressed in the form of (*subject, predicate, object*) triples. A set of such statements can be viewed as a graph where the subjects and the objects of these statements constitute the graph nodes while the predicates correspond to the graph edges. RDFS is an extension of RDF for expressing simple taxonomies through the definition of class/property hierarchies and domain/range of properties. OWL is totally based on DLs and it comes in three species: OWL-Lite, OWL-DL and OWL-Full. OWL-Full is the most expressive OWL species, since it takes advantage of all the OWL language primitives. OWL-DL limits OWL-Full to a subset of OWL primitives so as to achieve efficiency of reasoning. Finally, OWL-Lite is a sublanguage of OWL-DL by restricting more its expressiveness.

Description Logic Programs

The expressiveness of Description Logic Programs (DLP) approach (Grosof et al., 2003) corresponds to a fragment of OWL defined by the expressive intersection of Description Logics and logic programming. This approach intends to define a mapping from DL to logic programming (specifically, Horn programs in which no function symbols, negation and disjunction are allowed) and vice versa. An instance of such a mapping in the case of conjunction follows:

$$C_1 \sqcap C_2 \sqsubseteq D \equiv D(x) \leftarrow C_1(x) \wedge C_2(x) \quad (1)$$

However, for the sake of decidability, DLP offers limited expressiveness, since the aforementioned mapping covers only a few DL-constructs (in particular, conjunction, disjunction and quantification restrictions). For example, Description Logic Programs do not cover negation in class descriptions nor fully support cardinality restrictions.

Semantic Web Rule Language

Semantic Web Rule Language (SWRL) (Horrocks et al., 2004b) is probably the most popular formalism in Web community for expressing knowledge in the form of rules. Specifically, SWRL is based on a combination of Web Ontology Language (OWL) (Dean, 2004) and Rule Markup Language (RuleML) (RuleML, 2008) and has been proposed as a W3C candidate standard for formalizing the expression of rules in Web context. Contrary to DLP, SWRL extends OWL-DL with a specific form of Horn-like rules.

The proposed rules are in the form of an implication between the body and the head of the rule. A typical SWRL rule can be of the following form:

$$a_1 \wedge a_2 \wedge \ldots \wedge a_n \rightarrow b_1 \wedge b_2 \wedge \ldots \wedge b_m \quad (2)$$

where a_i and b_i are OWL atoms of the following forms:

- Concepts, e.g., C(x), where C is an OWL description, in general, and x is either a variable, an OWL individual or a data value.
- Object properties, e.g., P(x,y), where P is an OWL property and x, y are either variables, individuals or data values.
- Datatype properties, e.g., P(x,y), where P is an OWL property, x is variable or individual, while y is a data value.
- B(x1,x2,…), where B is a built-in relation and x1, x2, … are either variables, individuals or data values.

- sameAs(x,y) or differentFrom(x,y) where x, y are either variables, individuals or data values.

The main advantage of SWRL is the simplicity it offers, while extending the expressiveness of OWL. Another benefit of SWRL is its compatibility with OWL syntax and semantics, since they are both combined in the same logical language. On the other hand, extending OWL-DL with SWRL rules leads to undecidability of simple inference problems. A possible solution of this problem is presented in (Motik, Sattler, & Studer, 2005) which introduces the notion of *DL-safe* rules. Specifically, that approach restricts the application of SWRL rules only to individuals of the ABox part of the DL knowledge base. Moreover, SWRL does not support negation (neither classical nor negation as failure - NAF) and disjunctions. Finally, there is no efficient support of first-order provers to execute reasoning over SWRL. Usually, the SWRL rules are translated to existing rule systems (e.g., Jess (O'Connor, Knublauch, Samson, & Musen, 2005)) that handle the reasoning tasks partially, since they are not aimed to manage knowledge expressed in terms of first-order logic or subsets.

In the case of a Web service composition paradigm, some SWRL example rules could be the following:

$$\text{profile:hasOutput(?S1,?out)} \wedge \text{profile:hasInput(?S2,?in)} \wedge \text{process:parameterType(?in, ?cin)} \wedge \text{process:parameterType(?out, ?cout)} \wedge (\text{rdfs:subClassOf(?cout, ?cin)} \vee \text{rdfs:subClassOf(?cin, ?cout)}) \rightarrow \text{composableWith(?S1, ?S2)} \quad (3)$$

The abovementioned rule captures the knowledge that a web service S1 is composable with a service S2, if an input of S1 is either subclass or superclass of at least one output of S2. This rule uses specific namespaces of OWL-S ontology like "profile" and "process".

Answer Set Programming

Answer Set Programming (ASP) (Gelfond & Lifschitz, 1991) is a paradigm for knowledge representation and declarative programming. It has several advantages compared to other logic programming paradigms (e.g., Prolog) such as:

- *Full declarativity*: the order of rules in a program is not important.
- *ASP programs are in general decidable*
- *Non-monotonic inference*: both negation as failure (NAF) and strong negation are supported, thus enabling default reasoning and reasoning under the Closed World Assumption (CWA).
- *Availability of efficient solvers*: there are several ASP solvers that are scalable enough to deal with large knowledge bases.

A general ASP rule is of the following form:

$$a_1 \vee a_2 \vee \ldots \vee a_n \leftarrow b_1 \wedge \ldots \wedge b_k \wedge \text{not } b_{k+1} \wedge \ldots \wedge \text{not } b_m \quad (4)$$

where a_i and b_j are literals (atoms or strong negations of atoms) and *not* denotes NAF.

A set of such rules is an ASP program. What is interesting is the fact that these rules can have disjunctions in their head. This is a very important feature of ASP, since it introduces non-determinism in the inference process (i.e., an ASP program may have several models which are called *answer sets*).

In order to be able to use ASP on the Web, the ASP rules should be combined with Web knowledge. Since ontologies is the most common way to represent knowledge on the Web, an interaction between ASP programs and ontologies is deemed necessary. A solution to this integration problem is description-logic programs (or dl-programs). These consist of ASP rules that may contain queries to DL knowledge bases. For example, the following rule "brings" into the ASP program all instances of the class MovieTitle in the DL knowledge base:

$$\text{movie}(X) \leftarrow \text{DL}[\text{“Movie”}](X). \tag{5}$$

Several extensions to dl-programs were proposed (and implemented) so that they become more "suitable" for open environments like the Web, where information may be expressed in many diverse ways (e.g., multiple different ontologies). The most well known extension is HEX-programs (Eiter, Ianni, Schindlauer, & Tompits, 2005), which enable handling knowledge expressed in various formalisms, even with potentially different semantics (e.g., RDF(S) and OWL). HEX-programs contain several features (e.g., higher-order logic features) that enable more flexible integration with external knowledge bases. These extensions result in new syntax elements. For example, the atom *&rdf[u](s,p,o)* evaluates to true if <s p o> is an RDF triple asserted at URI u. Finally, another advantage of HEX-programs is that they allow using external data processing services that logic programming cannot handle (e.g., string processing). An interesting engine for HEX-programs is dlvhex[2] which is described in Section 3.2.

There have been proposed ASP-based several applications in the context of (Semantic) Web. One of the most promising is Web service composition (Rainer, 2005). The authors apply ASP techniques to "build" service compositions from available services that match a certain service request.

Web Service Modeling Language (WSML)

WSML (de Bruijn et al., 2005) is a language of representation languages for the Semantic Web. These languages are based on several different formalisms such as Description Logics, Logic Programming and First-Order Logic. Some of the basic variants of WSML are the following:

- **WSML-Core:** A subset of a Description Logic which falls inside the Horn logic fragment of FOL. It supports subsumption reasoning and query answering.
- **WSML-Flight:** An extension of WSML-Core which also supports full Datalog rules, default negation and integrity constraints. It can provide query answering in the context of Logic Programming.
- **WSML-Rule:** An extension of WSML-Flight with support for function symbols and unsafe rules.

Reasoning for these WSML variants can be implemented by several Logic Programming engines. For some features of these languages, DL reasoners can also be used or First Order theorem provers. These languages have been extensively used in several European projects, mainly in the application domain of semantic web services. Hence, several APIs, tools and other facilities are available for building WSML-enabled applications.

Defeasible Rules

Defeasible logic (Nute, 1994) is a rule-based, non-monotonic approach able to deal with incomplete knowledge and inconsistencies. These features have been widely remarked in the context of realizing Semantic Web vision, mostly in information integration areas (e.g., ontology merging). As a result, some efforts in research community (Antoniou, Billington, Governatori, & Maher, 2001) were devoted to carry the advantages of defeasible logic in the area of Semantic Web technologies.

The main idea behind defeasible logic reasoning systems is the ability to handle a number of additional features with regard to classical rules like priorities of rules, default inheritance, exceptions, etc. There are three different types of rules in a defeasible logic reasoning system: a) classical rules (called *strict rules*), b) *defeasible rules* that can be contradicted by other rules and c) *defeaters* used to specify exceptions of defeasible rules. This way, an important aspect achieved by such reasoning modules is their capability of resolving the possible conflicts that arise among defeasible rules.

Classification of Approaches Integrating Ontologies and Rules

Although several approaches have been discussed for combining rules with Semantic Web ontologies (Horrocks et al., 2004b; Grosof, Horrocks, Volz, & Decker, 2003; Eiter, Lukasiewicz, Schindlauer, & Tompits, 2004; Bassiliades, Antoniou, & Vlahavas, 2006; Rosati, 2006a; Rosati, 2006b), there is no totally accepted solution in the field. The main topic of argumentation is the degree of integration between the ontology layer and the rules layer. In this section we intend to provide a brief classification of the proposed approaches.

Two main categories of integration approaches have been distinguished in this context:

a. **Homogeneous approaches.** These approaches suppose a tight semantic integration of the two layers. Specifically, both ontologies and rules are embedded in a common logical language, permitting predicate sharing in a coherent way. In such approaches, ontology concepts and properties may be defined through rules. The most typical homogeneous paradigm is the combination of SWRL rules with OWL ontologies. This is also the most In addition, Description Logic Programs (DLP) (Grosof et al., 2003) constitutes another similar approach.
b. **Hybrid approaches.** These approaches correspond to a strict semantic separation between ontologies and rules. In particular, this strict separation concerns the rule predicates and the ontology elements. Hence, the vocabulary (concepts and properties) offered by the ontologies is used as a conceptualization of the domain and rules cannot directly define ontology classes or properties. Many integration approaches adhere to this category, including Answer Set Programming (Gelfond & Lifschitz, 1991), *dl-programs* (Eiter et al., 2004) and *DL+log* (Rosati, 2006c).

The user may find more details on this topic in (Eiter et al., 2006a).

Table 1 summarizes the aforementioned knowledge representation languages and their basic features.

3.2 Reasoning Engines

In this section we intend to provide the reader with a comparative feature analysis of existing reasoning modules, including description logic reasoners and rule engines, as well.

Jena2 (McBribe, 2002) is the second generation of Jena Semantic Web programming toolkit, which is a Java framework for developing applications based on Semantic Web technologies. Specifically, Jena provides an Application Programming Interface (API) for creating, storing, managing and querying RDF graphs as well as RDFS, OWL ontologies in various formats (RDF/XML, N3 and N-triples). The RDFS reasoner included in Jena framework does not support datatypes and blank node entailments. The built-in OWL reasoner is very limited, since it is a rule-based implementation of OWL-Lite. However, Jena is supplied with an interface which facilitates the connection and interoperation of the framework with any external reasoner that supports the DIG (DL-Implementation Group) standard (Bechhofer, Moller, & Crowther, 2003). Hence, the API provided by Jena could be integrated with most of the existing description logics reasoners. Furthermore,

Table 1. Basic features of various knowledge representation languages

Feature Language	Logical Foundation	Decidability*	Serialization formats
OWL	Classical Logic (FOL subset)	OWL-Lite: decidable OWL-DL: decidable OWL-Full: undecidable	XML/ N-triples (textual)
OWL + SWRL	Classical Logic (FOL subset)	undecidable	XML
DLP	DL and LP intersection	decidable	textual serialization (in terms of rules)
ASP	Extension of LP (disjunction in rule heads, DL queries)	decidable	textual serialization (in terms of rules)
DL+log	DLs + Datalog rules (disjunctive, non-monotonic)	decidable	textual serialization (in terms of rules)

Note: *regarding key inference problems (e.g., consistency of the knowledge base)

Jena provides a query engine in order to execute SPARQL (Prud'hommeaux & Seaborne, 2005) queries over RDF graphs.

RacerPro system (RacerPro, 2008) is the commercial[3] extension of Racer (Haarslev & Moller, 2001), which is probably the most popular reasoning engine for OWL ontologies to practitioners of Semantic Web technologies. RacerPro can be seen as a knowledge-based repository that can handle and it is a system for managing OWL ontologies, in particular. It implements the DIG interface and it offers an optimized tableau calculus for the description logic SHIQ(D). Additionally, it supports qualified cardinality restrictions as well as some extensions of OWL (e.g., OWL-E (Pan & Horrocks, 2004) except user defined XML datatype expressions). Moreover, the latest version of RacerPro includes a first implementation of an SWRL rule engine.

Pellet (Sirin, Parsia, Grau, Kalyanpur, & Katz, 2007) is a Java-based, open source reasoner capable of handling expressive OWL ontologies. It implements an optimized tableau algorithm, augmented with a number of additional features (e.g., support for Unique Name Assumption - UNA, closed world reasoning, SPARQL query answering). Pellet also provides an explanation service in order to facilitate the debugging of the ontology engineering (Parsia, Sirin, & Kalyanpur, 2005). Although typical reasoners detect the inconsistencies between concepts of the knowledge base (KB), Pellet can explain *why* a concept description led to unsatisfiability. This way, the reasoner provides user with additional knowledge (e.g., relevant axioms or restrictions) sufficient to understand the problem and reform the KB properly. Finally, Pellet allows ontologies to use XML-Schema built-in and user-defined datatypes that extend numeric and date/time types.

Bossam (Jang & Sohn, 2004) is a RETE-based, forward-chaining reasoning module for reasoning and querying over RDF(S) and OWL documents, while it also supports rules execution (SWRL rules are included). It is based on Logic Programming (LP), augmented with some expressiveness features stemming from First-Order-Logic (FOL). For example, a number of additional to LP features are provided by Bossam, including support for both classical negation and NAF and disjunctions in the body of rules. Hence, it does not support complete reasoning over OWL Ontologies. Furthermore, it facilitates the integration of rules with Java by supporting a procedural attachments mechanism for SWRL rules. Finally, Bossam provides an API for managing the engine, loading ontologies and rules, querying RDF(S)/OWL documents and giving explanations about derived facts. Currently, Bossam does not support SPARQL query answering, while the serialization of the knowledge base to a persistent store (e.g., file system) is another missing feature.

FACT++ system (Tsarkov & Horrocks, 2006) is the descendant of FACT (Horrocks, 1998). Contrary to the lisp-based FACT system, FACT++ is an open source reasoner for SHOIQ(D) implemented in C++. It is based on tableaux algorithms in order to provide both TBox and ABox reasoning tasks and it can be accessed through the DIG interface. It also supports a number of additional features like handling enumerated classes (a.k.a. nominals) and it is a very efficient TBox reasoning engine. However, the main disadvantage of FACT++ is its inefficiency to support complete ABox reasoning. Hence, FACT++ is unsuitable to applications that call for instance classification and retrieval.

KAON2 (KAON2, 2008) is the successor of KAON Project (KAON, 2008) and unlike pure description logic reasoners, KAON2 does not implement a tableaux algorithm. In fact, KAON2 is a hybrid reasoning module able to handle both ontologies expressed in description logics terms and Disjunctive Datalog programs. It implements algorithms that reduce description logic SHIQ(D) to Disjunctive Datalog (Hustadt, Motik, & Sattler, 2004), taking advantage and applying well-known practices stemming from deductive databases (e.g., magic sets) to DL reasoning. It can also handle SWRL, F-Logic ontologies and SPARQL query answering, as well. Moreover, it provides a Java API in order to accommodate the management and the integration of different knowledge formalisms (e.g., OWL ontologies with SWRL rules). However, KAON2 does not support reasoning about nominals and cannot handle a large number of cardinality restrictions. Hence, it cannot deal with the full OWL-DL expressiveness.

dlvhex (Eiter, Ianni, Schindlauer, & Tompits, 2006b) is the name of a prototype application for computing the models of so-called HEX-programs, which are an extension of Answer Set Programs towards integration of external computation sources. dlvhex can communicate with OWL and RDF knowledge bases and can also return the results in RuleML syntax. A strong point of dlvhex is that it enables developers to write and embed plug-ins to the core engine. In fact, support for RDF and OWL is implemented through plug-ins too. Recently, another plug-in for querying HEX models through the SPARQL language (Polleres & Schindlauer, 2007). Through this plug-in dlvhex can be used as a query engine by providing a rewriter from SPARQL to rules. The source code and binaries of dlvhex are publicly available.

DR-DEVICE (Bassiliades, et al., 2006) is a defeasible logic reasoner for the Web based on the CLIPS expert system shell (CLIPS, 2008) that intends to integrate Semantic Web standards (RDF metadata, XML-syntax of rules) with non-monotonicity (e.g., strong negation). Specifically, it provides reasoning services over RDF metadata by taking advantage of rules defined by defeasible logic (strict rules, defeasible rules and defeaters). It also claims for reasoning efficiency compared to other systems based on logic programming.

Jess (Jess, 2008) is a Java framework for editing and applying rules, since it contains a scripting environment and a rule engine, as well. It supports a CLIPS-like language suitable for developing applications based on declarative rules (a.k.a. expert systems). Jess also uses an optimized version of Rete algorithm (Forgy, 1982) tailored for Java, comprising a very efficient rule engine. Recently, the evolution of rule technologies on the Web has led Jess to rebound its practical value in the community of Web developers. Moreover, the fact that Jess is a Java-based system facilitates its integration with a number of Web programming paradigms like Java servlets or applets. Finally, it supports backward-chaining and some additional features like procedural attachments.

Table 2 presents the types of inference support provided by the aforementioned reasoning

Table 2. Types of inference support by various reasoning engines

Inference Support Modules	TBox Reasoning	Abox Reasoning	Rules Reasoning
Jena2	Limited (incomplete RDFS/OWL reasoning)	Limited (incomplete RDFS/OWL reasoning)	JenaRules (forward/tabled backward chaining)
RacerPro	√	√	nRQL rules, first implementation of SWRL (forward chaining)
Pellet	√	√	DL-safe rules (SWRL subset)
Bossam	sound, incomplete	sound, incomplete	SWRL, Buchingae (forward chaining)
FACT++	√	sound, incomplete	-
KAON2	√ (except nominals)	√ (except nominals)	DL-safe rules (SWRL subset)
dlvhex	Limited, through interface with external reasoner	Limited, through interface with external reasoner	DL-Rules (non-monotonic logic program rules with queries to DL KB)
DR-DEVICE	-	-	Defeasible rules
Jess	Limited*	Limited*	SWRL*, Jess rules (forward/backward chaining)

* through appropriate transformations (Mei, Bontas & Lin, 2005; O'Connor et al., 2005)

modules. In (Cardoso, 2007), an analysis of the current trends and the adoption of available reasoning engines by the Semantic Web community are presented in detail.

4. EVALUATION OF EXISTING APPROACHES

In this section, a comparative study across the aforementioned methodologies for introducing rules in Web applications is presented. Firstly, we give some fundamental requirements that have to be satisfied by such formalisms. Afterwards, we compare various aspects from the perspectives of classical logic and logic programming, giving indicative examples. Finally, some experimental results that examine the efficiency of current efforts in the combination of ontologies with rules are presented.

4.1 Rule-Based Web Applications are Still "Web Applications"

Before evaluating the existing approaches to introducing rules in Web applications, we should identify the main requirements for such approaches. These requirements mainly stem from the nature of the Web itself and its current status. Firstly, WWW is a ubiquitous and massive multi-user distributed environment. In fact, this massive characteristic is its strong point, and is a direct consequence of its architectural and technological simplicity. Web technologies such as HTTP, HTML and XML are very simple to learn and use, even for plain users who are not IT experts. Such simplicity should be taken as granted for any Web-related technology, and this applies to rule systems as well. In this context, rules for the Web should be written and used even by users/developers not familiar with advanced knowledge engineering concepts. For example, negation is a rather advanced topic in logic-based systems (with Horn rules). Hence, the semantics of rules should be such that can be easily understood by naïve users. However, this would affect their expressiveness and would limit the inference power of rule-based systems that may be required by more demanding applications (i.e., Web service discovery engines). It is worthy to mention that most of the existing rule-based applications for the Web have adopted SWRL approach (see Section 3.1) in order to express rules. SWRL is neither a highly expressive language (e.g., no negation is available) nor a decidable one, but it remains simple.

Another requirement is that the rule-based systems for the Web are compatible with existing (Semantic) Web standards, such as XML, RDF, OWL and SAWSDL (Farrell & Lausen, 2007). This means that direct support for URIs or XML syntax should be available. On the other hand, writing rules in XML (e.g., like the SWRL and RuleML approaches propose) is a cumbersome task. This is indeed a difficult decision that has to be taken by the Web architects.

Furthermore, the addition of rules in Web applications requires their compatibility with existing forms of Web knowledge that have already attained a certain maturity level. Most of the knowledge bases developed in the context of Web are expressed in the form of ontologies (mainly written in OWL or RDFS). As a result, rules have to be integrated with ontologies properly.

4.2 Qualitative Comparison of Classical Logic and Logic Programming Approaches

The aforementioned knowledge representation methodologies (see Section 3.1) are either based on classical logic (e.g., DLs and SWRL) or logic programming (e.g., answer-set programming and defeasible rules). Across the literature, several differences between classical logic and logic programming paradigms have already been identified. In this section, we intend to survey and discuss these efforts by presenting the main incompatibilities that impede the reconciliation of the two approaches.

Monotonicity vs. Non-Monotonicity

Classical logic is based on standard model theoretic semantics and adheres to monotonicity of entailment. Informally, monotonicity means that the addition of new information to the knowledge base cannot invalidate conclusions inferred by current knowledge. As a result, classical logic is able to deal with incomplete information by nature.

Instead of classical logic, logic programming has non-monotonic features. It assumes complete knowledge and there is a unique model describing the state of the world. This way, addition of knowledge may reduce the inferences.

Unique Name Assumption

Another difference between the two paradigms is that logic programming approaches typically deploy the *Unique Name Assumption* (UNA). This assumption supposes that different names represent different objects of the world. This fact imposes severe limitations on the Web context, since several distinct URIs[4] may refer to the same content or data. On the contrary, in classical logic there is no one-to-one correspondence between the names and the objects of the domain. Hence, equality between individuals represented by different names can be derived. Although it imposes a huge computational cost, most of the current description logic reasoners support reasoning with equality.

Negation

Classical logic and logic programming face the aspect of negation from different perspectives. With respect to its monotonic nature, negation in classical logic allows inferring new information only if the truth or the falsehood of a statement is explicitly declared. This fact is related with the *Open World Assumption* (OWA) of classical logic theory where incompleteness of the knowledge base is considered.

On the other hand, *Negation-As-Failure* (NAF) adheres to the *Closed World Assumption* (CWA). Specifically, if a description is not known to be true, then the truth of the negated description is drawn. In that sense, absence of knowledge draws to negated knowledge and, thus, NAF has a non-monotonic behavior. Modeling the world according to CWA seems to be somewhat inappropriate for the Semantic Web. Since knowledge on the Web is not always available (e.g., web servers breakdowns), such an assumption could lead to incorrect inferences. However, the usefulness of different types of negation in rule-based Web applications is demonstrated in (Wagner, 2003; Alferes, Damasio, & Pereira, 2003).

Constraints and Restrictions

Another aspect where the classical paradigm differs from logic programming is on the treatment of *constraints* and *restrictions*. Regardless of the apparent similarity between constraints and restrictions, there are important differences between them.

Restrictions are used in the classical logic paradigm and they constitute part of the logical theory. By adding restrictions to a knowledge base, the knowledge statements are also increased and, thus, the inference of additional knowledge is permitted.

Restrictions may be further classified to the following main categories:

- *Value restrictions* or *range restrictions*. They are used to restrict the values of a property and possibly infer new information according to their type (a.k.a. range).
- *Cardinality restrictions.* They are used for restricting the number of values that an individual may have for a specific property. They can possibly infer the existence of new instances or equality between known individuals.

In terms of Description Logics, an example of cardinality restriction in the web service paradigm could be the following:

$$\text{Profile} \sqsubseteq \geq 1 \text{ hasInput} \qquad (6)$$

Such rule denotes that every service profile should have at least one input.

On the other hand, constraints (also called *integrity constraints*) are mainly used in deductive databases and logic programming in order to check if the knowledge base is consistent with a number of specified conditions. As a result, constraints cannot draw inference of new information, but they may lead to inconsistencies in the case that some conditions specified by them are violated inside the knowledge base. Usually, constraints are rules without head (i.e., they have a "false" value in their head), denoting that the conditions stated in the body should not be satisfied concurrently by the knowledge base.

Similarly to restrictions, constraints may be divided to:

- *Value constraints* or *range constraints*. Their importance consists in checking the type of a property value.
- *Cardinality constraints*. They are used for checking the number of values that an individual may have for a specific property.

Similarly to (6), a cardinality constraint could be written in logic programming as:

$$\leftarrow \text{Profile(s)} \wedge \neg\text{hasInput(s,i)} \qquad (7)$$

More details about integrity constraints and restrictions may be found in (de Bruijn, Polleres, Lara, & Fensel, 2005), where an alternative ontology language based on the logic programming subset of OWL is presented.

Other Differences

A number of additional differences between the described approaches have also been discussed in the literature. (Eiter et al., 2006a) raises the point of non-ground entailment in the logic programming approach, declaring that, since the semantics of logic programming is defined in terms of sets of ground facts, the inference of non-factual knowledge is not allowed. Contrary to the logic programming, classical logic permits the entailment of non-factual knowledge. Furthermore, decidability issues are explored in the combination of the two perspectives. In addition, (Pattel-Schneider, 2006) describes the treatment of datatypes by classical logic approaches (e.g., DLs) and logic programming. Moreover, it examines the role of tools that support each methodology and how they can facilitate the modeling of knowledge.

The aforementioned modeling paradigms have been proposed for formalizing rules on the Web. Concerning the advantages and the disadvantages of each approach, we believe that both perspectives are useful in the context of Semantic Web.

The open nature of the classical logic seems to be more suitable for formalizing such a distributed environment. By this mean, Semantic Web technologies based on classical logic accomplish the integration of information stemming from different sources. Knowledge becomes shareable in the sense that it can be accessed without any obligation to adopt a specific model or schema. Hence, data are available to everyone through WWW so as to be retrieved and used in applications appropriately.

On the other hand, logic programming makes several assumptions in order to simplify tasks like reasoning or modeling of the knowledge base. There are several useful features of logic programming like high expressiveness, negation-as-failure and decidability of reasoning. Moreover, many of the reasoning engines targeting at managing knowledge expressed in classical logic formalisms have been recently extended to support such features (e.g., Pellet, RacerPro, Bossam). Additionally, both users and developers are very familiar with the world of databases and logic programming languages like Prolog. It is worthy to mention that even SPARQL engines return “no” in ASK query patterns with no solutions. However, “don’t know” would fit better in an open environment where multiple solutions may exist outside the current knowledge base. This way, SPARQL takes advantage of the users’ familiarity with common databases, deciding not to complicate the query answering process.

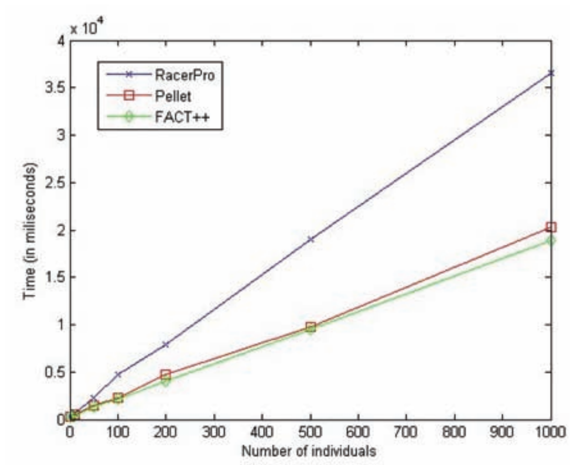
To summarize, last decade has shown to the developers of Web applications that different types of Semantic Web enabled applications requires different styles of modeling. As a result, the development of a framework that satisfy most of these needs seems to become unavoidable.

4.3 Quantitative Evaluation of Reasoning Modules

This section intends to quantify the total time required by popular reasoning modules in order to perform common reasoning tasks. Instead of (Pan, 2005; Gardiner, Horrocks, & Tsarkov, 2006), where the evaluation of description logic reasoners focuses on TBox reasoning tasks, here we examine both TBox and ABox reasoning as well as rules application. In particular, Figures 3 to 6 show the results of some indicative performance tests. These tests aim at demonstrating the efficiency of description logic reasoners and mainstream rule engines.

This quantitative evaluation involved the last stable versions of RacerPro (v1.9.0), Pellet (v1.5.1) and FACT++ (v1.1.11) description logic reasoners that were available for ontology reasoning as well as the Jess rule engine for SWRL rules application. Bossam was also tested as both ontol-

Figure 3. Evaluation of consistency check (TBox)



ogy reasoner and rule engine in this evaluation. However, Bossam's results are not displayed in the figures, since such a comparison would be improper. This stems from the fact that although Bossam constitutes a sound reasoning module it is not a complete reasoner for OWL. However, we should mention that Bossam performed well (i.e., it accomplished smaller execution times than the other OWL reasoners) handling small-size ontologies, while it threw out-of-memory errors when provided with large-scale ontologies (i.e., containing 500 and 1000 instances). Moreover, all reasoners were managed through Protégé OWL API in Java except Bossam which provides its own API. Finally, Jess was accessed via SWRL-Jess bridge (O'Connor et al., 2005).

The knowledge base used in these tests stems from the Web service description paradigm and it consists of a domain ontology and OWL-S service descriptions. The domain ontology, which represents the domain of football (i.e., player/team details and statistics), includes concepts described through necessary and sufficient conditions. The elements of this ontology are used for the

Figure 4. Evaluation of classification (TBox)

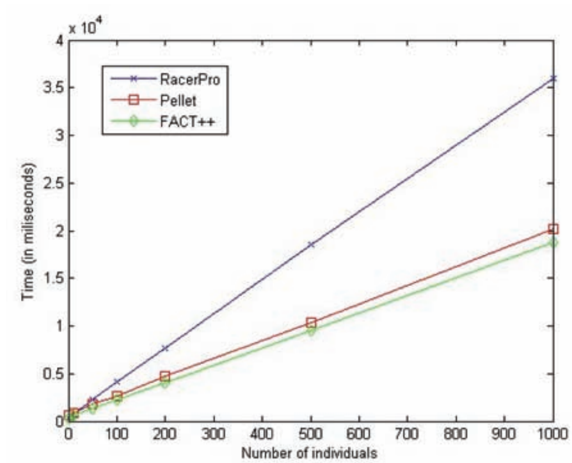


Figure 5. ABox reasoning evaluation (computation of inferred individual types)

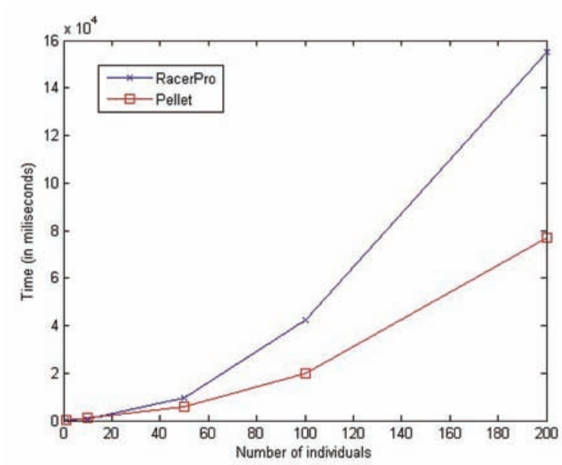
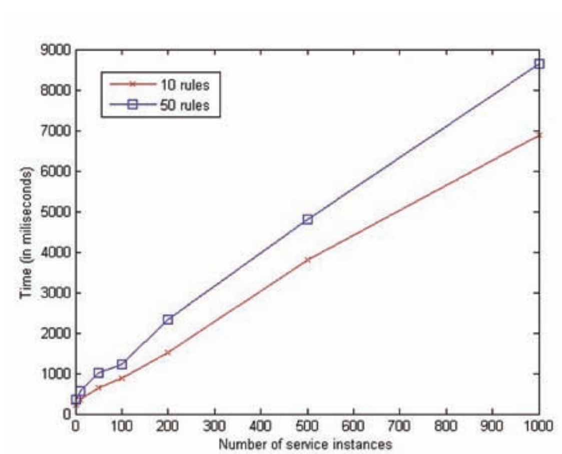


annotation of some Semantic Web services that provide search functionality to some underlying football statistics databases. Specifically, the service inputs and outputs are annotated through concepts of this domain ontology. The extract of the domain ontology used contains 37 concepts, 8 object properties and 3 datatype properties. Each service description involves 19 concept instances and 11 property instances.

Figure 3 depicts the performance of three description logic reasoners while checking the consistency of all classes over the aforementioned knowledge base. The execution times presented in this figure do not involve the time needed to load the models. The figure shows that these times increase as the number of instances contained in the knowledge base also increases. FACT++ and Pellet attained the best performance by achieving similar execution times. On the other hand, RacerPro performed worse than the others.

In Figure 4, the times required for classifying the hierarchy of the ontology are presented. Again, the times shown in the figure do not include the loading time of each model. The resulting perfor-

Figure 6. Jess performance executing SWRL rules



mances are very similar to those of the consistency checking process. FACT++ has slightly better performance than Pellet, while RacerPro has the worst performance again.

Figure 5 shows the efficiency of RacerPro and Pellet reasoners in realizing reasoning over ABoxes. In this figure we do not display FACT++, since it provides incomplete ABox reasoning. In particular, the experiment concerns the identification of the types (i.e., classes) that each individual belongs to. The figure shows that even the reasoning over an ontology containing 100 instances using Pellet (which seems to be the most efficient reasoner in this reasoning task) requires about 20 seconds. Moreover, both reasoners failed to compute inferred individual types for ontologies containing 500 and 1000 individuals.

It is worthy to mention that version 1.9.2 Beta of RacerPro was also available during the experiments. This version seemed to remain slower than FACT++ and Pellet in TBox reasoning tasks (consistency check and classification of hierarchy) while it performed better in ABox reasoning. However, the results are not displayed in the figures above, since this is not a stable version of the reasoner.

Figure 6 shows the time required by Jess rule engine to apply SWRL rules over ontologies containing various numbers of instances. These rules represent service composition constraints that should apply to the inputs and outputs of the services. We applied two different sets of rules to the previously described knowledge bases: the first set consisted of 10 rules while the second of 50 rules. In both cases, the execution time increases proportionally to the number of instances contained in the ontology. As expected, the delay imposed by the execution of rules was affected by the number of rules. However, the number of instances seems to affect execution times more than the number of rules. Hence, the inference process is complicated when real-time demands come up in distributed environments where applications have to support multiple individual instances.

To summarize, the time required to handle a large KB and execute reasoning in terms of Semantic Web technologies like DLs constitutes a limiting factor, even for the most efficient reasoners. This is a fundamental problem on the Web, since applications have to deal with a large number of instances representing data. Especially, when considering real time applications that call for small response times, the aforementioned results become unmanageable. This is the main reason why many researchers have recently focused on developing efficient and scalable reasoning applications over large individual sets. Instance Store (Horrocks, Li, Turi, & Bechhofer, 2004a) is such an approach that permits working in conjunction with any ontology reasoner that implements the DIG interface.

5. FUTURE TRENDS AND OPEN ISSUES

Several open issues that deserve further research efforts in the future have been identified throughout the chapter. Firstly, a Web standard for editing and embedding rules into Web applications should be specified. In our opinion, such a language should focus on its simplicity, instead of providing major expressiveness capabilities that will lead to a clumsy formalism. Rule Interchange Format (RIF) Working Group (RIF, 2008) works in this direction in order to produce W3C recommendations for enabling interchange of rules. Specifically, RIF does not intend to provide explicit mappings between various rule languages, but specify a mechanism capable of defining the meaning of the formulas of a rule language. This way, rules could be automatically translated across different formalisms.

Additionally, more tractable algorithms for Web-rules, TBox and ABox inference problems should be developed. These algorithms should be able to handle complex and heavy knowledge bases that combine rules and ontologies with a large number of concepts and relationships. Such knowledge bases are substantial, especially in the context of information integration where multiple domain vocabularies interact with upper-level ontologies. Furthermore, the Web is a large scale environment, where a huge set of resources are added every day. As a result, future knowledge bases will have to capture and describe more and more individuals. These facts should be taken into account by the developers that will target at designing new reasoning algorithms.

Finally, a more practical issue that should be investigated is the development of a unified reasoning framework capable of managing both ontologies and rules. Today, there is no efficient and easy-to-use integrated reasoning module that can reason over both formalisms. As a consequence, the developer should use at least two different reasoning modules to handle such an integrated knowledge base. This can result to unexpected situations. For example, the restrictions defined by the ontology can be violated by the application of rules, since the rule engines do not take into account these restrictions (e.g., disjointness of concepts). Similarly, the application of rules could produce knowledge that would be useful for further description logic inferences.

6. CONCLUSION

In this chapter we have discussed the application of rules to Web applications in order to achieve intelligent application behavior and efficient management of knowledge. We have described the main methodologies and technologies for integrating rules with ontologies, since the latter constitutes a mature knowledge technology on the Web. The chapter has also examined aspects of the different approaches. We also showed through several experiments that current reasoning modules are not efficient enough to manage knowledge stemming from large-scale environments like the Web, especially in the context of real-time applications which impose severe constraints in response times. Finally, more improvements should be made in the standardization of rules formalism on the Web and in the development of reasoning modules that can handle and reason over both ontologies and rules as integral knowledge.

KEY TERMS AND DEFINITIONS

Logic Programming: It is a declarative paradigm of programming that is mainly based on first-order logic. Prolog is the most common logic programming language.

Knowledge-Based System: A system that exploits knowledge representation and reasoning techniques in order to achieve an intelligent behavior.

Knowledge Representation: It is the process of exploiting formal methodologies and languages (e.g., rules formalisms, ontologies) in order to capture and describe knowledge.

Ontology: A formal representation of a domain of discourse that describes concepts and relationships among them. This way, it provides a common vocabulary and allows for the inference of new knowledge.

Reasoning: The systematic process of inferring new knowledge by applying formal implication rules to a given knowledge base.

Rule-Based Application: An application that takes advantage of rules formalisms (e.g., Horn-clauses) in order to represent and infer new knowledge.

Semantic Web: It is an extension of the current Web where resources are described through formal syntax and semantics in order to be human- and machine-readable.

ABSTRACT

The development process of Web services needs to focus on the modeling of business processes rather than on low-level implementation details of Web services, and yet it also needs to incorporate the support for frequent business changes. This chapter presents the UML-based Rule Language (URML) and REWERSE Rule Markup Language (R2ML), which use reaction rules (also known as Event-Condition-Action rules) for modeling Web services in terms of message exchange patterns. Web services that are being modeled in this way can easily be integrated in the wider context of modeling orchestration and choreography. In order to achieve proposed solution, we have developed a plug-in for the Fujaba UML tool (so called Strelka) and a number of model transformations for round-trip engineering between Web services and reaction rules. Also, the paper presents mappings of models of Web services with reaction rules into the Drools rule language, thus enabling the run time execution semantics for our rule-based models.

DOI: 10.4018/978-1-60566-402-6.ch018

1. INTRODUCTION

Web services provide a communication interface and a workflow management protocol for business systems. Their goal is set to change the Web from a static collection of information, to a dynamic place where different software components (business logics) can be easily integrated (Arroyo et al., 2004). Some of the factors that constrain web services from achieving that goal can be named as follow: when developers try to enrich the existing Web services with some new functionality, they have to implement necessary changes manually, which may lead to potential execution errors; furthermore, business rules, due to their declarative nature, are used for reflecting dynamic changes representing desired alteration in the business process. When business rules are used in a networked business, they are often large and complex, which makes them difficult to manage and change. There is a lack of automatic mechanism for updating Web services based on the business rules changes (Ribaric et al., 2008).

The need for a more straightforward way to express, and manage business rules as a separate part of Web services' composition has been recognized by researchers for the numerous benefits that it provides (Charfi & Mezini, 2004). However, integrating rule-based systems in a service-oriented environment is a complex task, due to the fact that both worlds have their own paradigms (Rosenberg & Dustdar, 2005). Many different factors involve in this integration. However, the most important one of these factors is the architecture of service oriented systems. In this architecture, layers play a great role. The layering architecture is needed to be represented and deployed in the world of rules which become challenging and could not be simple done. This integration approach should be loosely coupled, meaning that it is reasonable to expose business rules as services. The way of modeling Web services presented in this paper facilitates this integration process, and those services can be more easily integrated in the wider context of modeling orchestration and choreography.

A promising way to solve these problems is to use a high-level modeling approach combined with the use of rules. A modeling approach will allow developers to focus on a problem domain rather than on an implementation technology. This is why we propose using an approach based on Model Driving Engineering (MDE). Although, there have been several attempts to leverage MDE principles to model Web services, they are still very low level oriented, as they again focus on technical details covered either by WSDL (Bezivin et al., 2004) (Vara et al., 2005) or OWL-S (Timm & Gannod, 2005) (Gronmo et al., 2005). The use of rules implying that they are defined in a declarative way, they can dynamically reflect business logic changes at run-time without the need to redesign the whole system. Since Web services are used for integration of business processes of various stakeholders, it is important for them to reflect changes in business logic, or policies, as good as possible.

The solution that we propose is to use rules to represent and model business processes from the perspective of message exchange. That is, our modeling approach enables one to model Web services from the perspective of the underlying business logic regulating *how* Web services are used regardless of the context *where* they are used. To do so, our proposal is to leverage message-exchange patterns (MEPs) as an underlying perspective integrated into a Web service modeling language. This perspective has already been recognized by Web service standards (Chinnici et al., 2007), and our contribution is to raise this to the level of models.

As the leading Rule Modeling language we benefit from UML-based Rule Modeling Language (URML) (Lukichev & Wagner, 2006a) for our approach. URML having strong ties with R2ML (REWERSE Rule Markup Language) empowers us to model rules in various languages.

URML supports modeling of domain vocabularies in addition to integrity, derivation, production and reaction rules. .Business rules, being similar to natural language rules, are proposed to be modeled by using reaction rules (also known as Event-Condition-Action, ECA, rules) in this paper. Reaction rules will perform a task (Action) under some circumstances (Conditions) if some events (Event) take place and can best describe a business rule.

We also have developed a plugin (called Strelka) for the well known UML tool Fujaba, which has a support for URML notation. Strelka also has the support transformation of URML models into Web Service Description Language (WSDL) and different types of rule languages such as Drools, Jess, and SWRL. In this paper, we discuss those transformations that are implemented by using a model transformation language entitled the ATLAS Transformation Language (ATL) (ATL, ver. 0.7).

The paper is structured as follows: in the next section we give a bit of the background, including, Web services, R2ML and URML languages with the emphasis on reaction rules. In section 3 we introduce our approach for modeling business rules and services following by section 4 in which we introduce Strelka (Lukichev & Wagner, 2006b), a tool we developed that is capable of presenting URML diagrams, and performing transformations. Section 5 describes mapping process between URML and WSDL that is a part of Strelka, and also covers a deployment of URML diagrams to the Drools rule engine. Section 6 summarized the related work done so far and in Section 7 we conclude this work by summarizing the major points.

2. BACKGROUND

In this section, we give a brief overview of the technologies and techniques relevant to the problem under study. This includes a short description of Web services, Drools rule engine, and rule language definitions based on MDE principles used in our modeling approach. A complete introduction into the ATLAS Transformation Language (ATL) can be found in the chapter entitled “Sharing ontologies and rules using model transformations”.

Web Services

A Web service is a loosely coupled component that exposes functionality to a client over the Internet (or an intranet) by using web standards such as HTTP, XML, SOAP, WSDL, and UDDI (Timm & Gannod, 2005).

SOAP is an XML-based protocol for exchanging information in a decentralized, distributed environment. SOAP builds on XML and common Web protocols (HTTP, FTP, and SMTP) (Coyle, 2002). A SOAP message is the basic unit of communication between SOAP nodes. The “envelope” element represents the root of a SOAP message structure. It contains a mandatory body construct and optional header construct (Gudgin et al., 2007). The header construct is where meta-information can be hosted. In a large number of service-oriented architectures, the header is an important part of the overall architecture, and although it is optional it is rarely omitted.

Web Service Description Language (WSDL) is a language for describing both the abstract functionality of a service and the concrete details of a Web service (Chinnici et al., 2007). At an abstract level, WSDL describes a Web service in terms of interfaces and the operations supported by the interfaces. An operation is an interaction with the service consisting of a set of (input, output, infault and outfault) messages exchanged between the service and other parties involved in the interaction (Chinnici et al., 2007). The messages are described independently of a specific wire format by using a type system, typically XML Schema. WSDL also describes the point of contact for a service provider, known as the endpoint – it provides a formal definition of the endpoint interface and also establishes the physical location (address) of the service.

Potential requestors need a way to discover Web services descriptors. It is necessary that these descriptors are collected and stored in a central registry. The key part of the Universal Description Discovery and Integration (UDDI) specification (Clement et al., 2004) presents standardizing information inside such a registry as well as specifying the way the information can be searched and updated.

Regardless of how complex tasks performed by a Web service are, almost all of them require the exchange of multiple messages (Erl, 2005). It is important to coordinate these messages in a particular sequence, so that the individual actions performed by the message are executed properly. Message exchange patterns (MEPs) are a set of templates that provide a group of already mapped out sequences for the exchange of messages (Erl, 2005). This basically means that MEPs define how services should be used, as they can coordinate input and output messages related to a certain operation.

The WSDL 2.0 specification defines three MEPs:

- in-only pattern – supports a standard fire-and-forget pattern (i.e., only one message is exchanged);
- robust in-only pattern – presents a variation of the in-only pattern that provides an option of sending a fault massage, as a result of possible errors generated while transmitting, or processing data;
- in-out pattern – presents a request-response pattern where two messages (input and output) must be exchanged.

However, WSDL 2.0 specification offers the possible use of five more patterns (Lewis, 2007):

- out-in pattern – also consists of exactly two messages (like in-out pattern), but now a service provider is the one that initiates the exchange of messages;
- out-only – consists of exactly one message (like in-only pattern), and is most often used for message notification;
- robust out-only - presents a variation of the out-only pattern that provides an option of sending a fault massage;
- in-optional-out – is similar to pattern in-out with one exception: sending an message that represents a response is optional, and because of this a requester that has started a communication should not expect this message;
- out-optional-in – is opposite to the previous pattern, where the input message is optional.

Drools

Drools is a business rule management system (BRMS) with a forward chaining inference based rule engine, more correctly known as a production rule system, using an enhanced implementation of the Rete algorithm. BRMS is a production rule system with a focus on knowledge representation to express propositional and first order logic in a concise, non ambiguous and declarative manner. The core of a production rules system is an inference engine that is able to scale to a large number of rules and facts. The inference engine matches facts and data, against production rules, also called productions, to infer conclusions which result in actions. A production rule is a two-part structure using first order logic for knowledge representation (Proctor et al). Figure 1 presents a schema of a production rule. It executes the actions while the conditions are being satisfied. Drools representation contains the same structure, LHS (Left Hand Side) is referring to conditions while RHS (Right Hand Side) is referring to actions. Name of the rule which is presented by “name”

Figure 1. First order logic representation (left) - Drools representation (right)

```
when
    <conditions>
then
    <actions>
```

```
rule "name"
        attributes
        when
                LHS
        then
                RHS
end
```

is just for better understanding of rules and have no functional value. Attributes, marked with attributes in the rule are used for the rule internal functionality itself.

The process of matching new or existing facts against production rules is called *pattern matching*, which is performed by the inference engine (part of Drools). Drools implements and extends the Rete algorithm The Drools Rete implementation is called ReteOO, signifying that Drools has an enhanced and optimized implementation of the Rete algorithm for object oriented systems (Schneier). For better understanding of rules and their structure please refer to the chapter "Object Oriented Rule Languages".

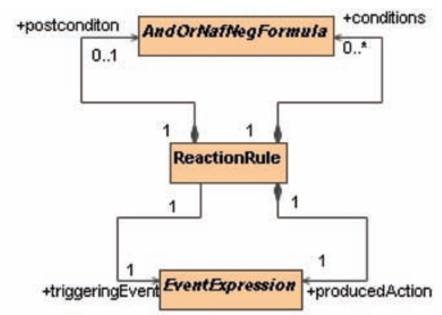
R2ML

Existing Web rule languages (RuleML (Hirtle et al., 2006) and SWRL (Horrocks et al., 2004)) and rule modeling approaches (SBVR (SBVR, 2006) and PRR (Charfi & Mezini, 2004)) very nicely serve the purpose of rule interchange and rule representation independent of any specific platform, respectively. However, none of these languages offers a suitable modeling foundation that can be used for modeling Web services from a more abstract perspective of business processes and business rules in which they are used. That is, the language should be able to model reaction rules. Yet, such a modeling language should be closely related to the already existing software modeling languages such as UML and preferably defined by following MDE principles. Finally, the language should be closely related to the Web standards for defining ontologies (OWL) and rules (RIF).

We have decided to use REWERSE I1 Rule Markup Language (R2ML), as it fully satisfies the above requirements. The language is defined by a MOF-based metamodel which is refined by OCL constraints that precisely define relations between the language's constructs in addition to those defined by the metamodel; it has an XML schema defined concrete syntax; it has a UML-based graphical concrete syntax, so called UML-based Rule Modeling Language (URML), which we will introduce it in the section below; and it has a number of transformations with other rule languages (e.g., JBoss' Drools and OCL) allowing us to translate Web service models to the rule-based languages that can then regulate the use of Web services.

R2ML is a rule language that addresses all the requests defined by the W3C working group for the standard rule interchange format (Ginsberg et al., 2006). The R2ML language can represent different types of rule constructs, that is, it can represent different types of rules (Wagner et al., 2006) including: integrity rules, derivation rules, production rule, and reaction rules. Integrity rules in R2ML, also known as (integrity) constraints, consist of a constraint assertion, which is a sentence in a logical language such as first-order predicate logic or OCL. Derivation rules in R2ML are used to derive new knowledge (conclusion) if a condition holds. Production rules in R2ML produce actions if the conditions hold, while post-conditions must also hold after the execution of actions. A reaction rule is a statement of programming logic (Giurca et al., 2006) that specifies the execution of one or more actions in the case of a triggering event occurrence and if rule conditions are satisfied. Optionally, after the execution of the action(s), post-conditions may be made true. R2ML also allows one to define vocabularies by using the

Figure 2. Definition of reaction rules in the R2ML metamodel

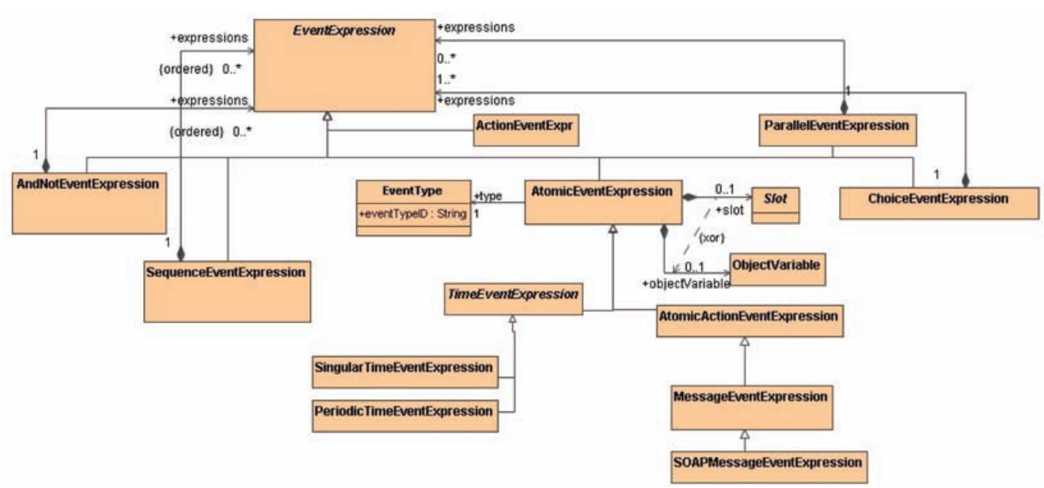


following constructs: basic content vocabulary, functional content vocabulary, and relational content vocabulary. Here we give short description of vocabulary constructs that we use in this paper. Vocabulary is a concept (class) that can have one or more VocabularyEntry concepts. VocabularyEntry is abstract concept (class) that is used for representing other concepts by its specialization. For example, one of the VocabularyEntry-s is an R2ML Class concept which represents the class element similar to the notion of the UML Class. An R2ML Class can have attributes (class Attribute), reference properties (class ReferenceProperty) and operations (class Operation).

Due to the importance for our Web service modeling approach, here we only describe the details of R2ML reaction rules. Reaction rules represent a flexible way for specifying control flows, as well as for integrating events/actions from a real life (Giurca et al., 2006). Reaction rules are represented in the R2ML metamodel as it is shown in Figure 2: triggeringEvent is an R2ML EventExpression (Fig. 4); conditions are represented as a collection of quantifier free logical formulas; producedAction is an R2ML EventExpression and represents a system state change; and (optional) postcondition must hold when the system state changes.

The R2ML event metamodel defines basic concepts that are needed for dynamic rule behavior (Figure 3). There are two types of events: atomic event (AtomicEventExpression) and composite events (AndNotEventExpression, SequenceEventExpression, ParallelEventExpression or ChoiceEventExpression). Characteristic of an atomic event is that it has no duration (duration = 0). For the sake of modeling Web services, we are using MessageEventExpression for both triggering events and produced actions. MessageEventExpression is used for modeling messages that are part of the definition of Web services, including, input, output, in-fault, and out-fault messages. Each MessageEventExpression has its

Figure 3. Event expressions in the R2ML metamodel



own type – EventType. In terms of WSDL, message types are defined by XML Schema complex types, while in R2ML, EventType is a subclass of Class (already defined as a part of the R2ML Vocabulary). This means that each EventType has its own attributes, associations, and all other features of R2ML classes.

URML

UML-Based Rule Modeling Language (URML) is a graphical concrete syntax of R2ML. URML is developed as an extension of the UML metamodel to be used for rule modeling. In URML, modeling vocabularies is done by using UML class models. Rules are defined on top of such models. The URML reaction rules metamodel, which we use for modeling services, is shown in Figure 4a. The figure shows components of a reaction rule: Condition, Postcondition, RuleAction and EventCondition. The figure also shows that reaction rules are contained inside the UML package which represents Web services operation. This means, that such packages have a stereotype <<operation>> in UML diagrams. An instance of the EventCondition class is represented on the URML diagram as incoming arrow (e.g., see Figure 5), from a UML class that represents either an input message or an input fault message of the Web service operations, to the circle that represents the reaction rule. The UML class that represents the input message (input-Message in Figure 4b of the Web service operation is MessageEventType (a subclass of EventType from Figure 3) and it is represented by using the <<message event type>> stereotype on UML classes. The UML class that represents the input fault message (inFault in Figure 4b) of the Web service operation is FaultMessageEventType in the URML metamodel. In URML diagrams, FaultMessageEventType is represented by the <<fault message event type>> stereotype on UML classes. EventCondition contains an object variable (ObjectVariable in Figure 4c), which is a placeholder for an instance of the MessageEventType class. The object variable has a name that corresponds to the arrow annotation, which represents EventConditon.

An instance of the RuleAction class is represented as an outgoing arrow on the URML diagram, from the circle that represents the reaction rule to the class that represents either an output message or an output fault message of the Web service operation. The UML class that represents the output message (outputMessage in Figure 4c) of the Web service operation is MessageEventType and it is represented with the <<message event type>> stereotype on UML classes. The UML class that represents the output fault message (outFault) of the Web service operation is FaultMessageEventType in the URML metamodel and it is represented with the <<fault message event type>> stereotype on UML classes. RuleAction contains an object

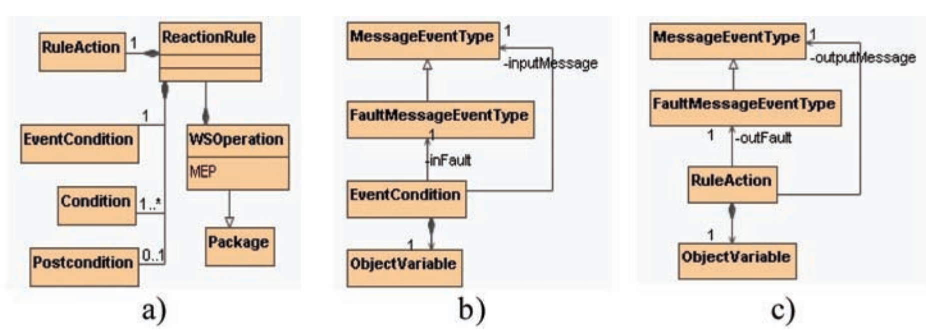

Figure 5. PIM level of the in-out message exchange pattern with out-fault, presented in URML

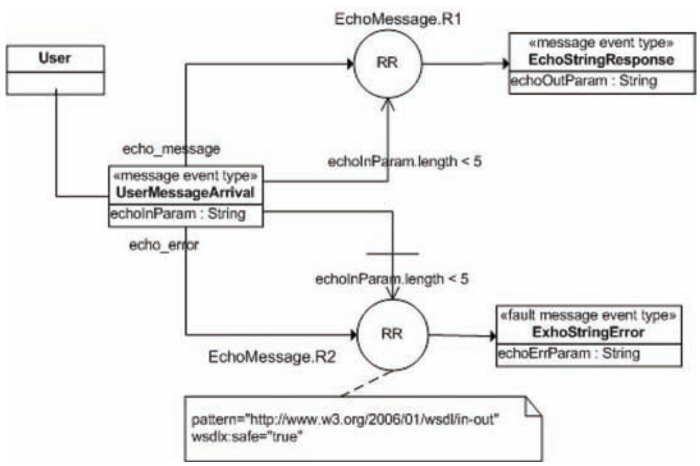


variable (ObjectVariable), which represents an instance of the MessageEventType class.

3. MODELING

In this section the idea behind modeling of rules and business processes will be exposed. Modeling will be performed with the help of URML and R2ML. In section 5 with the use of modeling, the transformation to the web services and automatic generation of codes will be described.

Rule Modeling

As stated, in this paper we are concerned with reaction rules. Reaction rule formalizes event-condition-action behavioral model, where the action is executed on event with a condition satisfied. Let us analyze the following example: *On customer book item request, if the item is available, then approve order and decrease amount of items in stock.* In this rule *on customer book item request* is a triggering rule event, *if the item is available* is a rule condition, *approve order* is a rule action and *decrease amount of items in stock* is a postcondition, which can be expressed as a logical constraint, requiring less amount of items in stock, than before the rule execution.

There are several general advantages of using reaction rules for specifying web services:

- Requirements are often captured in the form of rules in a natural language, formulated by business people;
- Reaction rules are easier to maintain and integrate with other kinds of rules, used in business applications (integrity rules, which specify constraints the data must fulfill, derivation rules, which explain how a model element can be derived);
- The topic of rules validation and verification is well studied;
- Reaction rules emphasis on events gives a flexible way to specify control flow and web service interaction patterns.

Our approach is on the edge of the MDE, Web Services, and rules. It brings several large communities together and helps to facilitate the use of rules and MDE technologies in the growing area of Web Services.

Business Rule Modeling

In this section we describe the concept of our approach talking about modeling of Business rules with the help of web services. In our approach, we look from the perspective of the potential patterns of the use of services. That is, we model services from the perspective of MEPs. It is important to point out that we **first start from the definition of a business rule that corresponds to a MEP under study**, but without considering the Web services that might be developed to support that rule. In this way, unlike other approaches to modeling of Web services, we are focused on the business rules describing how particular services are used, but without explicitly stating that we are talking about Web services. This approach enables us, not only to focus on the problems under study and the underlying business logic regulating the use of Web services, but also now we are able to translate such Web service modeling to both Web service languages and rule-based languages that can regulate how services are used at run-time.

Here, we describe how the in-out MEP is modeled in URML. The *in-out* MEP consists of exactly two messages: when a service receives an input message, it has to reply with an output message. This means that a fault message must be delivered to the same target node as the message it replaces, unless otherwise specified by an extension or binding extension. To show how this variation of the in-out MEP can be modeled by using reaction rules, we start our discussion from an example of the in-out MEP with an out-fault message. Let us consider the following business rule: *When a user sends a message, if the length of the message is less than five characters long return the message to the user, otherwise return an error message.*

The business rule is an in-out MEP and can be represented by two reaction rules, represented in semi-formal pseudo rule syntax:

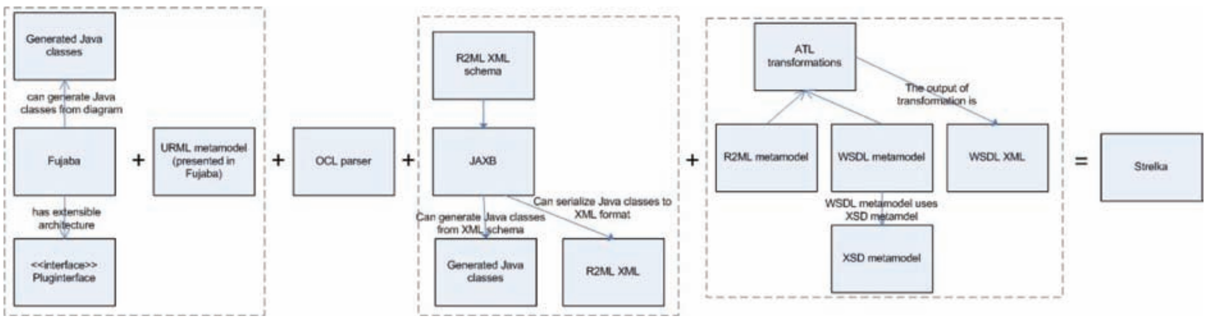
```
ON UserMessageArrival (echoIn-
Param)
IF echoInParam.length < 5 THEN
DO EchoStringResponse (echoIn-
Param)
ON UserMessageArrival (echoIn-
Param)
IF NOT echoInParam.length < 5
THEN
DO EchoStringError (“message too
long”)
```

In order to have these rules represented using our modeling notation, and also to be able to relate the rules with the elements of vocabularies, we model these rules by using URML. It is important to stress that all rules-based systems define business rules on top of business vocabularies. Thus, the URML graphical notation enables us to define business rules regulating the use of Web services by leveraging a human-comprehendible, and yet formally consistent representation, with the underlying business vocabularies (i.e., UML class models). These abovementioned two reaction rules represented in URML are shown in Figure 5.

In this particular case, we have the following situation: triggering event of either rule (i.e., UserMessageArrival) maps to the input message of the Web service operation. The action of the first reaction rule (i.e., EchoStringResponse), which is triggered when a condition is true, maps to the output message of the Web service operation. The action of the second reaction rule (i.e., EchoStringError), triggered on a false condition, maps to the out-fault message of the Web service operation.

As shown, a web service operation may be modeled by using more than one rule, where rules, that define an operation, are grouped in one package by the name of the operation. Otherwise, for modeling the basic in-out MEP, only one (first) reaction rule would be used. Besides the classes that model exchanged messages, the URML diagrams also

Figure 6. Strelka's functionality



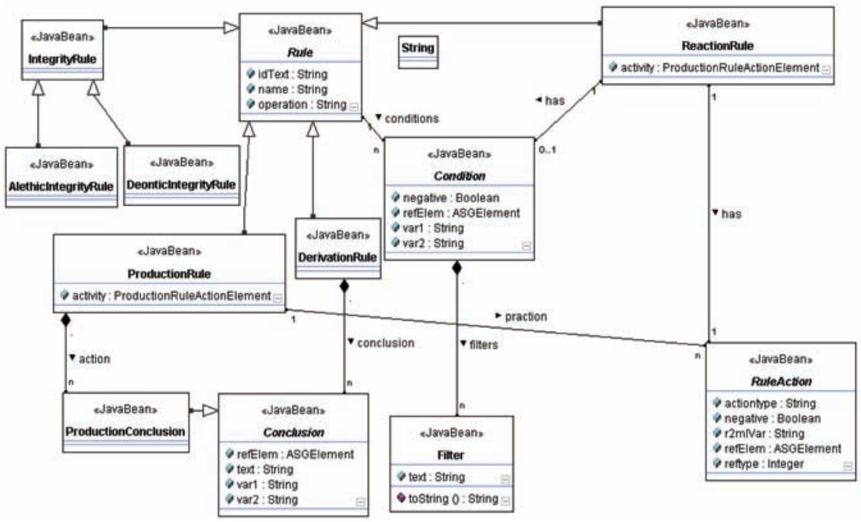
model conditions (e.g., echoInParam.length < 5). Such condition constructs are modeled by using OCL filters. OCL filters are based on a part of OCL that models logical expressions, which can be later translated to R2ML logical formulas, as parts of reaction rules. However, these OCL filters cannot be later translated to Web service descriptions (e.g., WSDL), as those languages cannot support such constructs. But, we can translate our URML models into rule-based languages (e.g., Jess or Drools). This means that for each Web service, we can generate a complementary rule, which fully regulates how the service is used. Another benefit of this approach is that our generated Web services, and their regulating rules, are consistent, as they originate (i.e. they are generated from) the same rule-based Web service model.

4. STRELKA: OUR MODELING ENVIRONMENT

In this section, we describe Strelka – a tool that was implemented as a plugin for the Fujaba tool[1]. Fujaba is a UML modeling tool, developed at the University of Paderborn in Germany. Fujaba allows creation of different types of UML diagrams. It allows generation of Java code based on created model, and it offers a plugin interface that we used for Strelka implementation. Figure 6 shows, symbolically, the architecture of Strelka, as well as the functionality that it provides.

The first part of Figure 6 (leftmost dashed box) shows us two important features Fujaba has: it is capable of generating Java code from diagrams, and it offers easily extensible architecture suitable for plugin implementation. This box also symbolically shows that one of the steps that need to be undertaken when creating a plugin for Fujaba is to create a metamodel for the new elements Fujaba will be extended with. After this first box, in the figure, we have an OCL parser. The OCL parser, which we used in this version of Strelka, is developed at the Technical University of Dresden in Germany[2]. This parser is widely accepted open source tool – besides Fujaba, it can be also integrated into other tools: ArgoUML, Borland Together, Poseidon. The second dashed box on Figure 6 shows that we use JAXB in the process of mapping URML to R2ML. JAXB guaranties that the R2ML XML document we get as the result of serialization of URML diagram created in Strelka, is valid according to the R2ML XML schema. The reason we use JAXB, is that Fujaba does not have explicitly defined metamodel in some of the metamodeling languages (e.g. MOF, or Ecore). So, we could not use model transformations (and ATL), in the mapping process between URML and R2ML like we did in the process of mapping between R2ML and WSDL (this mapping we describe in the next section). And the last dashed box on Figure 6 shows that Strelka has an integrated support for calling model transformations between R2ML and WSDL.

Figure 7. Strelka's rule metamodel



As already mentioned, one of the steps in the process of creating plug-ins for Fujaba is defining a metamodel for all the new elements that we extend Fujaba with. This metamodel is created in Fujaba, and then Java code is generated from it. This Java code we use afterwards, in the process of generating plugin itself. As the process of defining metamodel, and Java code generation is complete, we can create class diagrams that can incorporate those newly created elements, as well as UML elements that were already available (e.g. classes and associations). Figure 7 presents fragment of the Rule metamodel created in Fujaba. Classes that are relevant to the modeling of reaction rules are: ReactionRule, MessageAction, EventCondition, MessageEventType, and FaultMessageEventType. Figure 7 shows relations between the ReactionRule class to the other classes in this metamodel. The ReactionRule class is a subclass of Rule class (just like IntegrityRule, ProductionRule, and DerivationRule classes, which are used for modeling integrity, production, and derivation rules respectively).

5. TRANSFORMING WEB SERVICE MODELS

In this section, we summarize the translation process from URML reaction rules to Web services, and then we describe how this URML model can be transformed to Drools rule language.

The process of getting WSDL documents from URML models is as follows: first, we create an URML diagram in Strelka, after this we serialize it in the R2ML XML concrete syntax (this functionality is built in Strelka, and it relies on the use of JAXB). Once URML reaction rules are serialized to R2ML XML, they are translated into WDSL documents (this translation is done at the level of metamodels as described below). It is important to say that this process allows for two way transformation between URML and WSDL, that is, it is possible to perform reverse engineering of existing services, and extract business rules already integrated to service implementation.

To support this approach, we have implemented a number of transformations between different languages and their representations (these transformations can be found on the ATL ZOO page (WSDL2R2ML, 2006):

- *URML and R2ML XML concrete syntax*. As previously stated, this is the only transformation that is not implemented by using ATL (ATL, ver. 0.7), but instead it is based on JAXB
- *R2ML XML-based concrete syntax and R2ML metamodel*. This transformation is important to bridge concrete (XML) and abstract (MOF) syntax of R2ML. This is done by using ATL and by leveraging ATL's XML injector and extractor.
- *R2ML metamodel and WSDL metamodel*. This transformation is the core of our solution and presents mappings between R2ML and WSDL at the level of their abstract syntax.
- *WSDL XML-based concrete syntax and WSDL metamodel*. This transformation is important to bridge concrete (XML) and abstract (MOF) syntax of WSDL. This is done by using ATL and by leveraging ATL's XML injector and extractor.

Here, we describe the third and the forth transformation: i.e. transformation between R2ML metamodel and WSDL metamodel, and transformation between WSDL XML schema and WSDL metamodel.

Transformation Between WSDL Metamodel and R2ML Metamodel

Figure 8 shows the general principle of mappings between WSDL metamodel and R2ML metamodel (as can be seen on the figure, these mappings can be done in both directions).

Process of transforming WSDL metamodel elements to R2ML metamodel elements is conducted in the MOF technical space (TS) (Kurtev et al., 2002). Table 1 shows a conceptual mapping between these metamodels (this table does not show parts related to the mapping between the XML Schema language, which WSDL uses for defining message types and vocabularies, and the R2ML vocabulary).

Figure 9 shows an example of a matched rule from our (WSDL2R2ML.atl) transformation (for the Input class in the WSDL metamodel), and Figure 10 shows a graphical presentation of this mapping (for this particular class) between WSDL and R2ML metamodel. This matched rule initializes "sender", "objectVariable" and "type" features of the target R2ML MessageEventExpression element (we are putting a string "to_be_defined" in the "sender" feature, as the user will provide this information if required. This feature refers to the requester of the service).

As the result of the execution of WSDL2R2ML.atl transformation, we get an R2ML model. This model (which is an instance of the R2ML metamodel) can later be serialized into the R2ML XML concrete syntax, by our R2ML2XML.atl transformation and the use of the XMLExtractor class.

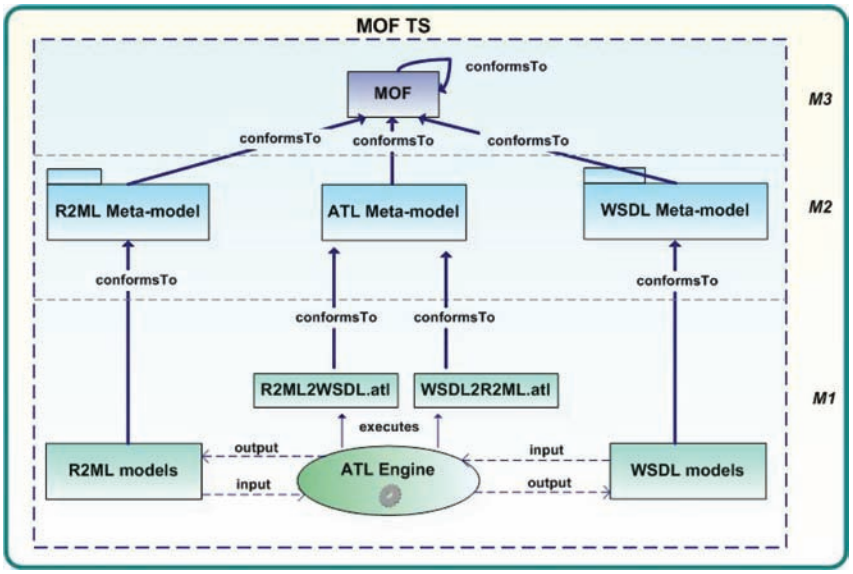
The WSDL2R2ML.atl transformation is defined as a sequence of ATL rules and ATL helpers. It has 11 matched rules, 3 lazy rules and 3 helpers.

Transformation, in the opposite direction, from R2ML metamodel elements to WSDL metamodel elements (R2ML2WSDL.atl) is based on the same conceptual mappings presented in the Table 1. This transformation uses 9 matched rules, 4 lazy rules, 1 unique lazy rule and 5 helpers. Figure 11 shows one matched rule from R2ML2WSDL transformation. This rule is mapping R2ML ReactionRuleSet element into WSDL Service and Interface elements.

Transformation of WSDL XML Schema to WSDL Metamodel

Because the concrete syntax of WSDL is defined in the XML technical space, and its abstract syntax (metamodel) is defined in the MOF TS, it is necessary to make a translation from concrete syntax

Figure 8. Mappings between models that conform to WSDL metamodel to models that conform to R2ML metamodel



elements to the abstract syntax elements. For this translation we have used XML metamodel (XML metamodel, 2006) as a bridge between XML and MOF TS.

To transform an XML document from XML TS to the XML model (instance of a XML metamodel) of the same rule in the MOF TS, we have used the XMLInjector class. By using a SAX parser, this class creates an XML model from an XML file. The next figure (Figure 12) shows general principle of mapping between WSDL XML concrete syntax and WSDL abstract syntax. Figure shows that the transformation can be done in both directions (i.e. we created bidirectional transformations).

Before we describe transformation process between WSDL XML schema and WSDL metamodel, we stress a fact that because WSDL does not define its own language for defining data types, we are referring to the XSD metamodel that can be obtained from the Eclipse Model Development Tool project[3].

Table 1. An excerpt of the mapping between the WSDL metamodel and the R2ML metamodel

WSDL metamodel	R2ML metamodel
Description	RuleBase
ElementType	Vocabulary
Interface	ReactionRuleSet
Operation	ReactionRule
Input	MessageEventExpression
Infault	MessageEventExpression
Output	MessageEventExpression
Outfault	MessageEventExpression

Figure 9. ATL matched rule that transforms WSDL Input element to R2ML MessageExpression element

```
rule TriggeringEvent {
  from i : WSDL!Input (
     i.oclIsTypeOf(WSDL!Input)
  )
  to o : R2ML!MessageEventExpression (
     sender <- 'to_be_defined',
     objectVariable <- thisModule.ObjectVariable(i.element),
     type <- i.element
  )
}
```

Transformation from WSDL XML schema to the WSDL metamodel has two primary steps:

- **Step 1:** This step is about transforming WSDL document from XML TS into MOF TS. In this step WSDL document (EchoService.xml on the Figure 12) is transformed into the WSDL metamodel that represents abstract syntax of the WSDL language in the MOF TS. By using XMLInjector class, WSDL XML document is transformed into model that conforms to the MOF based XML metamodel (step 1 on the Figure 12). As the result of this process we get XML model that can be presented in the XML XMI format (step 2 on the Figure 12).
- **Step 2:** This step is about transforming XML model (EchoService_XML on the Figure 12) into the WSDL based model (EchoService_WSDL on the Figure 12). ATL transformation XML2WSDL.atl (step 3 on the Figure 12) is performing this mapping. The output WSDL model (EchoService_WSDL) conforms to the WSDL metamodel. The XML2WSDL.atl transformation is executed on the model level (M1 level), by using information

Figure 10. Graphical presentation o mapping shown on the Figure 9

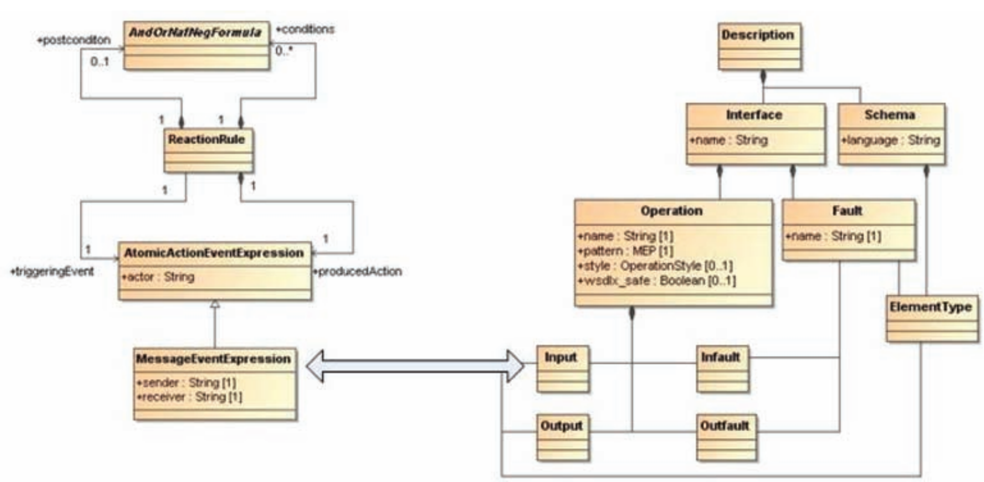


Figure 11. ATL matched rule that transforms R2ML ReactionRuleSet element to WSDL Interface element

```
rule Interface {
  from i : R2ML!ReactionRuleSet (
    i.oclIsTypeOf(R2ML!ReactionRuleSet)
  )

  to serv : WSDL!Service (
    name <- i.ruleSetID,
    interface <- inter,

    endpoint <- en
   ),
   inter : WSDL!Interface (
     name <- thisModule.setElemName(i.ruleSetID, 'Interface'),
     fault <- i.rules,
     operation <- let setOfGroupIDs : Set (String) = i.rules->iterate(p; s :
Set(String) = Set{} | s->including(p.groupID) ) in
     setOfGroupIDs->collect(e| thisModule.Operation(i.rules->asSequence()->
                    select(c| c.groupID = e)->first()) )
    ),
   en : WSDL!Endpoint (
     name <- thisModule.setElemName(i.ruleSetID, 'Endpoint'),
     address <- i.rules->select(c| c.oclIsTypeOf(R2ML!ReactionRule) and not

      c.producedAction.type.oclIsTypeOf(R2ML!FaultMessageType))-> first().pro-
                                ducedAction.sender
   )
}
```

about elements from the (XML and WSDL) metamodel level (M2 level).

The next table (Table 2) shows fraction of mappings between WSDL XML schema and WSDL metamodel.

Figure 13 shows a matched rule from XML2WSDL.atl transformation for the "description" element of the XML metamodel. ATL rule Description transforms Element of the XML model (EchoService_XML) to Description (i.e. WSDL!Description) of the WSDL metamodel.

Figure 12. Transformation scenario: WSDL XML format into WSDL metamodel

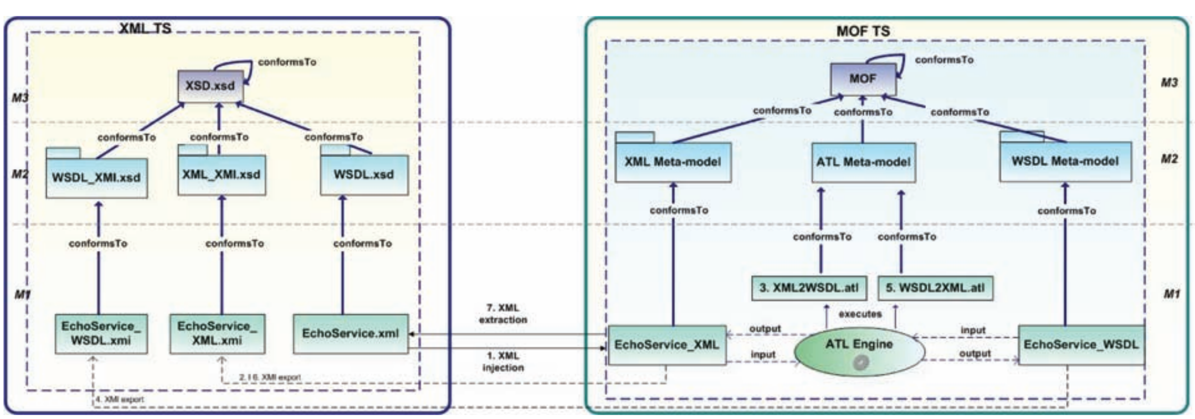

Table 2. Fraction of transformation between WSDL XML schema and WSDL metamodel

WSDL XML schema	XML metamodel	WSDL metamodel	Description
description	Root name='description'	Description	The Root element that contains types, binding, service and interface elements
interface	Element name='interface'	Interface	This element presents WSDL interface, it contains operation and fault elements
operation	Element name='operation'	Operation	This element presents WSDL operation, it contains in/outfault and in/output elements

This rule initializes "types", "interface", "binding" and "service" attributes of Description target model element by calling an ATL helper shown on the Figure 14.

The XML2WSDL transformation has 18 matched rules, one lazy rule, and 17 helpers (we have this number of helpers because we use helpers for mapping enumeration elements to their string representation – e.g. in-out MEP into the 'http://www.w3.org/2006/01/wsdl/in-out' string). The biggest problem in the XML2WSDL transformation was mapping of XML schema complex types. For solving this problem we found the (EclipseDoc, 2002) document very helpful.

Transformation of the WSDL Metamodel into the WSDL XML Schema

Transformation process from WSDL abstract syntax (i.e. WSDL metamodel) into the WSDL XML concrete syntax also contains two primary steps.

- **Step 1:** Transformation of WSDL model into XML model. Here a WSDL model (EchoService_WSDL on Figure 12) is transformed into XML model (EchoService_XML) by using the ATL transformation WSDL2XML.atl (step 5 on the Figure 12). After this transformation is executed on the input WSDL models, XML

Figure 13. Description matched rule

```
rule Description {
from
  i : XML!Element (
    i.name = 'description'
  )
to
  o : WSDL!Description (
    types <- i.getElementsByName('types'),
    interface <- i.getElementsByName('interface'),
    binding <- i.getElementsByName('binding'),
    service <- i.getElementsByName('service')
  )
}
```

Figure 14. Helpers we use in the rule in Figure 13

```
helper context XML!Element def: getAttr(n : String) : Sequence(XML!Attribute) =
  self.getChildren(n)->select(e | e.oclIsKindOf(XML!Attribute))->first();

helper context XML!Element def: getAttrVal(n : String) : String =
  let d : XML!Attribute = self.getAttr(n) in
  if d.oclIsUndefined() then
     OclUndefined
  else
     d.value
  endif;
```

models (EchoService_XML) are placed in the model repository (EchoService_XML.xmi on the Figure 12).

- **Step 2:** Transformation from MOF TS into the XML TS, where an XML model (EchoService_XML on the Figure 12) that conforms to the MOF based XML metamodel (and that is created in the step 1), is transformed into the EchoService.xml document (step 7 on the Figure 12).

In the WSDL2XML transformation, we have 17 matched rules, 3 lazy rules, as well as 5 helpers. The WSDL2XML transformation (i.e. transformation from WSDL metamodel into the WSDL XML schema) is simpler then XML2WSDL transformation (WSDL elements are directly mapped to their corresponding representation from the WSDL XML schema, and the other way around is also true).

Deploying URML Models on a Rule-Based Engine

Here, we describe the transformation process from a URML model to the Drools rule engine. For this purpose we are using an example of the in-out MEP, presented with the following business rule:

When a user sends a request for Social Insurance Number (SIN), if the authentication is successful send the SIN to the user.

This business rule is presented with one reaction rule that has a triggering event SINrequest, condition Person.Address=SINrequest.Address AND Person.Name=SINrequest.Name, and action SINresponse:

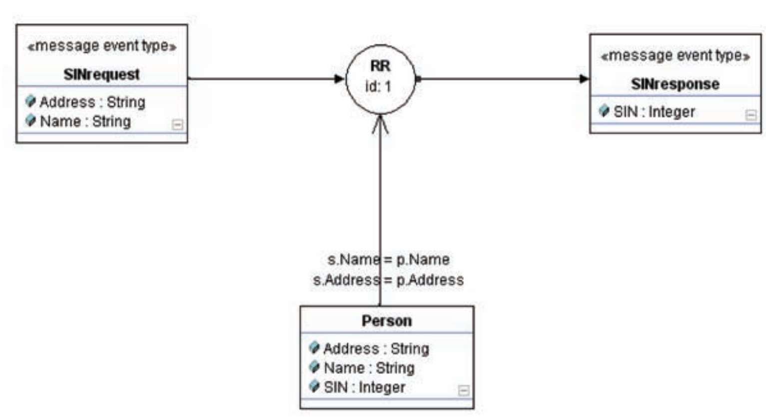
```
ON SINrequest (Address, Name)
IF Person.Address=SINrequest.
Address AND Person.
Name=SINrequest.Name
DO SINresponse(SIN)
```

An URML diagram that models the corresponding Web service operation is presented in Figure 15, and Figure 16 illustrates the R2ML presentation of it that Strelka generated for us.

The first step in getting Drools rules, from the generated R2ML file is transformation of R2ML reaction rules to R2ML production rules. The second step is transformation of R2ML production rules to Drools rules, where we are using the translation provided by (Giurca & Werner, 2006).

In order to successfully realize the first step one must address the major difference between reaction rules and production rules: reaction rules

Figure 15. URML model of the in-out MEP



have triggeringEvent element, while production rules do not have this element. So there is a need for representing triggeringEvent in production rules. If only atomic events are considered, it is legible to map the triggeringEvent element to the condition element in production rule. Figure 17 shows the corresponding R2ML production rule document that we get as the result of our transformation.

As Figure 17 shows, the producedAction part

Figure 16. R2ML serialization of URML model from Figure 15

```
    <r2ml:ReactionRuleSet r2ml:ruleSetID="ClassDiagram1">
        <r2ml:ReactionRule r2ml:ruleID="id469" r2ml:groupID="operation">
            <r2ml:triggeringEvent>
                <r2ml:MessageEventExpression r2ml:sender="not_defined" r2ml:eventType="SINrequest">
                    <r2ml:ObjectVariable r2ml:name="s" r2ml:classID="SINrequest"/>
                </r2ml:MessageEventExpression>
            </r2ml:triggeringEvent>
            <r2ml:conditions>
                <r2ml:ObjectClassificationAtom r2ml:classID="Person" r2ml:isNegated="false">
                    <r2ml:ObjectVariable r2ml:name="p"/>
                </r2ml:ObjectClassificationAtom>
                <r2ml:DatatypePredicateAtom r2ml:datatypePredicateID="swrlb:equal" r2ml:isNegated="false">
                    <r2ml:dataArguments>
                        <r2ml:AttributeFunctionTerm r2ml:attributeID="Name">
                            <r2ml:contextArgument>
<r2ml:ObjectVariable r2ml:name="p" r2ml:classID="Person"/>
                            </r2ml:contextArgument>
                        </r2ml:AttributeFunctionTerm>
                        <r2ml:AttributeFunctionTerm r2ml:attributeID="Name">
                            <r2ml:contextArgument>
<r2ml:ObjectVariable r2ml:name="s" r2ml:classID="SINrequest"/>
                            </r2ml:contextArgument>
                        </r2ml:AttributeFunctionTerm>
                    </r2ml:dataArguments>
                </r2ml:DatatypePredicateAtom>
 <r2ml:DatatypePredicateAtom r2ml:datatypePredicateID="swrlb:equal" r2ml:isNegated="false">
                    <r2ml:dataArguments>
                        <r2ml:AttributeFunctionTerm r2ml:attributeID="Address">
                            <r2ml:contextArgument>
<r2ml:ObjectVariable r2ml:name="p" r2ml:classID="Person"/>
                            </r2ml:contextArgument>
                        </r2ml:AttributeFunctionTerm>
                        <r2ml:AttributeFunctionTerm r2ml:attributeID="Address">
                            <r2ml:contextArgument>
<r2ml:ObjectVariable r2ml:name="s" r2ml:classID="SINrequest"/>
                            </r2ml:contextArgument>
                        </r2ml:AttributeFunctionTerm>
                    </r2ml:dataArguments>
                </r2ml:DatatypePredicateAtom>
            </r2ml:conditions>
            <r2ml:producedAction>
                <r2ml:MessageEventExpression r2ml:eventType="SINresponse"/>
               <r2ml:ObjectVariable r2ml:name="SIN" r2ml:classID="SINresponse"/>
            </r2ml:producedAction>
        </r2ml:ReactionRule>
    </r2ml:ReactionRuleSet>
</r2ml:RuleBase>
```

Figure 17. Generated R2ML production rule document – part of rule containing conditions is shown on left – vocabulary part can be seen on the right

of the generated production rule is the same as in the reaction rule, while the conditions part is constituted from conditions of a reaction rule along with the triggeringEvent of reaction rule. Also, a vocabulary part of production rule is updated with the adequate class generated from triggeringEvent of reaction rule. (i.e. if no such class is already defined. This situation happens with the presentation of rules in older versions of R2ML). Table 3 provides a brief overview of the transformation from Reaction Rules to Production Rules.

Once we have generated a R2ML production rule from the R2ML reaction rule, we use the transformation provided by (Giurca & Werner, 2006) to transform R2ML production rule to a Drools rule. Figure 18 shows the generated Drools rule from the production rule presented in Figure 17. The left part of this figure shows the classes generated for Drools engine, and the right part of the figure shows the rule itself. Each rule fires an action when conditions are met - in the case below, SINrequest trigger this rule, while SINresponse is fired as the response to the information requested.

Table 4 presents the concept of transformation between R2ML production rule elements and the Drools generated code. The table is not presenting all steps of transformation as some of them are not a simple mapping between elements but gives a general idea of what is done.

6. RELATED WORK

In this section, we compare the proposed approach with some relevant solutions to the modeling of Web services that are based on the MDE principles.

(Bezivin et al., 2004) demonstrate how one can take advantage of MDE to develop e-business applications. In their approach, they start from UML and the UML profile for Enterprise Distributed Object Computing (EDOC) to define platform-independent models of e-business applications.

Table 3. Presenting the basic of transformation from reastion rule to production rule

Reaction Rule	Production Rule
ReactionRuleSet	ProductionRuleSet
ReactionRule	ProductionRule
TrigerringEvent & Conditions	Conditions (There will be only one Conditions element generated although both TrigerringEvent and Conditions could be present in the Reaction Rule)
MessageEventExpression	ObjectClassificationAtom

In the next step, they translate such models into models that are based on metamodels of Java, WSDL, and JWSDP. Although this approach uses ATL, similar to what we do, it does not provide two way transformations between models and service implementation. This is unlike our solution, because we support two-way transformations, and thus we enable reverse engineering of the existing Web services. Next, the translation of regular UML models, i.e., UML class related elements into WSDL is limited, as one does not have enough expressivity in UML diagrams to define all details of WSDL (i.e., one can not distinguish between input and output messages). This issue is addressed by using the UML profile for EDOC, but this approach is more focused on modeling distributed components rather on modeling business logics. In our approach, the use of reaction rules in URML models enables us to be closer to business processes, while OCL filter expressions can even further specify conditions under which a message can happen. This is very useful for potential integration of business process based on the use of Web services (Milanovic et al., 2006). Of course, such filter expressions overcome the potentials of the Web service technology, as they presume that there should also be a rule-based engine, which is able to interpret such conditions. However, the research on semantic Web services (Sheth et al., 2006) and Web rules (Nagl et al., 2006) demonstrates that this issue attracts more attention in the Web service research community.

(Vara et al., 2005) define a metamodel for WSDL and its corresponding UML profile that is used for modeling of Web services in the MIDAS-CASE MDA-based tool for Web information system development. They also support automatic generation of the respective WSDL description for

Figure 18. Generated Drools rule (right) and generated class of it (left)

```
public class Person {
    public string Address;
    public string Name;
    public integer SIN;

    #conditions
        p : Person()
        s : SINrequest()

        p : Person ( namePerson : Name )
        p : Person ( addressPerson : Address )
        s : SINrequest ( nameSINrequest : Name )
        s : SINrequest ( addressSINrequest : Address )

        eval (nameSINrequest.compareTo( namePerson ) == 0 )
        eval (addressSINrequest.compareTo( addressPerson ) == 0 )

  then
    #actions
        SIN : SINresponse()

end
```

Table 4. Presenting transformation concept of R2ML production rule to Drools

R2ML	Drools
Class	Class
Attribute	Integer, String etc (Based on the value of r2mlv:ID)
Conditions	Conditions (and based on the object within this element the condition element will be generated)
producedAction	Actions (based on the elements residing within this element proper code with regards to the previously generated classes will be generated)

the Web services that is being modeled. Although the MIDAS framework supports platform-independent models of services and service compositions, their definitions are very incomplete and one can hardly generate complete service models automatically. In our approach, we do not strictly base models of services on workflows in which services will be used, as we wanted to focus on how services are used (i.e., MEPs).

(Gronmo et al., 2005) and (Timm & Gannod, 2005) propose an approach to modeling semantic Web services by using UML profiles. Gronmo et al. have the goal to define platform-independent models of services, which can be translated to semantic Web services (OWL-S and WSMO). In their work, they abstract concepts from OWL-S and WSMO, and extend UML activity diagrams (i.e., they define a UML profile) accordingly, while for defining vocabularies they use the Ontology Definition Metamodel, and its corresponding UML profile defined in (Gasevic et al., 2005). Since both these approaches use XSLT, they can hardly translate service pre- and post-conditions from their UML definitions (i.e., OCL) to the languages of the potential target platforms (e.g. Jess). This approach does not consider modeling usage patterns or MEPs or error handling (i.e., business logic) like we do, but instead it focuses on the details specific for service platforms.

(Manolescu, et al., 2005) propose a model-driven approach to designing and deploying service-enabled web applications. This work is different from the ones above in the following aspects: i) it extends WebML, a well-known modeling language for developing Web applications; ii) it uses E-R models for defining data types; and iii) it focuses on the usage patters (MEPs) of Web services in order to define WebML extensions. Their modeling approach is based on the use of MEPs, but they are considering MEPs used in WSDL 1.1, and for each MEP they define corresponding WebML primitive. These new WebML primitives can be used in hypertext models of Web applications. This approach is the most similar to ours; both approaches fully focus on modeling business processes and potential usage patterns. However, the WebML approach does not explicitly define a Web service

Table 5. Summary of solutions for modeling of Web services based on the MDE principles

Approach	Used metamodel	Model description	transformation	output
(Timm & Gannod, 2005)	UML profile	UML XMI	XSLT	OWL-S
(Bezivin et al., 2004)	MOF	MOF XMI	ATL	WSDL, Java, JWSDP
(Manolescu, et al., 2005)	Extended WebML	WebML model	XSLT (through visual editor)	WebRatio output
(Vara et al., 2005)	UML profile	UML XMI	MIDAS-CASE transformation unit	MIDAS output
Our approach	MOF	MOF XMI	ATL	R2ML, WSDL

description, but it infers it from the definitions of hypertext models in which the service is used, which makes this process context dependent. That is, services are defined inside specific WebML workflows unlike our approach where we define workflow-independent services. In addition, they do not consider the use of preconditions of Web services, which is important for the reusability of services in different contexts. Although WebML has support for exception handling (Brambilla et al., 2005), this is also focused on the workflow level rather than on a service level. Finally, the WebML approach does not support reverse engineering of Web services.

The following table (Table 5) summarizes these approaches of modeling of Web services, and shows their relation to our approach we describe in this paper.

7. CONCLUSION

In this paper, we have demonstrated how the use of MDE principles can enable for rule-based modeling of Web services. By using the MDE principles, we have been able to develop a framework for modeling Web services from the perspective of how services are used in terms of message-exchange patterns (MEPs). Our approach enables developers to focus on the definition of business rules, which regulate MEPs, instead of focusing on low level Web service details or on contexts where services are used (i.e., workflows). Business rules are important assets of a business organization that embody valuable domain knowledge. They are stated in a way, which is very close to how users think and talk. Due to the declarative nature of rules, the business logic can easier be updated without the need to change to whole system. Furthermore, integrating business rules in process-oriented Web service composition can improve the quality and ease development. Once business rules are expressed explicitly as first-class entities, they can be reused across several compositions i.e., the same rule can be applied to many web service compositions.

By leveraging MDE, we have defined a rule-based modeling language that can be managed by universal MDE tools. The use of model transformations allows for transforming platform independent models of business logic to specific platforms such as Web services. Moreover, for each Web service, we can also generate a rule that will fully regulate the behavior of the service (i.e., how the service is used), and thus make sure that the business logic is fully followed. In this paper, we have not explained that part of the solution, but we are going to report on that in our future papers.

Our solution has much broader potentials that overcome the pure translation between rule-based business models and Web services. Unlike the WSDL definition of Web services, our models also have an option for defining pre- and post-conditions of services. However, WSDL can not express pre- and post-conditions in the descriptions of Web services. That is, Web service tools can not automatically support conditions under which some services can be used (as defined by OCL filters in Section 4). To address this problem, we expand our approach on W3C's Semantic Annotations for WSDL (SAWSDL) recommendation. In our current activities, we have developed transformations from our R2ML reaction rule-based models to several production rule languages (e.g., Drools, Jena2, and Jess). Our particular focus is on Drools, as the use of Drools allows us to directly enforce business rules to regulate the use of Web services deployed on JBoss' application server.

KEY TERMS AND DEFINITIONS

Business Rules: Business rules or business rule sets describe the operations, definitions and constraints that apply to an organization in achieving its goals.

Drools: A business rule management system (BRMS) with a forward chaining inference based rules engine, more correctly known as a production rule system, using an enhanced implementation of the Rete algorithm.

Reaction Rules: Also known as Event-Condition-Action Rules, are three components rules i.e. the *event* part specifies the signal that triggers the invocation of the rule, the *condition* part is a logical test that, if satisfied or evaluates to true, causes the action to be carried out and the *action* part consists of updates or invocations on the local data.

R2ML: REWERSE I1 Rule Markup Language, a rule markup language allowing rules interoperability.

URML: UML-based Modeling Language, a visual language for rules modeling.

Web Service: A software system designed to support interoperable machine-to-machine interaction over a network.

WSDL: Web Service Description Language is a language for describing both the abstract functionality of a service and the concrete details of a Web Service.

Chapter 2.14

A Semantic Web-Based Approach for Building Personalized News Services

ABSTRACT

This article proposes Hermes, a Semantic Web-based framework for building personalized news services. It makes use of ontologies for knowledge representation, natural language processing techniques for semantic text analysis, and semantic query languages for specifying wanted information. Hermes is supported by an implementation of the framework, the Hermes News Portal, a tool which allows users to have a personalized online access to news items. The Hermes framework and its associated implementation aim at advancing the state-of-the-art of semantic approaches for personalized news services by employing Semantic Web standards, exploiting domain information, using a word sense disambiguation procedure, and being able to express temporal constraints for the desired news items.

INTRODUCTION

The simplicity, availability, reachability, and reduced exploitation costs have made the Web one of the most common platforms for information publishing and dissemination. This is particularly true for news agencies that use Web technologies to present emerging news regarding different types of events as for example business, cultural, sport, and weather events. Most of this information is published as unstructured text that is made available to a general audience by means of Web pages.

The heterogeneity of the Web audience and the diversity of the published information asks for more refined ways of delivering information that would enable users to access news items that interest them. For this purpose the Really Simple Syndication (RSS) (Winer, 2003) standard was developed that publishes information in a semi-structured format that supports machine processing. This format is based on metadata that (1) associates news items with channels (feeds) that have properties like categories (e.g., business, sport, politics, etc.), title, publication date, etc., and (2) describes news items by means of their properties as categories (e.g., online business, business system, Internet marketing, etc.), release time, title, abstract, link to the original published information, etc.

Most of the annotations supported by the RSS feeds are coarse-grained in the sense that they fail to identify the different topics addressed in a certain news item. Also, the current annotations are only partially processable by machines as the tags do not have unique semantic meaning associated to them and thus have different interpretations. Being able to understand the semantic content of a news item would enable a fine-grained categorization of this information, thus better supporting the users (casual users, media analysts, stock brokers, etc.) information needs.

In order to make the Web data not only machine readable but also machine understandable the World Wide Web Consortium proposes the Semantic Web (Berners-Lee, Hendler, & Lassila, 2001), a sequence of technologies that allow for self-describing content. On the Semantic Web metadata is defined using semantic information usually captured in ontologies. Some of the most popular formats to describe ontologies on the Semantic Web are RDF(S) (Klyne & Carroll, 2004) (Brickley & Guha, 2004) and OWL (Bechhofer et al., 2004).

A special class of users who make daily use of (emerging) news is that of stock brokers. Because news messages may have a strong impact on stock prices, stock brokers need to monitor these messages carefully. Due to the large amounts of news information published on a daily basis, the manual task of retrieving the most interesting news items with respect to a given portfolio is a challenging one. Existing approaches such as Google Finance or Yahoo! Finance are developed to meet these personalization needs by supporting automatic news filtering on the Web.

Current approaches to news filtering are able to retrieve only the news that explicitly mention the companies involved, failing to deliver indirect information which is also deemed relevant for the considered portfolio. For example, for a portfolio based on Google shares, such systems fail to deliver news items related to competitors of Google, such as Yahoo! or Microsoft, which might have an indirect influence on the share price of Google. Exploiting the semantic contextual information related to companies such as its competitors, CEO's, alliances, products, etc., enables a more comprehensive overview of relevant news with respect to a certain portfolio.

Another limitation of existing news filtering systems is their inability to cope with delivering news items satisfying temporal constraints. The time aspect is of utmost importance when, for example, one considers the fact that news items usually have an immediate impact on stock prices, or when one desires to do a historical analysis of past news and stock price evolutions. Being able to exploit the timestamps associated to news items enables retrieving only news that obey user-determined time-related constraints.

In this article we propose the Hermes framework, a semantic-based approach for retrieving news items related, directly or indirectly, to the concepts of interests from a domain ontology. In addition these news items might need to satisfy temporal constraints. For illustration purposes we focus here on the NASDAQ stock market domain (Kandel & Marx, 1997), but the genericity of our approach makes it applicable also to other domains, as, e.g., tourism or scientific domains. The Hermes News Portal (HNP) is an implementation of the Hermes framework, which allows the user to specify queries for the concepts of interest and temporal constraints, and retrieve the corresponding news items.

For HNP we make use of Semantic Web technologies like OWL (Bechhofer et al., 2004) for formally defining the semantics of the concepts of interest in the ontology. We employ natural language processing (NLP) technologies as, e.g., lexical analysis, gazetteering, word sense disambiguation, etc., for indexing news items based on ontology terms. The most popular Semantic Web query language SPARQL (Prud'hommeaux & Seaborne, 2008) is used for expressing queries using the previously identified concepts. In order to simplify the representation of temporal constraints we propose time-related extensions to SPARQL. HNP is a generic platform that could easily be applied to other domains than the financial one.

The structure of the article is defined as follows. The first section discusses related approaches for personalized news services. The second section presents the Hermes framework identifying the proposed methodological steps. The third section describes HNP, an implementation of the proposed framework. The last section concludes the article and discusses future work.

RELATED WORK

Among the methods that aim at personalizing news information we distinguish two types: non-semantic approaches and semantic approaches. In the followings we will present short descriptions of two non-semantic methods: Server for Adaptive News and YourNews, and two semantic methods: MyPlanet and SemNews. For each presented method we give the differences compared to our approach and at the end of this section we highlight the main contributions of the Hermes framework.

Server for Adaptive News (SeAN) (Ardissono, Console, & Torre, 2001) enables a personalized access to news servers on the Web. The generated views are composed of sections, as in newspapers, on which customized news items are embedded. The news items are viewed as complex entities in which attributes define different components, e.g., title, abstract, text, photos, videos, commentaries, etc. The system employs a user model initialized using orthogonal stereotypes (interests, domain expertise, cognitive characteristics, and life styles) for which the user is asked to provide input and is further updated using rules that exploit the user behavior with the application. Taking into account the user model, the system builds a presentation based on relevant news items, each news item being shown at an appropriate level-of-detail (based on the user model). Differently than SeAN, our framework uses standard Semantic Web technologies for representing knowledge and employs NLP techniques for automatic annotation of news items, instead of using a manual approach.

YourNews (Ahn, Brusilovsky, Grady, He, & Syn, 2007) proposes an open and editable user model for personalizing news items. The user model is open in the sense that users can view the list of keywords stored in the individual profiles. The user model is also editable as it allows users to add/delete keywords from their associated profiles. As an additional feature which also contributes to the transparency and control over adaptation, YourNews shows the key terms present in news items. The representation of news items is given by weighted vectors of terms (Salton, 1971), where the weights are computed using TF-IDF (Salton & McGill, 1983). The visited news items are used for building a weighted term vector which is the user model. The similarity between a news item and the user model is defined by the cosine metric between their associated vectors. This measure allows the system to recommend news items that are considered relevant for the user. Despite the users' interest to view and edit their profiles, there is a decrease in performance (e.g., precision, recall, etc.) for recommended items compared to the same system using a closed user model (where the user is not able to view/edit the user model). While YourNews uses a keyword-based approach for modeling news items and user interests, Hermes employs a semantic approach based on ontology concepts for modeling similar aspects.

MyPlanet (Kalfoglou, Domingue, Motta, Vargas-Vera, & Shum, 2001) aims at providing users with news items relevant for their topics of interest. MyPanet is an extension of PlanetOnto, an integrated suite of tools used to create, deliver, and query internal newsletters of the Knowledge Media Institute (KMi). Similar to our approach an ontology is used for classifying news items and allowing the user select his topics of interest. Nevertheless, the classification process is based on the heuristics of cue phrases attached to ontology concepts, while we have a more systematic approach to classification by employing NLP techniques (e.g., exploiting the WordNet term synonyms, performing word sense disambiguation, etc.) that improve classification results. In addition, our implementation is based on the standard ontology language OWL instead of the specific ontology language, OCML (Motta, 1999), used in myPlanet. We also did choose to present the ontology as a graph instead of a tree as it allows the user to have a more comprehensive overview of the ontology structure.

SemNews (Java, Finin, & Nirenburg, 2006) proposes a framework for understanding and querying news items. As in Hermes, the monitored news are made available by RSS feeds. The news items are analyzed by OntoSem (Nirenburg & Raskin, 2001), SemNews' natural language processing engine. OntoSem converts the textual representation of news into Text Meaning Representation (TMR), a specific format for knowledge representation. The TMR descriptions are subsequently converted to OWL and published on the Web. The OWL news representation can be used for querying using RDQL (Seaborne, 2004), one of the precursors of the SPARQL query language. Differently than SemNews, Hermes uses a semantic lexicon (e.g., WordNet) for performing word sense disambiguation, and allows for a more intuitive way of building queries by letting the user make his selections in a graphical way.

The contributions that Hermes brings to building personalized news services compared to existing approaches are fivefold. First, Hermes makes a strict distinction between the framework (Hermes framework) and its implementation (HNP), allowing for possible different technologies (as these evolve) to be used with the same framework. Second, Hermes uses an advanced NLP methodology (e.g., tokenization, part-of-speech tagging, word sense disambiguation, etc.) for news understanding employing a semantic lexicon (e.g., WordNet). Third, the implementation is based on the most up-to-date Semantic Web standards (OWL and SPARQL). Fourth, we allow news querying using temporal constraints by providing temporal extensions to SPARQL. Fifth, and the last contribution, the user is provided with a graphical query interface to specify the concepts of interest in a direct (using concept selections) or indirect manner (using relationship selections).

HERMES FRAMEWORK

The Hermes framework proposes a sequence of steps to be followed in order to build a personalized news service. The input for the constructed system comprises RSS news feeds and the output consists of news items fulfilling user needs. The Hermes framework is centered around a domain ontology which is used for indexing news items and helping the user formulate queries based on his concepts of interest. In addition, the user can specify temporal constraints that news items need to satisfy. The resulting news items are sorted based on their relevance for the user queries.

For illustrative purposes we chose a financial domain example, i.e., a personalized news service which can help the stock brokers in their daily decisions. More precisely we opted for portfolios based on stocks of NASDAQ companies. For this purpose we developed a domain ontology, which captures companies, products, competitors, CEO's, etc. In addition we have developed a news ontology able to store news items and their metadata such as title, abstract, time stamp, etc.

The domain ontologies are developed by domain experts. The process of developing the ontology is an incremental middle-out approach. First the most salient concepts are defined and then these are refined using generalization/specialization towards the top/bottom of the ontology. As the news information can contain additional concepts not a priori known, the ontology needs to be regularly maintained by the domain experts. We validated our domain ontology using the OntoClean methodology (Guarino & Welty, 2002).

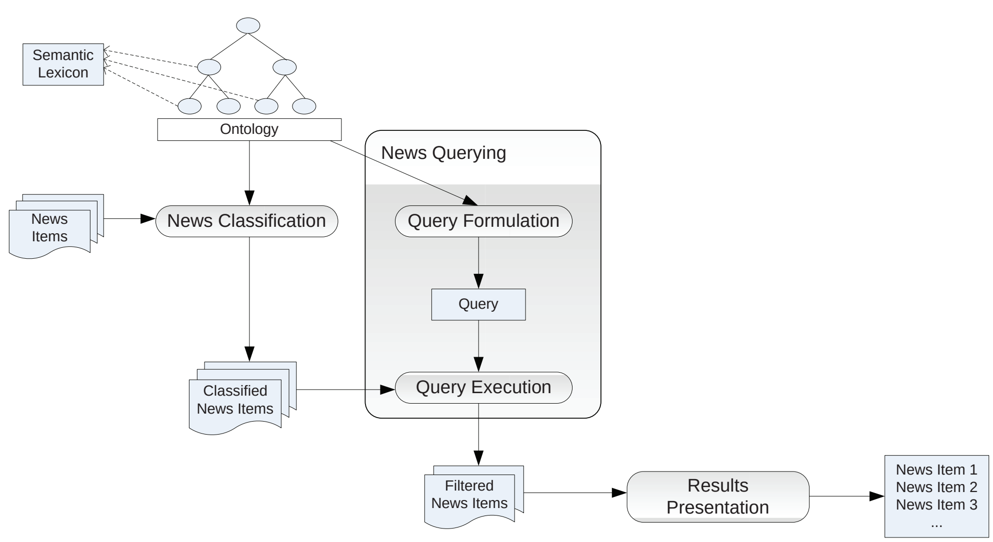
As news items might come from different RSS feeds, it is possible that the same news item has been published through different channels. After aggregating the news items one needs to remove the duplicate ones. In order to speed-up this process we employed the heuristics to use only the title for identifying news items, even so we acknowledge that in few cases news items might have the same title and still have different content, i.e., they represent different news items.

The architecture of the Hermes framework is described in Figure 1 and is composed of three main steps: *news classification*, *news querying*, and *results presentation*. *News classification* is responsible for indexing the news items based on ontology concepts. *News querying* consists of two substeps: *query formulation*, i.e., helping the user build the query that expresses the items of interest, and *query execution*, i.e., computing the results of query evaluation. In the last step, *results presentation* the computed news items are presented based on their relevance to the user interests.

NEWS CLASSIFICATION

The ontology concepts used for news items classification are classes and individuals from the domain ontology. Concepts are linked to synsets, i.e., sets of synonyms, from a semantic lexicon, which identify their unique meaning. The synonyms stored in a synset in the semantic lexicon are used as lexical representations of the associated

Figure 1. Hermes architecture



concept. In this case a lexical representation has a sense associated with it, i.e., the one given by the corresponding synset. As the ontology is specific to a domain, while the semantic lexicon is domain independent, we associate additional domain specific lexical representations to the concepts in our ontology. The lexical representations are composed only of word lemmas (the canonical word form appearing in dictionaries).

In addition, for classes without subclasses and individuals we decided to consider the hyponyms associated to their corresponding semantic lexicon synset. For these classes and individuals, the domain expert, who devised the ontology, is probably not interested in more refined definitions of these. However, the lexical representations of these concepts can be enlarged by considering also the corresponding hyponyms synsets from the semantic lexicon.

The classification approach is *ontology-centric*, in the sense that the ontology concepts are loaded one at-a-time and their lexical representations are matched against the news items. This approach is opposed to a *news items-centric* one where the words in the news items are matched against the lexical representations of the concepts from the ontology. We opted for an ontology-centric approach in order to speed-up the classification process as in this case we need to traverse the ontology only once. The number of concepts in the ontology is considerably larger than the number of words in the news items.

First the tokenization, sentence splitting, part-of-speech tagging, and morphological analysis are performed. The tokenization precedes sentence splitting as sentence splitting needs the identification of the punctuation signs from tokenization (as ".", ",", etc.). Morphological analysis follows part-of-speech tagging because the lemma of a word depends on its part-of-speech tag. For example "reading" as a verb has lemma "read" but as noun it has the lemma "reading". In this way, all words in a news item are reduced to their canonical form, a form shared also by the lexical representations of concepts stored in the domain ontology. For lexical representation identification we use the maximal group of words (compound words) found in sequence in a news item that stand for a concept's lexical representation. For example "European Central Bank" would be identified as a compound word representing the ECB concept, e.g., a longer match supersedes a shorter match.

Each time a lexical representation of a concept is matched a *word sense disambiguation* procedure takes place. As the same lexical representation can belong to different concepts (present or not in the ontology) this procedure checks if the match indeed corresponds to the meaning of the found ontology concept. If the check is positive a *hit* is stored in the ontology, i.e., a link between the news item and the corresponding concept is defined. The hit also stores the found lexical representation, as classification evidence.

For word sense disambiguation we use a variant of the SSI algorithm (Navigli & Velardi, 2005). In this process we also consider lexical representations for concepts that are not stored in the ontology but are present in the semantic lexicon as these are relevant when computing the sense of a found lexical representation from the ontology. These lexical representations help in better determining the context of a sentence and thus computing the sense of an ontology-based lexical representation.

The algorithm determines, per news sentence, the sense of a lexical representation (*lex*) by computing the sum of the distances between one of the senses of the considered lexical representation (s_j) and the senses of the previously disambiguated lexical representations from the context sentence (sc_i). The sense corresponding to the smallest sum is the chosen one (*selectedSense*). The algorithm starts with monosemous lexical representations (i.e., lexical representations which correspond to only one concept) and in case that such representations do not exist a guess is made by picking the most common sense for one of the found lexical

Box 1.

$$selectedSense(lex) = \arg \min_{s_j \in senses(lex)} \sum_{sc_i \in I} d(s_j, sc_i) \qquad (1)$$

representations. These senses are added to the context (I) of the sentence. For each remaining polysemous lexical representations two steps take place: a disambiguation step to find the correct sense and an insertion step which adds the newly computed sense to the context. In this way the context gets enlarged with new senses that model the meaning of the sentence. Formula (1) specifies what sense is selected for each lexical representation (See Box 1).

The distance between senses is defined as being inverse proportional with the length of the shortest path between the corresponding synsets ($sense_i$ and $sense_j$) in the semantic lexicon graph. The graph is based on the hypo/hypernyms relationships stored in the semantic lexicon. Path lengths larger than a predefined constant (e.g., 4 or 5) are not used (for these cases the distance is considered infinite). In this way we employ only semantically close concepts that truly help in the disambiguation procedure and also improve the speed of the process by not using arbitrarily large paths. Formula (2) shows how to compute the distance between two senses (See Box 2).

As the distances between synsets are not changing, one can pre-compute these, thus further reducing the time needed for the disambiguation step. The Hermes framework can be used with other methods for computing the similarity between concepts as for example string metrics (e.g., Levenshtein, Editex, etc.) or lexical co-occurrences in a corpus (e.g., pairwise mutual information, Google distance, etc.). Nevertheless, many of these methods are less precise than the graph-based method used here, as they do not take in account senses, comparing only the lexical representations of concepts.

NEWS QUERYING

The user expresses the topics of interests by posing queries using concepts from the domain ontology. In addition the user can express constraints that the timestamps associated to news items need to satisfy. The news querying step consists of two substeps: query formulation, i.e., supporting the user to build queries, and query execution, i.e., computing the results of query evaluation. Below we present in detail each of these substeps.

Query Formulation

In order to assist the query construction process we present to the user the ontology graph. We decided to show a graph-based representation of the ontology instead of a tree-based representation, as it gives more insight in the overall structure of our domain. For example a graph representation captures more relationship types instead of a singular relationship type, often the subsumption relationship, from a tree-based representation. The

Box 2.

$$d(sense_i, sense_j) = \frac{1}{length(shortestPath(synset(sense_i), synset(sense_j)))} \qquad (2)$$

user needs to understand the different relationship types in order to be able to build his query.

By using the ontology graph the user can select the *direct concepts of interest*. In addition he is able to specify concepts of interest using a keyword search facility through the graph. For this purpose the input keyword is checked for possible inclusion in the lexical representations of concepts. If such inclusions are found the corresponding concepts are being returned as possible direct concepts of interest. It is the task of the user to accept these as direct concepts of interest or to reject them.

One of the important functionalities of the Hermes approach is that it allows for the selection of concepts indirectly linked to the selected ones, concepts which are not a priori known to the user. We call these concepts *indirect concepts of interest*. For the selection of the indirect concepts of interest the user can state the type of the relationships that links the direct concepts of interest to the indirect concepts of interests or leave this undefined in which case all relationship types are being considered.

Suppose that the user has selected the direct concept of interest Google from the NASDAQ domain ontology. The user also specifies that he is interested in news related to the competitors of `Google` by selecting the `hasCompetitor` relationship. That means that `Yahoo!`, `Microsoft`, and `EBay` will be selected as indirect concepts of interests, without the user having to know the exact names of Google's competitors. All this background information is being extracted from the ontology.

The direct, indirect, keyword-based search concepts of interest, and the other concepts from the ontology need to be emphasized in a graph by using for example different colors. In this way the user is able to know, by analyzing the graph, why a certain concept is being highlighted. As the size of the graphs can be very large the user is provided with zooming/panning facilities for visualizing the ontology.

The original graph of the domain ontology is also called the *conceptual graph*. Based on the user selection, a new graph is generated, the so-called *search graph* that contains only the concepts and concept relationships relevant for the query. The user can go back and forth between the two graphs performing new selections and thus updating the search graph with new concepts.

The search graph is given by the subgraph of the conceptual graph that models the user interests which is equivalent to the answer of a conjunctive query based on selected binary predicates and concepts (that form graph patterns) while keeping the selected relationships between the concepts in the result set. The search graph has disjunctive semantics with respect to the included concepts which means that the user is interested in *any* of the search graph concepts.

Another crucial functionality of the Hermes approach is that it allows the specification of temporal constraints for news items. As news items appear at a certain moment in time and have certain time validity, it is important to be able to restrict the timestamps associated with the news. For this purpose the user can employ time comparison/arithmetic operators and retrieve the current time in order to build complex time expressions. In addition the system provides predefined temporal constraints such as: last day, last week, last two weeks, last three months, last quarter, last half year, and last year. The temporal conditions that model these constraints have conjunctive semantics as they need to be fulfilled in the same time.

Query Execution

Based on the previously selected concepts and specified temporal constraints the system can support the generation of the corresponding query in a semantic query language. This translation process involves mapping concepts and temporal constraints to query restrictions. After that, the user can trigger the query evaluation and the relevant news items are retrieved. The order of the retrieved news items is not relevant, at this stage.

RESULTS PRESENTATION

The results returned from query evaluation are presented in the order of their relevance for the user query. For this purpose, for each returned news item a *relevance degree* is computed based on all the hits between the news item and the query concepts. News items with high relevance degree are placed at the top of the retrieved news items list.

Based on previous work (Micu, Mast, Milea, Frasincar, & Kaymak, 2008) the relevance degree is defined as a weighted sum of the number of hits ($n(c_i)$), where the weights (w) depend on hits location (*title* or *body* of a news item). From our experimental results we have determined as acceptable values for w_{title} to be *2* and for w_{body} to be *1.* Formula (3) presents how to compute the relevance degree (See Box 3).

News items that have the same relevance degree are sorted in descending order based on the associated timestamps (the most recent news items are presented first).

In addition to presenting the relevant news items, the system shows the query concepts in order to provide cues of the current query for which the results are computed. Also, for each returned news item, the found lexical representations stored in the hits are emphasized in the news item text, thereby offering to the user an explanation of why a certain news item is considered to be relevant.

HERMES NEWS PORTAL

The Hermes News Portal (HNP) is an implementation of the Hermes framework, which allows the user to specify queries on the considered domain using temporal constraints and subsequently retrieve the relevant news items. The presentation of HNP follows closely the steps proposed by the Hermes framework. Note that HNP is one of the possible implementations of the Hermes framework, with specific design choices, query/programming languages, and libraries used.

Operating on the Semantic Web we chose as ontology language OWL due to its expressivity and standard status. We did not opt for RDFS because OWL specific features, as for example relationships inverses (`hasCompetitor` has as inverse `isCompetitorOf`), are exploited in the conceptual graph. Lacking a true OWL query language we used SPARQL as the query language, an RDF query language that we extended with time-related functionality. This functionality is provided by implementing comparison/arithmetic time operators and functions for retrieving current time information.

The chosen implementation language is Java due to the availability of powerful libraries for manipulating, reasoning with, querying, and visualizing OWL ontologies. For manipulating

Box 3.

$$relevanceDegree(news\ item) = \sum_{\substack{c_i\ found\ in\ title \\ c_i \in O \cap news\ item}} w_{title}\, n(c_i) + \sum_{\substack{c_i\ found\ in\ body \\ c_i \in O \cap news\ item}} w_{body}\, n(c_i) \qquad (3)$$

Figure 2. News item example

Google to broker print ads in newspapers
6 November 2006 17:41 CET

SAN FRANCISCO (Reuters) - Google Inc. is set to begin helping customers buy advertisements in 50 U.S. newspapers in a test of how the Web search leader can extend its business into offline media, the company said on Sunday.

and reasoning with OWL ontologies we used Jena (Jena Development Team, 2008a). For querying we employed ARQ (Jena Development Team, 2008b), the SPARQL implementation available in Jena. For visualizing ontologies we adapted the generic graph visualization library Prefuse (The Berkeley Institute of Design, 2008) for visualizing OWL graphs (Borsje & Giles, 2008). For part-of-speech tagging we used the Stanford parser (The Stanford Natural Language Processing Group, 2008). As a semantic lexicon we employed WordNet (Princeton Cognitive Science Laboratory, 2008), the largest database available online for the English language. JWI (Finlayson, 2008) was used for the morphological analysis (finding lemmas of words) and the communication with WordNet.

We illustrate the HNP by means of the following user query: *retrieve all news items related to Google or one of its competitors that appeared in the last three months.* For this query we will go through all the different phases of Hermes: news classification, news querying, and results presentation. In the current HNP the news items duplicates removal has not been yet implemented.

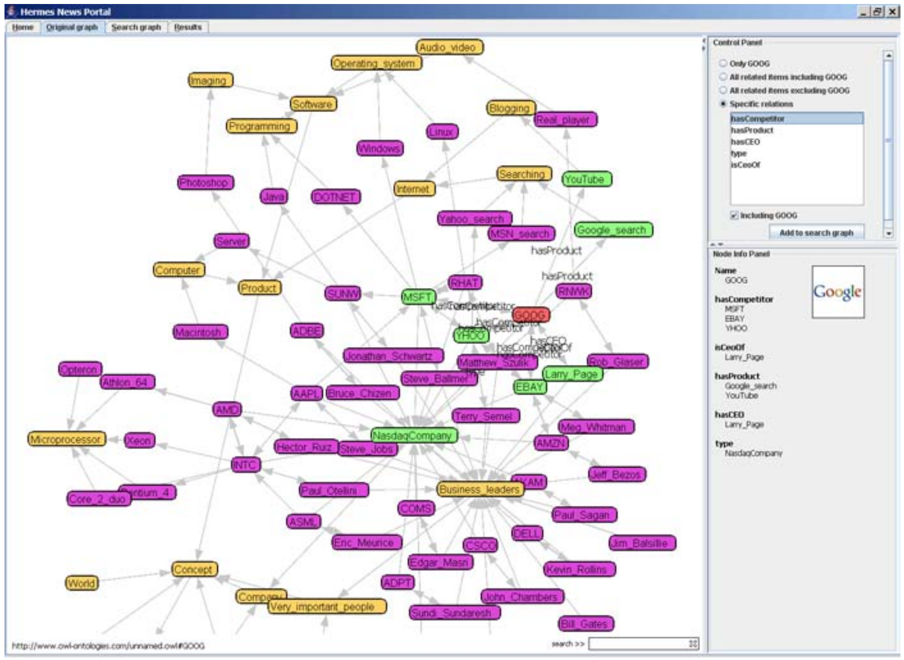
NEWS CLASSIFICATION

The news classification step is responsible for indexing news items based on the domain ontology. We present this process by means of the news item example depicted in Figure 2. The first line describes the title, the second line shows the timestamp, and the remaining text represents the content of the news item.

The news classification step starts by identifying lexical representations of the ontology concepts in the news item. First the tokenization, sentence splitting, part-of-speech tagging, and morphological analysis take place. Then, the concepts from the ontology are traversed once and their lexical representations are matched against the content of the news item. The following lexical representations "Google", "extend", and "company" are found. Next, per sentence, for each of the lexical representations with multiple senses, the word sense disambiguation procedure takes place in order to identify the used senses. The noun "Google", having only one sense, doesn't undergo the word sense disambiguation procedure and is mapped to the Google concept.

For "extend" and "company" a word sense disambiguation procedure is needed. In this process we do consider also lexical representations of concepts outside the ontology, as for example the nouns "customer" and "business", or the verb "buy" that do appear in the news item. We select the sense that yields the smallest sum of similarities to previously disambiguated lexical representations. For "extend" it is determined as representing the `extend-verb-#1` concept with lemma extend, part-of-speech tag `verb`, and the first sense from WordNet. For "company" the corresponding concept is `company-noun-#1`. "customer", a lexical representation outside the ontology, is determined as having the sense `customer-noun-#1`.

Figure 3. Conceptual graph example



After identifying an ontology concept in a news item, a hit is stored. This hit is defined as a link between the news item and the concept together with the found lexical representation. For this purpose we decided to model a hit as an instance of the `Relation` class, which uses different properties for storing the involved news item, concept, and found lexical representation. This modeling choice is based on a best practice for modeling N-ary relations on the Semantic Web (Noy & Rector, 2006).

NEWS QUERYING

Query Formulation

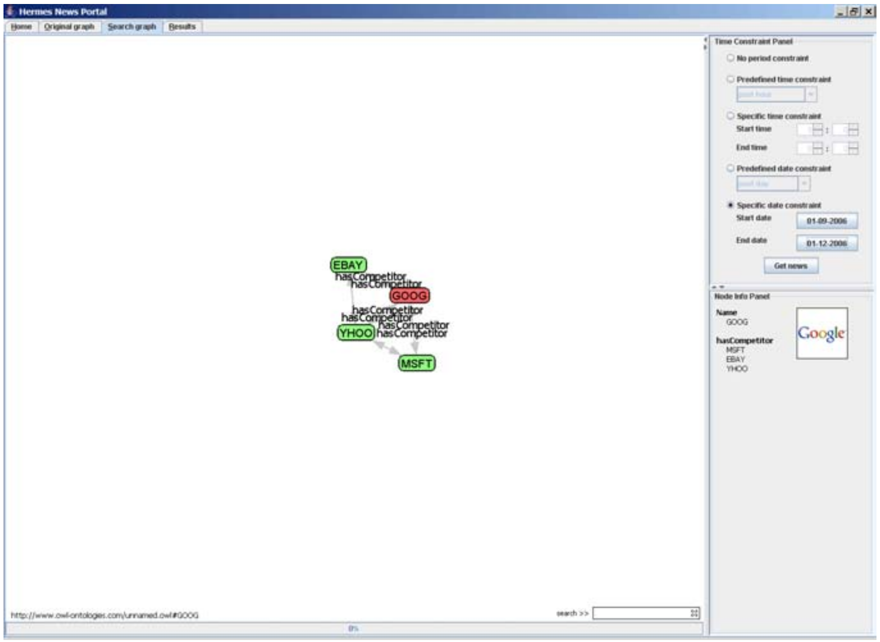
Figure 3 shows the conceptual graph from which the user can select concepts of interest. Once a user selects a concept, the control panel gets activated by means of which the user can add to the search graph his concepts of interest.

The concepts of interest can only be the current concept, all related concepts including the current one, all related concepts excluding the current one, or all related concepts by means of specified relationships including/excluding the current concept. The node info panel shows information regarding the selected concept.

The local name of the different concepts is displayed using ovals. In order to emphasize the different types of concepts we use the following coloring scheme for ovals. The selected concepts are displayed in red, the concepts related to the selected one are shown in green, and the ones returned by the keyword search are presented in pink. The other concepts are displayed in yellow for classes and magenta for individuals.

In the example from Figure 3 the user has directly selected the `Google` concept. In the node info panel all the information related to the `Google` concept is displayed: name, competitors, CEO, etc. Then, the user can select the indirect concepts by specifying the `hasCompetitor`

Figure 4. Search graph example



relationship between the direct concept and the indirect ones. The user also specifies that the `Google` concept should be kept in the search graph.

After selecting the concepts of interest the user can visualize the search graph. The user can refine its query by deleting some of the concepts, resetting the search, or adding new concepts from the conceptual graph to the search graph. After a number of iterations the user has added all the concepts of interests to the search graph.

Figure 4 shows the search graph, which presents the selected concepts, in this case `Google` and its competitors: `Microsoft`, `Yahoo!`, and `EBay`. In the time constraint panel the user can specify the desired time restriction. The user can choose between predefined temporal constraints as the past hour, past day, past week, past two weeks, past three months, past quarter, past half year, and past year, and specific time/date constraints.

As before the node info panel displays information about the currently selected node. However, differently than in the previous situation, only the information given by the specified relationships, in this case the `hasCompetitor` relationship, is displayed.

In this example the user has specified that the news items have to be between 1st of September 2006 and 1st of December 2006, where the current day is 1st of December 2006 (the *last three months* in the user query). Alternatively the user could have selected the past three months option from the predefined temporal constraints.

Query Execution

For each search graph a SPARQL query is generated. This query is a SELECT query as it retrieves the news items in which any of the search graph concepts are present. The disjunctive semantics of the search graph with respect to its embedded concepts is naturally specified as an ‘or’ filter in the SPARQL query. Also, we have decided to use filters to specify the time restrictions that news timestamps need to satisfy. Due to the conjunctive

Figure 5. SPARQL query example

```
PREFIX hermes: <http://hermes-news.org/news.owl#>
SELECT ?title
WHERE {
   ?news hermes:title ?title .
   ?news hermes:time ?date .
   ?news hermes:relation ?relation .
   ?relation hermes:relatedTo ?concept .
   FILTER (
   ?concept = hermes:Google ||
   ?concept = hermes:Microsoft ||
   ?concept = hermes:Ebay ||
   ?concept = hermes:Yahoo
   ) .
   FILTER (
   ?date > “2006-09-01T00:00:00.000+01:00” &&
   ?date < “2006-12-01T00:00:00.000+01:00”
   )
}
```

    xsd:time currentTime()
xsd:dateTime dateTime-add(xsd:dateTime A, xsd:duration B)
xsd:dateTime dateTime-substract(xsd:dateTime A, xsd:duration B)
xsd:duration dateTime-substract(xsd:dateTime A, xsd:dateTime B)
```

Figure 7. tSPARQL query example

```
PREFIX hermes: <http://hermes-news.org/news.owl#>
SELECT ?title
WHERE {
   ?news hermes:title ?title .
   ?news hermes:time ?date .
   ?news hermes:relation ?relation .
   ?relation hermes:relatedTo ?concept .
   FILTER (
   ?concept = hermes:Google ||
   ?concept = hermes:Microsoft ||
   ?concept = hermes:Ebay ||
   ?concept = hermes:Yahoo
   ) .
   FILTER (
      ?date > hermes:dateTime-substract(hermes:now(), P0Y3M) &&
      ?date < hermes:now()
   )
}
```

semantics of the time restrictions we modeled them as an ‘and’ filter in the SPARQL query.

Figure 5 shows the SPARQL query corresponding to the search graph given in Figure 4. This query is hard-coded with XML Schema `dateTime`s specifying the desired temporal boundaries of the interval in which the timestamps of the desired news items need to be contained.

The first part of the SPARQL query defines that the returned news items should be related to the concepts of interest. The second part of the query is composed of two filters. The first SPARQL filter defines the concepts of interest to be `Google`, `Microsoft`, `Ebay`, and `Yahoo!`. The second SPARQL filter specifies that the timestamp of news items should be between 1st of September 2006 and 1st of December 2006, where 1st of December 2006 is the current day. Both dates are specified using XML Schema `dateTime` format.

In order to ease the specification of temporal constraints in queries we have extended SPARQL with custom functions. We call the SPARQL language extended with time functions tSPARQL. Please note that SPARQL does naturally support such extensions, tSPARQL being backwards compatible with SPARQL. Figure 6 shows the signature of the time functions that we have added. These functions relate to retrieving the current `date` and `time`, the current `dateTime` instance, adding/substrating to a `dateTime` instance a `duration`, and subtracting two `dateTime` instances (`date`, `time`, `dateTime`, and `duration` are defined by XML Schema).

Figure 7 depicts the same query as in Figure 5 but now written in tSPARQL. Different than in the previous case the tSPARQL query is not hard-coded with times and dates, but makes use of custom functions and durations. The semantics of the query is closer to its representation, in our current example that is retrieving the news items *that appeared in the last three months.*

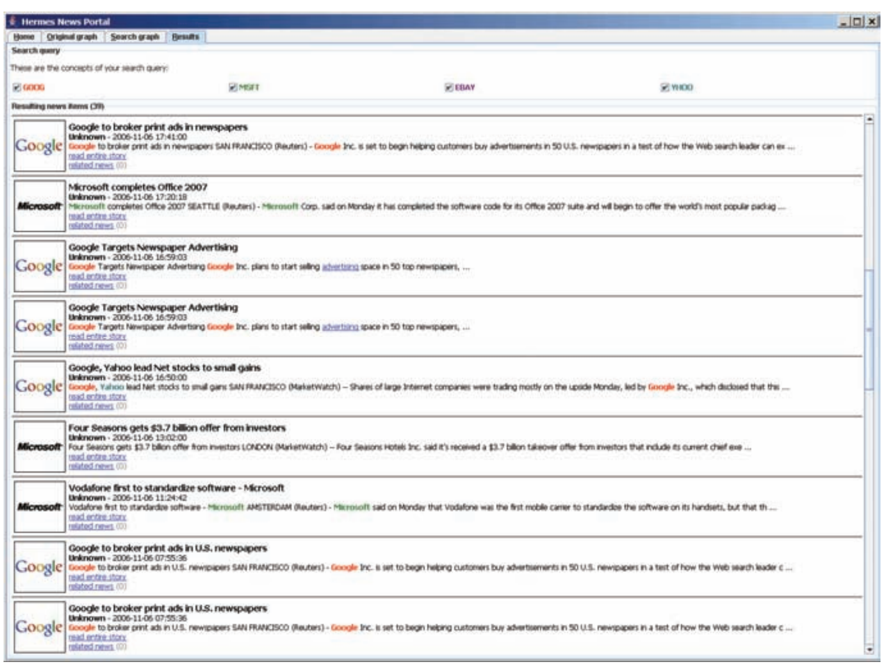
The tSPARQL query uses the `dateTime-substract()` to determine the `dateTime` of three months ago, `now()` is used to obtain the current `dateTime`, and it specifies that the news timestamps should be between these two `dateTimes`. `P0Y3M` is an XML Schema `duration` constant that specifies a period with 0 number of years and 3 months.

After its creation, the tSPARQL query is executed. As a result, the news items that match the query constraints (concepts of interest and temporal constraints) are being returned. The order of the results is not relevant here.

RESULTS PRESENTATION

Figure 8 shows the results after the query execution. It lists the concepts of interest from the search

Figure 8. Results presentation example



graph (top) and the retrieved news items (bottom). In addition, the system shows the found lexical representations of the concepts of interests in the returned news items using different colors. The user is able to deselect some of the concepts of interest in order to refine his query and thus limit the result set. At the current moment the relevance degree and timestamps-based sorting of relevant news items as proposed in the Hermes framework have not been yet implemented in the HNP.

EVALUATION

In order to evaluate the performance of the implementation we measured the concept identification precision. Precision was defined as the number of concepts correctly identified in the news items divided by the number of concepts identified in news items. If we define recall as the number of concepts correctly identified in the news items divided by the number of concepts that should have been identified in the news item, one can notice that for our application precision and recall are the same. The reason is that we are only looking for given concept lexical representation in news items which means that we identify all the concepts that should be recognized possibly with some errors. For our current implementation the precision (recall) is 85% for a given repository of around 200 news items.

Precision (recall) are based on cumulative errors through our application pipeline based on the HNP's part-of-speech recognition, morphological analysis, and word sense disambiguation algorithm. Despite using only WordNet as a semantic lexicon (compared to other approaches which combine several semantic lexicons, some domain specific (Navigli & Velardi, 2005)) we obtained high values for precision as many of our concepts' lexical representations are named entities (names of companies, CEO's, locations, etc.) that usually have only one meaning. The high value of recall can be explained by the fact that we do not aim at providing meaning for each (compound) word in news messages but only for the ones that correspond to lexical representations of ontology concepts. The meanings of the news' (compound) words that are not present in the ontology are used only to help the disambiguation process of found concept lexical representations.

A different metric for the performance evaluation is the latency of a news item in the concept identification phase. The obtained average latency time is around 30s which represents the time needed to process a news item from tokenization to concept recognition. The bottleneck lies in the disambiguation step for which distances between synsets need to be computed. As identified in the Hermes framework these distances can be precomputed (given a certain limit for the shortest path length between synsets) which would further reduce the disambiguation time.

Regarding usability we have asked 9 users (students at Erasmus University Rotterdam following a course on Semantic Web technologies including RDF(S), OWL, and SPARQL) to find news items for 3 given natural language queries in two ways: (1) using the Hermes implementation and (2) a SPARQL engine. Most students were able to correctly build the search graph and specify the temporal constraints, as well as the corresponding SPARQL query. All queries were faster specified using the Hermes framework than using SPARQL. Note that we do not claim that it is easier to use Hermes instead of SPARQL for querying RDF graphs, but for expressing a certain set of RDF queries (the ones supported by the search graph with temporal restrictions, which we consider typical for news querying) Hermes seems to be easier to use than SPARQL. Among the features mostly appreciated by students in Hermes were the graphical representations of the conceptual graph, the predefined time functions, and the visual cues employed for emphasizing concepts in returned news items.

Compared with traditional keyword-based search engines for news items (e.g., YourNews, SeAN, Google News, Yahoo! News, etc.) our semantic approach benefits from better precision, as it is able to disambiguate (compound) words, more query expressive power, because it allows the selection of indirect concepts (i.e., concepts not directly related to the items of interest), and the support for temporal constraints. A quantitative comparison with non-semantic based approaches is difficult to achieve due to the query limitations that these systems have and the impossibility of using the same news items as inputs in the compared systems.

In the tradeoff between expressivity and usability we decided to keep our queries simple with intuitive semantics so that a broad range of users (casual users, media analysts, stock brokers, etc.) should be able to use Hermes. Nevertheless, we acknowledge that an expert user might need more query expressivity (e.g., optional graph patterns, disjunctive semantics for temporal constraints, etc.) which contributes to the increase in complexity (and thus to the decrease in usability) of the framework. For this purpose we plan to extend the Hermes framework in the future with additional powerful functionality that would enable the generation of a news personalization service family (services targeting novice, average, or expert users).

CONCLUSION

The Hermes framework proposes a sequence of steps to be followed for building personalized news services. The input for these systems comprises RSS news feeds and the output are news items fulfilling user needs. The Hermes approach is based on a domain ontology used for classifying news items and to support the user define his concepts of interest. In addition the user can specify temporal constraints that the news item needs to obey. The Hermes News Portal (HNP) is an implementation of the Hermes framework. The domain ontology is specified in OWL and as a query language we used SPARQL. As a semantic lexicon we employed WordNet, one of the most popular English dictionaries available online. For representing temporal constraints we have extended the SPARQL language with temporal functions.

Differently than Google News and Yahoo! News, Hermes is able to exploit the background information stored in ontologies for retrieving user's items of interest. In this way the user doesn't need to explicitly define all the instances involved in the query by making use of the concept relationships for specifying his concepts of interest. In addition to the concepts of interest, the user is able to specify temporal constraints in his query. Another key feature of Hermes is the word sense disambiguation procedure, which is not used in related approaches as SeAN, YourNews, MyPlanet, or SemNews. The word sense disambiguation step increases the accuracy of news classifications, by making sure that the found lexical representations indeed correspond to the meaning of the domain ontology concepts.

As future work, we would like to extend the Hermes framework by employing multiple semantic lexicons and adding specific concepts to the ontology that are not captured in existing semantic lexicons. Some domain specific concepts (e.g., domain neologisms) are used in news items while current semantic lexicons, which are not up-to-date, do not include them. We also plan to exploit the structure of the domain ontology in order to compute the similarity between concepts. In this way we enrich our knowledge base and thus are better equipped in determining concept (synset) similarity.

In addition, we would like to introduce a learning step in which new ontology instances and relations are extracted from news items. For this purpose we envisage the use of lexico-semantic rules that would extract the relevant information from news items. For example a proper noun followed by "Inc." in a news item as in "ClearForest Inc." would indicate that the proper noun is a company which needs to be inserted in the ontology if it is not already present there. In addition we would like to explore the possibilities to redefine the domain ontology as a time-based representation, where instances have a certain time validity associated with them (Milea, Frasincar, & Kaymak, 2008). These temporal extensions to the ontology would enable us to better reason with the temporal contextual information available for our domain.

Another direction that we would like to pursue is that of semantic adaptation of news items based on a user model. The user preferences now represented in the (temporary) search graph would be represented in a (stored) user model which is continuously adapted based on user behavior. In order not to bother the user with already seen content, we would like to be able to filter news items that provide new information by using a novelty control mechanism (Gabrilovich, Dumais, & Horvitz, 2004). We believe that our semantic approach can be successfully applied for modeling dissimilarities between news items and thus be able to recommend only news carrying novel content. In a different scenario, by measuring the similarities between news items, we would be able to recommend news items related to the same story but issued at different moments in time and/or by different institutions.

Regarding HNP we would like to implement news items duplicates removal, and the relevance degree and timestamps-based sorting of relevant news items, as proposed in the Hermes framework. Additionally, we also wish to implement the previously proposed extensions to the Hermes framework: enriching our knowledge sources with multiple lexicons and domain-specific concepts, updating the domain ontology based on news information, adding a user model and employing it to adapt system functionality, and filtering news that provide novel content. Also, we would like to test the usage of data structures for fast data access (e.g., hash maps) for ontology access in a news-centric approach where the concept lexical representations are identified during a single news item traversal. Having a constant access time to concept lexical representations and taking in consideration that the number of lexical representations in a news item is smaller than in an ontology might reduce the time needed for the news classification step.

Additionally, we would like to conduct a more extensive evaluation procedure of the Hermes implementation. Based on detailed questionnaires and measuring the time spent on building queries given in natural language, we can obtain more empirical evidence on the system usability. The accuracy of the proposed relevance degree (based on concept identification) could be determined by measuring the access order and reading time of news item in the result list (accessing the first items first and spending substantial time for reading them are good indications that the returned items are relevant). In addition, we want to experiment with other domains (e.g., politics, sports, etc.) and analyze the precision and latency of our implementation for these new fields. The genericity of our approach only asks for the definition of a new domain ontology and domain-specific news feeds that need to be plugged into our implementation.

ACKNOWLEDGMENT

The authors are supported by the EU funded IST-STREP Project FP6-26896: Time-Determined Ontology-Based Information System for Real Time Stock Market Analysis (TOWL). More information is available on the official website of the TOWL project (TOWL Consortium, 2008). Also, we would like to thank Wouter Rijvordt, Maarten Mulders, and Hanno Embregts for their contribution to the Hermes framework.

ABSTRACT

The Web serves as the principal mediator for information sharing and communication on a worldwide scale. Its highly decentralized nature affords a scale free growth, where each endpoint (i.e., Web site) is created and maintained independently. Web designers and developers have the onus of making sure that users can interact without accessibility problems. However, coping with users with disabilities poses challenges on how to ensure that a Web site is accessible for any kind of user. When (and if) this is done, designers and developers do it in a post-hoc way, (i.e., verify and tweak Web sites according to guidelines such as WCAG). In this Chapter the authors present SWAF, the Semantic Web Accessibility Framework, a base framework for supporting the integration of accessibility services into Web design and development processes. SWAF affords both tailoring accessibility to user needs and specifying the semantic validation of accessibility guidelines in different application situations.

DOI: 10.4018/978-1-60566-650-1.ch003

INTRODUCTION

The increasing adoption of technologies from users puts the Internet in a central spotlight. The Web, as its major application, is accessed and interacted by users at constantly increasing pace, allowing them to quickly seek information, interact with their peers through social networks, or perform transactions from the comfort of their homes. For this reason, the way information is structured and presented is critical for the success of accessing it.

However, users have their own specific characteristics (e.g., abilities, impairments, preferences, knowledge). Consequently, the accessibility of each piece of information – such as a Web page – can differ significantly from user to user. While often dismissed in the Internet realm and, more specifically, on the Web, people with disabilities are not just a small population minority. If one takes into account people with mild disabilities, the slice of the population that requires some sort of software-based accessibility ramp is of the uttermost importance.

The most important way to mitigate this problem is making sure that information providers (ranging from the individual to large corporations) do not overlook such accessibility issues. Internationally recognized organizations such as the World Wide Web Consortium (W3C, n.d.) play a critical role on helping information providers to cope with accessibility. Traditionally, this goes in the form of specifying accessibility-centric best practices, guidelines, and vocabularies to augment already existing Web languages.

Evangelization of accessibility practices, coped with the progressive intertwining of accessibility features in Web languages has brought Web accessibility more close to information providers. Consequently, each day, Web accessibility is gaining awareness. Guidelines such as WCAG, the Web Content Accessibility Guidelines (Chisholm, Vanderheiden, & Jacobs, 1999), are being followed more often, leading more users with disabilities to have access to information without barriers. In order to be so, these guidelines are presented as straightforward as possible, geared towards the largest set of Web designers and developers. However, mostly due to financial, human resources, and technological expertise problems, several companies (and individuals) totally dismiss the adequacy of Web sites to the different requirements of accessibility-dependent audiences, despite the fact that legislation is being pushed in several countries, in order to promote the rights of people with disabilities.

The dismissal of accessibility from information providers leverages the fact that such guidelines and standards for accessibility have inherent problems. Since they are specified in such a way that they require manual inspection of their conformance, developers have an increased effort on coping with accessibility issues. Furthermore, by being informally described (i.e., in natural language), they tend to lead to different interpretations from developers and accessibility experts and, for this reason, different and incoherent ways to ensure that a given Webpage is accessible.

When Webpages and Websites require an additional effort of supporting more specific and fine-grained audiences, the development of accessibility-centric solutions becomes cumbersome. Guidelines have an implicit assumption of which audiences they target to (and more often than not, in a very informal and loose way). Typically, these are often geared towards people with visually impairments (e.g., different kinds of blindness). The way users from this audience interact with a webpage is also left implicit, but often assumed to include specific devices (e.g., screen readers). This leads to a lack of understanding what is the role of guideline checkpoints for each user and device characteristic they are tackling, thus posing more difficulties on developers on how to tackle fine-grained accessibility analysis and consequent development of accessible Websites and Webpages. Consequently, software developers need to have a conceptual framework in which to situate disabled-related guidelines, which they often do not have due to lack of experience with disabled people and their technologies.

This Chapter proposes SWAF (Semantic Web Accessibility Framework) as an ontological framework targeted to accessibility-aware Web design and development processes. This will enable large organizations, small enterprises, or even individuals (developers, designers, etc.) to produce Web sites of superior accessibility and usability, accompanied with appropriate measures, technologies and tools that improve their overall quality. This ontological framework can be used to answer questions about common accessibility standards, user abilities and disabilities, as well as about the technical capabilities and constraints of appropriate assistive devices, thus forming the context for semantic validation of Web accessibility. In This Chapter we present the general overview of the framework, and detail it in the context of existing Web accessibility standards, in order to facilitate accessibility assessment of Web sites across different audiences.

BACKGROUND

Designing for people with disabilities is becoming an increasingly important topic for a variety of reasons, but especially due to recent legislation in many countries that aims at promoting and enforcing the rights of people with disabilities. A number of philosophies and methodologies have been developed to support this process.

Firstly there has been the development of the *universal design*, *design for all*, and *universal usability* philosophies, as detailed by Shneiderman (2000). Many developers worry that they will be expected to produce a system that will be usable by every user, regardless of their abilities, and that they might have to seriously compromise their overall design to achieve this aim. Clearly this would be in no-one's interest. With the increasing ability to personalize interfaces to meet the requirements of different users, this is not necessary.

Secondly, there have been numerous sets of guidelines to help developers produce systems that are accessible and usable by people with disabilities. These range from very general guidelines to the very specific guidelines for Web user agents (e.g., Web browser), authoring tools, and content creators. However, it is not clear whether providing guidelines is an effective method for ensuring usable designs, since these might be differently interpreted by developers and designers. Developers need to have a conceptual framework in which to situate disabled-related guidelines, which they often do not have due to lack of experience with people with disabilities and assistive technologies.

Consequently, even if people with disabilities want to be independent and do things for themselves by themselves, unfortunately, most Web sites and Web applications are not fully accessible today. There are a number of reasons for this as explained below:

- The Web has evolved over the latest years, and the importance of accessibility has only begun to be appreciated and encouraged in recent years. Older solutions are unlikely to be fully accessible (or accessible *at all*). Making an existing Web site accessible is often very difficult and expensive, in much the same way as making an existing building wheelchair-friendly can be very difficult, as well as un-aesthetic. Although efforts should be made to improve accessibility, it will be typically easier to do so during a major refurbishment.
- Many developers and, more surprisingly, designers, are not aware of the importance or need for accessibility. Consequently, new developments are being built in blissful ignorance, as many of them do not have the necessary knowledge or skills for building accessible Web sites.
- Some market stakeholders believe that creating accessible solutions will have prohibited costs and, at the same time, make them boring and less attractive to the majority of users (read: the non-impaired).
- Existing design and development tools give little out-of-the-box assistance in

most cases or, at worst, make it impossible to develop accessible solutions.

Accessibility Standardization

Up to now, there are several initiatives concerning guidelines, tools and technologies for Web accessibility. The major steering body for accessibility is the World Wide Web Consortium and its Web Accessibility Initiative (WAI, n.d.). WAI has three main tracks: the Web Content Accessibility Guidelines (Chisholm et al., 1999), the Authoring Tool Accessibility Guidelines (Treviranus, Richards, Jacobs, & McCarthieNevile, 1999), and the User Agent Accessibility Guidelines (Jacobs, Gunderson, & Hansen, 2002). The activities of W3C and WAI are the result of collaboration of groups and organizations from different countries, like the TRACE Research and Development Centre (TRACE, n.d.), which is responsible for compiling and publishing the original set of Web accessibility guidelines that provided the backbone of WAI guidelines.

Apart from the guidelines, there are also legislative and standards initiatives for accessibility. Strong governmental support in the Unites States has led to initiatives such as the Americans with Disabilities Act (ADA, 1990). The UK equivalent is the Disability Discrimination Act (DDA, 1995) amended in 1999, and now extended to the Special Educational Needs and Disability Act (SENDA, 2001). The rulings of ADA are also extended to Section 508 of the US Rehabilitation Act (Section 508, 1998). This legislation defines processes and the monitoring role of the US federal government in the procurement of electronic and information technology. Regarding accessibility, it states that regardless of medium, government must ensure that disabled federal employees and members of the public have the same accessibility as non-disabled members. Where accessibility is not present, government is directed to provide alternative means. Although, Section 508 is intended for the US federal government, many organizations and software houses worldwide are making efforts to address its mandate, which puts it as a central destination for Web accessibility verification practices.

Major standards bodies such as the US Human Factors and Ergonomics Society (HFES, n.d.) are engaged in furthering the accessibility drive. Their efforts extend to features and functions of the operating systems, drivers, application services, other software layers upon which the application depends and applications that increase accessibility with a general aim of reducing the need for add-on assistive technologies. The International Standards Organisation ISO/TS 16071:2003 (ISO 16071, 2003), Ergonomics of Human–system Interaction also provides guidance on accessibility for HCI interfaces. The guidelines were designed to complement general design for usability covered by related standards on usability.

As thoroughly discussed in this Section, there exist several initiatives and standardization bodies concerning guidelines, standards and methodologies for accessibility assessment that can be effectively applied in the context of Web technologies. It is also a fact that the existing standards and best practices concerning accessibility are in most cases confusing and incomplete (Lopes & Carriço, 2008). Therefore, developers need to have a conceptual framework in which to situate Web accessibility-related guidelines, which they often do not have, due to lack of experience on technologies for the disabled. The fundamental aspect of pushing forward accessibility on Web site design and development practices is to provide concrete and objective rules and standardized guidelines that homogenize accessibility assessment and quality control procedures. Consequently, existing software that aims at assessing accessibility based on such guidelines (a thorough list of such software packages can be found at http://www.w3.org/WAI/ER/tools/complete) will provide incomplete and overly generalized answers to whether a given Web page or Web site is accessible.

While it is clear that determining what truly represents accessibility in the customer's view can be elusive, it is equally clear that the number and frequency of problems and defects associated with a Web site are inversely proportional to its accessibility. Software problems and defects regarding accessibility are among the few direct measurements of software processes and products. Such measurements allow us to quantitatively describe trends in defect or problem discovery, repairs, process and product imperfections, and responsiveness to customers. Problem and defect measurements also are the basis for quantifying several significant software accessibility attributes, factors, user characteristics and criteria.

Although the advantages of measurement in the Web site design and development process are indisputable, the popularity of measurement methods, within accessibility terms, in practice is rather limited (McGarry, 2002; Varkoi, 1999; SEI, 2006). Very often difficulties arise when trying to focus the measurement. In many cases it is unclear what should be measured and also how the measurement data obtained should be interpreted (Habra, Abran, & Lopez, 2004; Kulik, 2000). Choosing the correct measurement entities and ranking the importance of measurement accessibility indicators is still a challenging task (Neely, 1998). Despite the difficulties, metrics such as those defined by Vigo et al. (2007) provide insightful cues on how to approach the problem of measuring the accessibility of Web sites, based on WCAG standards. This will help designers and developers to have a better (and measurable) understanding of accessibility on Web technologies.

Ontologies for Disability and Accessibility

There are several efforts towards the direction of the definition of ontological concepts and taxonomies for people with disabilities. These efforts try to cover adequately the personal requirements of the end users, including the person's disabilities and individual preferences.

A central reference for classifying disabilities concerns the World Health Organization's International Classification of Functioning, Disability and Health (ICF, n.d.), particularly tailored to impairment qualification on medical diagnosis tasks. Consequently, it stresses just on profound disabilities, leaving out several impairments such as color blindness. Obrenovic, Abascal, & Starcevic (2007) have leveraged ICF concepts into an accessibility description framework to help designers and developers discuss and describe multimodal interaction issues.

Gruber (1993) proposes an ontology architecture that tries to cover comprehensively the situation of persons with special needs for the purpose to utilize this information for customization of their home environment's services is proposed. This approach tries to combine contextual information like personal aspects (e.g., disabilities, preferences), technical aspects (e.g., equipment, services, network) and natural aspects (e.g., location, time) in a way that the smart home environment's services can adapt to the end user more or less automatically while keeping the user in control.

Several pre-existed ontologies for supporting context-aware smart environments, like CoOL (Strang, Linnhoff-Popien, & Fank, 2003), COBRA-ONT (Chen, Finin, & Joshi, 2003), CONON (Wang, Zhang, Gu, & Pung, 2004), SOUPA (Chen, Perich, Finin, & Joshi, 2004), and UbisWorld (Heckmann, 2005). All these ontologies share common concepts and structures. From these, SOUPA incorporates most concepts of previously defined ontologies and seems to be the most elaborated one of the listed ontologies. However, all of them still lack a specific support for persons with special needs towards a comprehensive specification.

A major contribution to the field of ontologies for disabilities was made from EU's FP6 ASK-IT project (ASK-IT, n.d.). Within ASK-IT, ontology modeling and mapping produced a collection of shared sub-ontologies, which reflect mobility impaired people user needs, and relationally map available services to them. These needs were initially specified and afterwards, the ontology authoring procedure was based on content models derived from these specifications. It also defines the interrelationships that may rationally hold between user groups of people with disabilities and various user information needs of different content types, including multi-modal content.

The potential for applying ontologies in end user diverse environments and their potential for promoting a unified methodology is exemplified by the ontology devised by Uschold, King, Moralee, & Zorgios (1998). This ontology includes lexical and relational terms based on the idea of the activity (anything that involves doing) linked to the doer or operative unit which may be a person, organizational-unit or machine said to have capability and on occasion possessing roles in respect of an activity such as activity-owner.

Wooldridge, Jennings, & Kinny (2000) also adopted a role-oriented analysis as a natural step in the Gaia methodology. Another example, the Framework for Distributed organizational Memories (Abecker et al., 2001), describes the various actors in domain ontologies according to their goals, knowledge and competencies. Van Heijst, Schreiber, & Wielinga (2000) also capture the role of an ontology in the accessibility requirements specification process, where they illustrate how a methodology can extract semantics from an ontology at different levels of depth to produce conceptual models.

As stated by Masuwa-Morgana & Burrell (2004), an ontology for accessibility requirements could be centered in a similar fashion, on an activity such as a use case in which there are doers (people and access technologies). The only difference is that in that ontology for accessibility requirements there would be a need to reliably furnish (with clear identities and essence) descriptions of doers-people and patterns of doer-access technology and subsequent competencies and demands on interface design and interaction styles. Abecker et al. (2001) propose "AccessOnto" as an accessibility requirements theoretic ontological framework consisting of four components: a requirements elicitation subsystem, an inference engine, a requirements explanation subsystem and an accessibility knowledge base. It has the intention of extrapolating a requirements specification based on rules extracted from the accessibility knowledge database based on end user traits data elicited by the end user.

The aforementioned ontological frameworks emphasize the fact that there is little coupling between ontologies regarding accessibility and disabilities, and Web accessibility assessment practices (as they tend just to frame different accessibility scenarios). Our proposed ontological framework will be based on existing ontological models, as well as in best practices for ontology engineering, affording the design of a multi-layer knowledge base for accessibility and disability requirements mapping into Web accessibility verification procedures that can provide support for the requirements and needs of different accessibility-centric user groups.

SEMANTIC WEB ACCESSIBILITY FRAMEWORK

For many people, in particular for groups at risk of exclusion, the complexity and lack of accessibility and usability of Web sites is a major barrier to information access. We respond to this challenge by proposing a tailored accessibility assessment ontological framework, the Semantic Web Accessibility Framework (*SWAF*), which affords the specification of user characteristics and their requirements, and associate them to specific accessibility assessment procedures.

The main goal of SWAF is to provide support for the formal and unambiguous definitions of accessibility domains, as well as the possible semantic interactions between them. We have specified SWAF to be integrated into accessibility verification environments (e.g., authoring tools, Web accessibility evaluators, integrated development environment - IDE). This will establish a common vocabulary for exchanging and describing the complex information that is related to accessibility assessment of Web sites. The framework aims to formalize conceptual information about:

- The *characteristics* of users with disabilities, devices, applications, and other aspects that should be taken into account when describing an audience with disabilities and developing tailored Web sites.
- Web accessibility *standards* and associated checkpoints.
- Semantic *verification rules* to help describing requirements and constraints of audiences, and associating them to accessibility checkpoints.

In order to cope with these goals, the framework must comply with the following requirements:

- To be as *formal* as possible, thus providing all the necessary definitions in a concise, unambiguous, and unified form;
- Provide information that can be *easily processed* by software applications and integrated into accessibility validation processes;
- *Easily implemented* by software developers and other users involved in the software development process of Web accessibility tools.

One of the main issues in designing and developing the proposed framework was to make it maintainable and extensible, while assuring model consistency within the framework. Therefore, we have separated SWAF into two distinct dimensions: *Web Accessibility Descriptions*, and *Web Accessibility Mapping*, as depicted in Figure 1. Each dimension is further explained in the following Sections.

Web Accessibility Descriptions

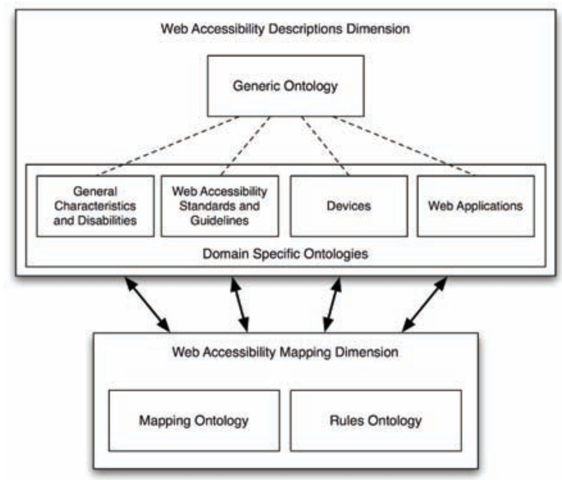
The first dimension provides constructs to describe different Web accessibility concepts (WAD). To explore the differences and synergies between Web accessibility fields, and to support the inclusion of external concepts from other domains, the WAD dimension cuts the concept space into a Generic ontology and a set of Domain Specific ontologies, as detailed next.

Generic Ontology

The Generic ontology forms the core ontology and describes top-level entities and concepts that are critical for the semantic validation of Web accessibility. Thus this ontology provides more abstract and generic knowledge such as general characteristics and disabilities of users, devices, Web accessibility standards, and other main aspects that constitute the basis for applying accessibility-based approaches into the accessibility validation field.

Domains are specified in classes and subclasses providing a hierarchical model representing all the knowledge fields that are necessary for the accessibility validation. There are also a number of properties denoting the relationship between classes. A part of the Generic Ontology is depicted in Figure 2. This partial snapshot of the ontology consists of the main classes *Disabilities*, *WAI_WCAG* and *Devices*. The *Disabilities* class contains three subclasses: *HearingImpairment*, *SpeechImpairment*, and *VisualImpairment*. There is also a property of the type *hasIncludedDomains* denoting that the classes *WAI_WCAG* and *Devices* include disabilities.

Figure 1. Semantic Web accessibility framework

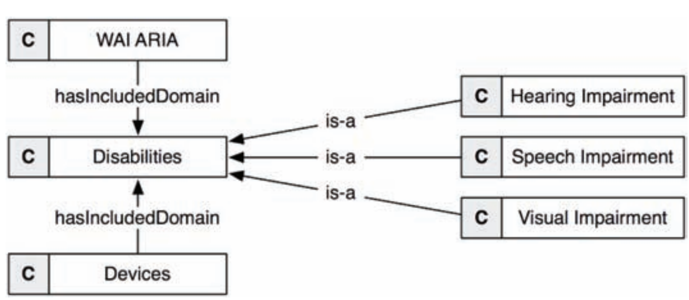


Domain Specific Ontologies

To better illustrate how the Generic Ontology can cope with real scenarios within the Web accessibility domain, we defined several domain specific ontologies and integrated them into SWAF. These domain specific ontologies (DSO) cope with the key aspects that are part of the integration of Web accessibility into Web design and development processes. This way, ontologies are able to represent a more detailed description of their corresponding domain, fruitful for extensibility scenarios (e.g., using Web accessibility validation ontologies in Mobile Web tailoring scenarios). The purpose of distinguishing a generic ontology from the domain specific ones is to facilitate the extension of SWAF to different application domains (e.g., outside the scope of Web related accessibility guidelines and applications).

Each DSO uses the basic entities of the Generic Ontology to describe the specific concepts and structures that are needed for the semantic validation of Web accessibility. This ensures that all terms and their relationships utilized by each accessibility approaches separately are included in the generic ontology scheme. To cover every spectrum of applicability of accessibility assessment procedures, there should exist a corresponding domain specific ontology. Next, some of these ontologies are described.

Figure 2. Excerpt of the generic ontology



General Characteristics and Disabilities Ontology

As discussed previously, validating accessibility is a process that must cope with user's disabilities, as well as with each individual's preferences. Thus it is of great importance to consider the users' personal capabilities determined by her/his impairments. Consequently, different categories of disabilities (based on the ICF categorization) are incorporated within this ontology, such as:

- *Visual impairments*. Disorders in the functions of the eye ranging form reduced capability of sight, color-blindness to total disability to see (e.g., cataracts or retinal detachment).
- *Hearing impairments*. Disorders in perceiving audio, ranging from problems in understanding normal conversations to complete deafness (e.g., high or low tone hearing loss).
- *Specific learning impairments*. Disorders manifested by significant difficulties in the acquisition and use of listening, speaking, writing, reading, reasoning, or mathematical abilities.

The degree of the users' disabilities determines the extent of Web accessibility concepts and guidelines that must be followed by Web sites (e.g., enlarging font sizes) to suit to users' computing environment and usage context.

To afford the specification of such concepts, the General Characteristics and Disabilities Ontology provides a set of supportive constructs at a meta-level (e.g., generalizations). The main concepts are *User* and *Characteristic*. A *hasCharacteristic* property maps characteristics to users, thus affording the description of users. We have further detailed several meta-concepts under the *Characteristic* umbrella. Since this ontology is tailored to accessibility scenarios (in the broad sense of *ability to access*), we introduced a small taxonomy to afford the classification of *Characteristic* instances. This taxonomy distinguishes *Ability*, *Disability*, and *Preferences*, as well as more specific concepts (e.g., *SensorialAbility* or *LearningDisability*). Accordingly, the *hasCharacteristic* property has been refined to cope with the three main domains.

Lastly, to afford a semantic extensibility and proper categorization of user characterization concepts, we defined an *extendsCharacteristic* property that maps between *Characteristic* instances in a taxonomical way.

All of these concepts provided by the ontology strive for a strong and expressive tool for Web designers and developers to describe and characterize their target users in a clean, thorough way, along the line of the descriptive ontologies devised by Obrenovic et al. (2007). Furthermore, by affording an extensible way of organizing user characterization concepts independently from users/audiences, Web designers and developers can build their own taxonomies with respect to their particular needs without being tied to a particular way of thinking and organizing information typical of stricter solutions.

Web Accessibility Standards and Guidelines Ontology

This domain ontology covers the main evaluation guidelines for Web accessibility assessment devised in the Web Accessibility Initiative, such as WCAG. These guidelines are divided into checkpoints and arranged based on their impact and priority. The combination of these factors is given in levels (none, A, AA, or AAA), depending on their evaluation outcomes. For instance, to claim conformance on level A, all the priority one checkpoints must be satisfied.

The table presented in the Appendix of this chapter reproduces the most fundamental Priority 1 checkpoints, which have been incorporated into this ontology. It is important to notice that some of these checkpoints may be irrelevant in different situations. Certain Web site instances might not have markup that can trigger accessibility problems. Furthermore, they might also be irrelevant based in the particular constraints and preferences of a user (from an accessibility point-of-view).

In particular, the checkpoints 1.2 and 9.1 apply (only) if image maps are used, the checkpoints 5.1 and 5.2 apply if tables are used, the checkpoint 12.1 applies if frames are used, the checkpoint 6.3 applies if applets or scripts are used, and finally the checkpoints 1.3 and 1.4 apply if multimedia is used. Most of these checkpoints are just relevant for those with visual impairments.

On the meta-level, this ontology introduces the *Guideline* and *Checkpoint* concepts, which can be mapped through an *includesCheckpoint* property. While Web designers and developers can leverage verification processes with the already supplied instances for WCAG, the extensibility provide by this meta-level affords the addition of new guidelines and checkpoints to their development processes in an effective way. Furthermore, this will allow them to leverage out-of-the-box all domain independent verification rules provided in SWAF's Web Accessibility Mapping Dimension.

Devices Ontology

Owing to the rapid development of electronic technologies, it tends to be common to access Web sites outside the traditional field of a desktop PC and a computer screen (e.g., PDAs, mobile phones, assisting devices, etc.). This has brought more specific assistive technologies to improve interactivity for users with disabilities, as well as broad personal preferences. This includes the ability of coping with diverse input/output modalities combination within interactive scenarios. Since the diversity of these technologies varies along different axes (e.g., display resolution, images coloring, multimedia process, etc.), the way accessibility is assessed for Web pages must also cope with these differences.

This ontology provides a simple set of meta-level concepts to describe devices ecology: a *Device hasFeature DeviceFeature*. Like in the description of users and accessibility scenarios, this ontology affords out-of-the-box instances for common cases of devices and device characteristics without closing the door to extensibility and odd-case scenarios.

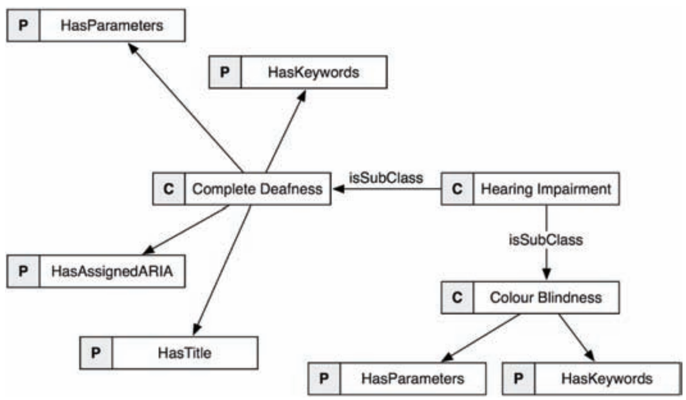
The description of devices can be used at two different fronts within development processes: it can help triggering semantic validation rules on user/device mismatches (e.g., user with total blindness and computer screen), and tying Web accessibility guidelines and checkpoints to particular devices and/or device features.

Web Applications Ontology

Web pages are not the only end for Web technologies. Nowadays, an increasingly number of applications is being ported from "traditional" desktop environments into Rich Internet Applications (RIA), by taking advantage of the richness of Web browsers, thus becoming easily available to any kind of users. However, since these technologies cannot cope with specific semantics of desktop applications widgets, accessibility issues may arise. The proposed domain ontology supports the development of accessible Web applications by affording the inspection of ARIA keywords (Accessible RIA) within Web pages, according to application requirements.

Figure 3 represents a partial snapshot of the ontology describing the knowledge domain of *HearingImpairment*. One of the main classes is the *CompleteDeafness* that consists of four subclasses *Title*, *Parameters*, *Keywords* and *AssignedARIA*. Each of these subclasses is characterized by a set of properties that can be either a simple data property or an object property that denotes the relationship between two classes.

Figure 3. Example of domain description ontology



This ontology supports both HTML-specific concepts (such as key HTML terms that have influence on accessibility issues), besides Web application domain concepts. This way, Web pages are perceived as a subset of Web applications from the point-of-view of key concepts, thus affording reuse scenarios of the ontology.

For example, the Web Applications Ontology provides the *GUICharacteristic* and *GUITechnology* abstract concepts (coupled with more fine-grained concepts such as *HTML*), to support the description of the Web Applications domain.

Web Accessibility Mapping

Finally, SWAF is completed with the Web Accessibility Mapping (WAM) dimension. This dimension aims to cover the establishment of mapping relationships between the ontologies of the first dimension, and to validate the semantics of these relationships. These relationships can be used, e.g., for efficient navigation and searching inside the ontologies, as well as to afford the creation of semantic rules-based accessibility verification. Two ontology layers are provided in this dimension (as detailed next): *Mapping Ontology*, and *Rules Ontology*.

Mapping Ontology

The WAM dimension provides a mapping ontology comprising of a set of lexical and notational synonyms to express the semantics of the relationships between concepts within the *General Ontology* and *Domain Specific Ontologies*. This mapping is necessary, since each ontology domain represents the semantics of different knowledge domains. It is important to notice that these mapping concepts can be use to tie terms from the General Ontology to any Domain Specific Ontology, as well as between different Domain Specific Ontologies. This way, the Semantic Web Accessibility Framework can support different interdependent relationships between DSOs, thus affording richer Web accessibility validation scenarios.

Since the proposed integration needs require that information be passed seamlessly among the different layers, generic and domain ontology mapping is absolutely necessary. This semantic information stems from the semantic metadata description of the content and has to be mapped to the corresponding classes and properties of the relevant domain description ontology. Therefore, each domain specific ontology will provide a set of concepts to the mapping ontology to support this type of mappings.

For instance, the Web applications ontology provides properties to map *Checkpoint* instances (inherent from the Web Accessibility Standards and Guidelines Ontology) to *Application* instances (described with concepts from the Web Applications Ontology). This mapping property allows the specification of which checkpoints are valid to the particular set of technologies available for the design and development of Web applications. Another set of mapping concepts provide support for bridging *Checkpoint* instances with *Device* instances and *User* instances, thus closing the loop between characterization of devices and audiences and tailored Web accessibility assessment processes.

Rules Ontology

The last piece in the Web Accessibility Mapping dimension of the Semantic Web Accessibility Framework concerns the specification of semantic validation rules for Web accessibility. This ontology will provide the required set of rules that go beyond the syntactic analysis of Web accessibility processes, such as the description of checkpoints, users, etc. The role of this ontology is, therefore, to bridge the semantic verification gap between the Web Accessibility Description domain and the Mapping Ontologies.

We have devised this ontology as a set of rules based on SWRL (Horrocks, Patel-Schneider, Boley, Tabet, Grosof, & Dean, 2004), a rules language that affords the specification Horn-like rules with OWL predicates. The Rules Ontology can be used to reason which concepts from other ontologies (both at the instance and meta levels) and which combinations of them are satisfied by accessibility validation procedures. By setting up these rules within an inference engine, relevant accessibility rules will be reasoned out according to the information residing within the ontologies of the Semantic Web Accessibility Framework's Web Accessibility Domain dimension.

While some rules can be specified with General Ontology concepts, its use is fairly limited, as they are not tied to particular application domains. By using terms originated from Domain Specific Ontologies, and by combining them according to the semantics of existing validation processes, Web design and development processes can be augmented with more interesting verification rules that are triggered according to specific application/audience requirements. It is worth mentioning the fact that this ontology serves as an entry point for semantic validation processes. We devised it as a placeholder upon which the SWAF ontology can (and, in fact, *should*) be enriched with application-specific and technology-specific semantic Web accessibility validation rules.

As a simple example, we present the description of a set of rules for users that have been characterized as having some sort of visual disability, and how to cope with content presentation. This is one of the critical rule types that are to be supported within Web accessibility validation scenarios. User rules are defined as the set *UR* = {*U1*, *U2*, *U3*}, where each one of the rules represents a single semantic validation according to a specific user audience:

U1: if user is color blind then content of black and white images and black text are preferred.
U2: if user is partially sighted then content of audio and appropriate image is preferred.
U3: if user is totally blind then pure audio content is preferred.

The same approach can be used in other domains, e.g., for devices. When verifying if Web sites can cope with device capabilities, one can check if content can be appropriately fit into the constraints imposed by devices. Such rules domain, e.g., DR = {*D1*, *D2*, *D3*} can be defined as:

D1: if device is a mobile phone then image depth must be black and white.
D2: if device is a PDA image color contrast must be high.
D3: if device is a PC then image depth can be of any size.

When defining such semantic rules, the constructs available on the different ontologies can be used to express the concrete situations that help Web designers and developers in the tailored Web accessibility verification processes in an effective, unambiguous way. As an example, we detail how to express the Checkpoint 2.1 from the Web Accessibility Content Guidelines 1.0 (as shown in the Appendix), which state: "Ensure that all information conveyed with color is also available without color, for example from context or mark-up". When targeting to audiences composed by individuals with color blindness, this checkpoint can be expressed in SWRL as (compact syntax):

```
wao:hasGUITechnology(?APP, ?x1)
&
wao:HTML(?x1) &
wao:hasGUICharacteristics(?x1,
?x2) &
wao:characteristicName(?x2, "al-
ternativeNonColoredInformation")
&
wao:characteristicValue(?x2,
"true") &
gdco:hasDisability(?USER,
Individual("colorBlindness"))
=>
wasgo:isDefiningValidApplica
tion(Individual("WAI_check-
point2.1"), ?APP)
```

Here we are ensuring that conforming to Checkpoint 2.1, only for users (?USER) characterized by color blindness (colorBlindness), applications (?APP) encompassing HTML technologies (wao:HTML) must provide alternative non colored information. It is worth mentioning that the constructs provided by the Web Accessibility Ontology (wao:hasGUITechnology, wao:HTML, wao:hasGUICharacteristics, wao:characteristicName, and wao:characteristicValue) form the core validation rule, since they bind more general concepts (color blindness, WCAG checkpoint) to concrete concepts inherent of the application domain. All of these concepts would have to be substituted, if targeting the specific WCAG rule to other application technology (e.g., outside the scope of Web accessibility). Likewise, this type of rule can be easily adapted to device constraints such as the device domain rules described above, as follows:

```
wao:hasGUITechnology(?APP, ?x1)
&
wao:HTML(?x1) &
wao:hasGUICharacteristics(?x1,
?x2) &
wao:characteristicName(?x2, "al-
ternativeNonColoredInformation")
&
wao:characteristicValue(?x2,
"true") &
do:hasFeature(?DEV,
Individual("colorDepth1bit"))
=>
wasgo:isDefiningValidApplica
tion(Individual("WAI_check-
point2.1"), ?APP)
```

Here we attach Checkpoint 2.1 just to those devices (?DEV) that are severely constrained by color depth, e.g., just black and white displays ("colorDepth1bit"). All other atomic rules can be retained, thus showing that Web accessibility verification semantics are similar between different characterization and verification domains (e.g., color blind vs. color depth). In both rules, the test for alternativeNonColoredInformation provides the bridge towards an actual accessibility check. In this case, a software component attached to a SRWL rules processor is triggered and analyses an HTML document accordingly.

More complex rules can be built on simpler rules, thus affording sharing semantics between verification scenarios. This will afford a richer and more complete approach to the implementation and integration of SWAF into Web accessibility aware design and development tools. In the next example we rework the two rules presented above by refactoring the common set of rules in a modular way:

```
wao:hasGUITechnology(?APP, ?x1)
&
wao:HTML(?x1) &
wao:hasGUICharacteristics(?x1,
?x2) &
wao:characteristicName(?x2, “al-
ternativeNonColoredInformation”)
&
wao:characteristicValue(?x2,
“true”)
=>
ex:verifyHTMLColor(?APP)
ex:verifyHTMLColor(?APP) &
gdco:hasDisability(?USER,
Individual(“colorBlindness”))
=>
wasgo:isDefiningValidApplica
tion(Individual(“WAI_check-
point2.1”), ?APP)
ex:verifyHTMLColor(?APP) &
do:hasFeature(?DEV,
Individual(“colorDepth1bit”))
=>
wasgo:isDefiningValidApplica
tion(Individual(“WAI_check-
point2.1”), ?APP)
```

FUTURE TRENDS

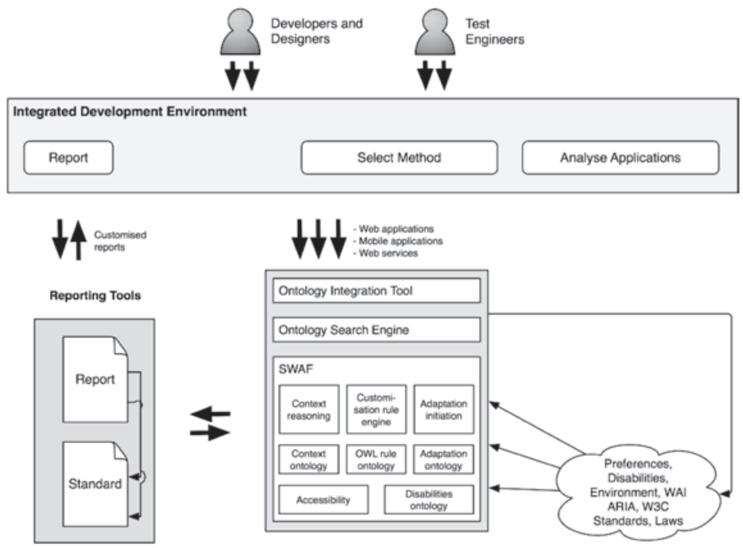
As described earlier, Web accessibility is gaining traction as time goes by, and as Web technologies mature. Web designers and developers are becoming more receptive to accessibility and inclusive design practices, to broaden the spectrum of users that can be targeted by a Web site or Web application. Still, they tend to follow blindly guidelines such as WCAG, thus lacking the perception that these do not cope with a high range of accessibility situations that are not taking into account.

Furthermore, the lack of integration of accessibility tools within the design and development process of Web sites and Web applications tend to leave accessibility assessment procedures to quality assurance tasks or, at best, usability testing tasks. This fact sets Web accessibility assessment as a patch to existing development processes, which has consequences on the adequacy of Web sites and applications.

We believe that the entry point for disrupting how Web accessibility is perceived nowadays must come from proper tool support, e.g., by means of open and free Web accessibility tools that can be plugged into existing Integrated Development Environments (e.g., NetBeans, Visual Studio, etc.) and design tools (e.g., Dreamweaver). This way, Web designers and developers will have an acute sensibility for Web accessibility issues during the design and development processes they are working in.

As an extra point, the Semantic Web Accessibility Framework detailed in this Chapter provides a fine-grained control of audiences and their characteristics, and how these can cope with existing Web accessibility guidelines. We expect that by providing this feature out-of-the-box, Web design and development teams will bring audience-modeling procedures to their development processes. This will give them more control on implementing Web sites and Web applications that are accessible and verifiable during development stages.

Figure 4. Architecture for accessibility validation services



Lastly, while Web accessibility is an important issue to take into account, it is just the starting point for providing digital services to end-users that are totally accessible and universally usable. Other domains, such as mobile phones, desktop applications, or even embedded services must also be targeted by accessibility assessment procedures during early design and development stages. The SWAF framework described in this Chapter will be extended in the future to cope with these scenarios in a very effective way, since extensibility is one of the core concerns inherent to it. On Figure 4 we present our vision of the application of SWAF in the context of application development (not just to Web sites and Web applications), and how it can be tied to Integrated Development Environments.

This architecture builds on the core technologies and concepts defined in SWAF in different fronts. First, different application domains are supported through a plug-in fashion (e.g., Web accessibility would be one of the plug-ins), based on semantic technologies such as the Mapping and Rules ontologies, or the General Characteristics and Disabilities ontology. An inference engine would provide context-reasoning features tied to particular application and technology-dependent ontologies (e.g., Web sites and HTML). We envision three extra components in this architecture that complement SWAF: (1) an ontology-oriented search engine, where developers can search for information residing in SWAF-based knowledge bases, (2) an ontology integration tool, to afford the specification of new domain-specific ontologies, and (3) a set of reporting tools centered on providing concise information about accessibility assessment procedures.

A supportive Integrated Development Environment will tie these technologies to already existing features as a complementary facet of development (e.g., similar to a debugging/helper feature). We believe that enriching IDEs with such features, as well as supportive accessibility simulation and reporting facilities will bring Web accessibility and general accessibility assessment procedures to a wide range of designers and developers, thus lowering the burden of providing accessible applications to all users without any kind of barriers.

CONCLUSION

This chapter presented SWAF, the Semantic Web Accessibility Framework, as the foundation for the semantic description of Web accessibility audiences, concepts and verification rules. This framework provides the basic constructs for the creation of Web accessibility verification engines that are capable of performing assessments tailored to specific user audiences and interaction devices. We have divided SWAF into two dimensions, Web Accessibility Descriptions (which includes general and domain specific concepts) and Web Accessibility Mapping (which affords semantic mapping and rules between concepts from the first dimension), in order to afford the extension of SWAF into different domains in the scope of Web accessibility.

Ongoing work is currently being done in several fronts in the SWAF realm, including: (1) building a comprehensive set of concept instances for user and device feature characterization, (2) providing support for guidelines and standards other than WCAG, (3) improving the Mapping Ontology to cover more situations, (4) implement a robust inference engine supporting SWAF concepts, (5) integrate this inference engine into existing Integrated Development Environments and other Web site development tools, and (6) extend the SWAF ontology to cover other application domains outside the scope of the Web.

KEY TERMS AND DEFINITIONS

Accessibility: The *ability to access*. Often tied to people with disabilities (e.g., total blindness), accessibility thrives to break the barriers to information access. We follow the strict sense of accessibility by embracing any situation where the ability to access information can be disrupted by device or even surrounding environment constraints.

Accessibility Guidelines: A set of best practices that must be followed by designers and developers when implementing software solutions (e.g., Web site) that will help on providing accessible information. By being guidelines, it should not be assumed that content is accessible just by following them.

Checkpoint: A concrete verification task that materializes a (part of a) guideline. Checkpoints can be fully automated if application technology provides corresponding support (e.g., verifying if all images have associated textual captions).

Integrated Development Environment: A computer application used by developers that provides several features to ease the task of developing applications, such as text editor, compiler, automation features, etc.

Universal Usability: a research field that studies the adequacy of user interfaces and information to all users, regardless of their characteristics, knowledge, or mean of interaction (Shneiderman, 2000).

Usability: A research field that studies how adequate user interfaces are to users, how easily can they learn to perform tasks, and what are their levels of satisfaction when interacting with user interfaces.

User Interface: The "visible" side of an application, where users can acquire and interact with information.

Web Accessibility: The subfield of accessibility that is targeted to the specific technologies and architecture that compose the World Wide Web. This includes technologies such as HTML, CSS and JavaScript, as well as the HTTP protocol.

APPENDIX

Table 1. WAI Web Content Accessibility Priority 1 Checkpoints

Cp	Description
Cp1.1	Provide a text equivalent for every non-text element (e.g., via "alt", "longdesc", or in element content).
Cp2.1	Ensure that all information conveyed with colour is also available without colour, for example from context or mark-up.
Cp4.1	Clearly identify changes in the natural language of a document's text and any text equivalents (e.g., captions).
Cp6.1	Organize documents so they may be read without style sheets.
Cp6.2	Ensure that equivalents for dynamic content are updated when the dynamic con-tent changes.
Cp7.1	Until user agents allow users to control flickering, avoid causing the screen to flicker.
Cp14.1	Use the clearest and simplest language appropriate for a site's content.
Cp1.2	Provide redundant text links for each active region of a server-side image map.
Cp9.1	Provide client-side image maps instead of server-side image maps except where the regions cannot be defined with an available geometric shape.
Cp5.1	For data tables, identify row and column headers.
Cp5.2	For data tables that have two or more logical levels of row or column headers, use mark-up to associate data cells and header cells.
Cp12.1	Title each frame to facilitate frame identification and navigation.
Cp6.3	Ensure that pages are usable when scripts, applets, or other programmatic objects are turned off or not supported. If this is not possible, provide equivalent information on an alternative accessible page.
Cp1.3	Until user agents can automatically read aloud the text equivalent of a visual track, provide an auditory description of the important information of the visual track of a multimedia presentation.
Cp1.4	For any time-based multimedia presentation (e.g., a movie or animation), synchronize equivalent alternatives (e.g., captions or auditory descriptions of the visual track) with the presentation.
Cp11.4	If, after best efforts, you cannot create an accessible page, provide a link to an alternative page that uses W3C technologies, is accessible, has equivalent in-formation (or functionality), and is updated as often as the inaccessible (original) page.

Chapter 2.16
Building Semantic Web Portals with a Model-Driven Design Approach

Marco Brambilla
Politecnico di Milano, Italy

Federico M. Facca
Leopold-Franzens-Universität Innsbruck, Austria

ABSTRACT

This chapter presents an extension to Web application conceptual models toward Semantic Web. Conceptual models and model-driven methodologies are widely applied to the development of Web applications because of the advantages they grant in terms of productivity and quality of the outcome. Although some of these approaches are meant to address Semantic Web applications too, they do not fully exploit the whole potential deriving from interaction with ontological data sources and from semantic annotations. The authors claim that Semantic Web applications represent an emerging category of software artifacts, with peculiar characteristics and software structures, and hence need some specific methods and primitives for achieving good design results. In particular the contribution presented in this chapter is an extension of the WebML modeling framework that fulfils most of the design requirements emerging in the new area of Semantic Web. The authors generalize the development process to cover Semantic Web needs and devise a set of new primitives for ontology importing and querying. The chapter also presents a comparison of the proposed approach with the most relevant existing proposals and positioned with respect to the background and adopted technologies.

INTRODUCTION AND MOTIVATION

Modern Web applications comprise distributed data integration, remote service interaction, and management of workflow activities, possibly spawned on different peers. In this scenario, a wider attention to the semantics of data and applications is mandatory to allow effective design and evolution of complex systems. Indeed, if semantics of data and applications is known, their integration becomes more feasible. Moreover, explicit semantic annotation of Web applications can facilitate content search and access, and foster a future generation of Web clients that exploit the semantic information to provide better browsing capabilities to customers.

The Semantic Web aims at bringing formal “semantics” to the human-readable information so as to make it machine-readable and allow better and easier automatic integration between different Web applications. To address this challenge, many semantic description languages arose, like RDF, OWL and WSML; some of them are currently W3C Recommendations. All these languages allow to formally model knowledge by means of ontologies: the resulting formal models are the starting point to enable easy information exchange and integration between machines.

These languages are suitable for reasoning and inference, i.e., to deduct more information from the model by applying logical expressions. This makes the modeling task easier since not all the knowledge has to be modeled. These languages are supported by a wide range of tools and APIs, that cover design of knowledge (e.g., Protégé (Noy et al., 2001) and OntoEdit (Sure et al., 2002)), provide storing facilities (e.g., Sesame (Aduna, 2007) and Jena (HP, 2007)), and offer reasoning on the data (e.g., Racer (Racer Systems, 2007) and Pellet (Sirin et al.,2007)). Based on these modeling languages, a set of querying languages have been devised too; among them, we can mention TRIPLE (Sintek & Decker, 2002) and SPARQL (W3C, 2007), a W3C candidate recommendation.

Unfortunately, although the theoretical bases and some technological solutions are already in place for Semantic Web support, the techniques and methodologies for Semantic Web application design are still rather rough. This leads to high costs of implementation for Semantic Web features, even if embedded within traditional Web applications. These extra costs are related not only to the design of the architecture and deployment of the Semantic platforms, but also to the repetitive and continuous task of semantic annotation of contents and application pages.

We claim that conceptual modeling and model-driven development can increase dramatically the efficiency and efficacy of the design and implementation of such applications, by offering tools and methodologies to the designer for specifying semantically-rich Web applications.

The model-driven approach to software development has been proven valid in several application fields and is currently one of the best practices of the software engineering discipline. Developing a Semantic Web application, as with any other kind of software system, is a complex achievement that requires the ability to master a broad spectrum of tasks, jointly performed by a number of persons with different skills for a long timeline. Software engineering and Web engineering (Ceri et al., 2002) demonstrated that following a well organized development process, centered on the appropriate modeling concepts, is essential to overcome the complexity inherent to such kind of developments.

This chapter aims at demonstrating how model-driven design can impact on specification, design, and implementation of Semantic Web portals as well. In the proposed approach, we leverage a conceptual modeling approach for visually designing the Web application domain model and hypertext model. Conceptual modeling works at higher abstraction levels with respect to direct implementation design, thus allowing to specify the application design with a top-down philosophy. The first design steps aim at describing the platform-independent domain and hypertext models, disregarding the low-level details. Further refinements can take more and more into account such details, finally leading to the expected outcome of the work. These approaches take great advantage from the adoption of C.A.S.E. (Computer Aided Software Engineering) tools, which provide facilities for designing and implementing applications according to specific methods and notations. C.A.S.E. tools sometimes include partially or completely automatic code generation too.

As a concrete example of modeling language, we pick WebML (Web Modeling Language) (Ceri et al., 2002), a well known methodology and set of metamodels in the Web engineering environment, and its companion C.A.S.E. tool WebRatio (WebModels s.r.l., 2007).

To discuss our approach and related background technologies, a running example will be used throughout the chapter. We discuss a realistic scenario based on the reuse of existing ontologies available on the Internet that can be easily exploited to create new Semantic Web Portals. In particular, we will consider two ontologies for the musical domain to build a Web application offering access to music contents, considering also users profile information. We combine the MusicBrainz ontology (http://www.musicbrainz.org) for the music domain information; the MusicMoz (http://www.musicmoz.org/) hierarchy to classify music genres; the RDF Site Summary (RSS-DEV Working Group, 2000) for music news; and the Friend Of A Friend (Foaf) ontology (Miller & Brickley, 2000) to describe for user's profiles and relationships among them. The case study application is similar to other existing Semantic Web applications (e.g., http://Foafing-the-music.iua.upf.edu/, http://squiggle.cefriel.it/music/), that provide personalized access to the contents exploiting distributed semantic information. The presented application, although rather simple because of space reasons, can be considered a full-fledged Semantic Web Portal since it aggregates different sources of information spanned across the Internet and presents them in a structured and user-friendly manner.

Structure of the Chapter

This chapter is organized as follows. The Section *Background* contains a description of the background technologies, metamodels and methodologies for Web engineering and Semantic Web applications (i.e., WebML, OWL, RDF, and so on). The Section *Requirements for Semantic Web engineering* presents a set of requirements that Web Engineering approaches for modeling Semantic Web applications must comply with, according to our analysis; The Section *Modeling Semantic Web application with WebML* proposes our extension of a metamodel for the design of Semantic Web portals (i.e., new primitives and metamodels within the WebML framework); in Section *Case Study: A Music Semantic Portal* we present a realistic Semantic Web portal scenario designed and implemented with the proposed methodology. The Section *Implementation Experience* discusses the architectural and implementation aspects of the proposed approach. Finally Section *Conclusion* and *Future Research Directions* propose a summary of the lesson learned from the research presented and possible research direction starting from the work reported in the chapter.

BACKGROUND

This section presents an overview of the background technologies and relevant work in the field of engineering Semantic Web applications. In particular we first introduce an overview of the most relevant languages adopted for defining and querying ontologies; then we present a review of relevant Web engineering methodologies that cover Semantic Web technologies; a subsequent paragraph is dedicated to introduce WebML, the Web application modelling language that we extend for supporting Semantic Web features (extensions are discussed in Section *Modeling Semantic Web application with WebML*).

Languages for the Semantic Web

Several ontology languages have been developed during the last few years, and they will surely be exploited in the context of the Semantic Web. Some of them are based on XML syntax, such as Ontology Exchange Language (XOL), SHOE (which was previously based on HTML), and Ontology Markup Language (OML), whereas Resource Description Framework (RDF) (W3C, 2004b) and RDF Schema (W3C, 2004c) are languages created by World Wide Web Consortium (W3C) working groups. Later, two additional languages have been built on top of RDF(S) - the union of RDF and RDF Schema - to improve its features: Ontology Inference Layer (OIL) and DAML+OIL. DAML+OIL was submitted to W3C as starting proposal for a new ontology language: OWL (W3C, 2004a). Recently, a new emerging initiative, the Web Service Modeling Ontology (WSMO), introduced a new ontology language called WSML (Fensel et al., 2006). A more detailed discussion can be found in Chapter *Ontology Languages for the Semantic Web: An Overview*. The ontologies adopted in our case study are a mix of RDF(S) and OWL, that are shortly presented in the next paragraphs.

Resource Description Framework and RDF Schema

RDF (W3C, 2004b), developed by the W3C for describing Web resources, allows the specification of the semantics of data based on XML in a standardized, interoperable manner. It also provides mechanisms to explicitly represent services, processes, and business models, while allowing recognition of non explicit information. The RDF data-model is based on *subject, predicate, object* triples, so called RDF statements, to formalize meta-data. RDF is domain independent in that no assumptions about a particular domain of discourse are made. It is up to the users to define their own ontologies for the user's domain in an ontology definition language such as RDF Schema (RDFS) (W3C, 2004c).

RDF statements are based on the concept of *resources*, which can be used in the different roles of the statement. A resource can be everything; a book, a person, a Web page, a CD, a track on a CD, and so on. Every resource is identified by a Uniform Resource Identifier (URI). In the case of a Web page, the URI can be the Unified Resource Locator (URL) of the page. The URI does not necessarily enable the access via the Web to the resource; it simply unambiguously identifies the resource.

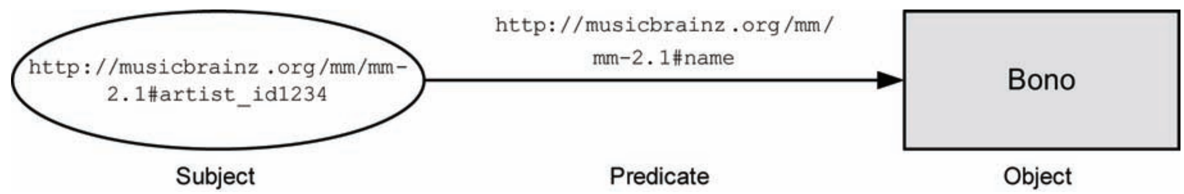
The *subject* of a statement is the resource we want to make a statement about. For example if we want to make a statement about a music artist, we need to identify it with a URI (e.g. http://musicbrainz.org/mm/mm-2.1#artist_id1234). The predicate defines the kind of information we want to express about the subject. For example if we want to make a statement about the name of the Artist we can use the URI http://musicbrainz.org/mm/mm-2.1#name that references the property defined in the ontology. The *object* defines the value of the predicate, for example in our case we want to state that the name of artist is "Bono". The object can be a literal, like in this example, or another resource represented by the object's URI.The statement presented can be written in triple notation as[a]:<http://musicbrainz.org/mm/mm-2.1#artist_id1234> <http://musicbrainz.org/mm/mm-2.1#name> "Bono".RDF supports also an XML syntax for writing and exchanging RDF graphs, called RDF/XML. The RDF/XML representation of the previous statement is:<rdf:RDF xmlns:mm="http://musicbrainz.org/mm/mm-2.1#" xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"><rdf:Description rdf:about="http://musicbrainz.org/mm/mm-2.1#artist_id1234"><mm:name>Bono</mm:name></rdf:Description></rdf:RDF>

A statement can be represented as a graph too, as depicted in Figure 1.

The RDF data model does not provide mechanisms for defining the relationships between properties (attributes) and resources - this is the role of RDFS (W3C, 2004c). RDFS offers primitives for defining knowledge models that are closer to frame-based approaches[b].

In particular RDFS introduces "meta"-classes that are used to define resource types: rdfs:Class

Figure 1. The graphical representation of a RDF statement.



to define RDF classes (concepts); rdfs:Literal to define literal values such as strings and integers; rdfs:Property to define properties. The full RDFS vocabulary and its description can be found in (W3C, 2004c). The following fragment defines the concept artist as previously introduced:<rdfs:Class rdf:about="http://musicbrainz.org/mm/mm-2.1#Artist"rdfs:label="Artist"><rdfs:subClassOfrdf:resource="http://www.w3.org/2000/01/rdf-schema#Resource"/></rdfs:Class><rdf:Propertyrdf:about="http://musicbrainz.org/mm/mm-2.1#name" rdfs:label="name"><rdfs:domain rdf:resource="http://musicbrainz.org/mm/mm-2.1#Artist"/><rdfs:range rdf:resource="http://www.w3.org/2000/01/rdf-schema#Literal"/></rdf:Property>

RDF and RDFS are not rich enough to completely describe an ontology as they still miss some important concepts within their Description Logic.

Ontology Web Language

OWL (W3C, 2004a) is designed for applications that need to process the content of information instead of just presenting information to humans. Furthermore OWL facilitates greater machine interpretability of Web content than that supported by XML, RDF, and RDF Schema (RDFS) by providing additional vocabulary along with a formal semantics.

OWL provides a number of additional modelling primitives that increase the expressiveness compared to RDFS and solve some shortcomings of RDFS:

- *Cardinality restrictions*. RDFS does not provide any means to restrict the number of distinct values a property may or must take.
- *Disjoint classes*. RDFS does not provide primitives to declare two classes to be disjoint.
- *Set combination of classes*. RDFS does not allow to define new classes by building the union, intersection, or complement of other classes.
- *Special characteristics of properties*. In RDFS is not possible to define that a property is transitive (e.g. greater than), unique (e.g. is mother of), or the inverse of another property.

The following OWL fragment represents a OWL properties and its inverse. The inverseOf element specifies that playedBy is the inverse of plays.<!-- Artist plays a Track--><owl:ObjectProperty rdf:ID="http://musicbrainz.org/mm/mm-2.1#plays"><rdfs:domain rdf:resource="http://musicbrainz.org/mm/mm-2.1#Artist"/><rdfs:range rdf:resource="http://musicbrainz.org/mm/mm-2.1#Track"/></owl:ObjectProperty><!-- Track played by an Artist --><owl:ObjectProperty rdf:ID="http://musicbrainz.org/mm/mm-2.1#playedBy"><rdfs:domain rdf:resource="http://musicbrainz.org/mm/mm-2.1#Track"/><rdfs:range rdf:resource="http://musicbrainz.org/mm/mm-2.1#Artist"/><owl:**inverseOf** rdf:resource="http://musicbrainz.org/mm/mm-

2.1#plays" /></owl:ObjectProperty>OWL has three increasingly-expressive sublanguages: OWL Lite, OWL DL, and OWL Full.

- *OWL Lite* supports those users primarily needing a classification hierarchy and simple constraint features.
- *OWL DL* includes all OWL language constructs with restrictions such as type separation (a class can not also be an individual or property; a property can not also be an individual or class). OWL DL is so named due to its correspondence with *description logics*, a field of research that has studied a particular decidable fragment of first order logic.
- *OWL Full* gives the maximum expressiveness and the syntactic freedom of RDF with no computational guarantees. For example, in OWL Full a class can be treated simultaneously as a collection of individuals and as an individual in its own right. It is unlikely that any reasoning software will be able to support every feature of OWL Full. For instance, general inference in OWL Full is clearly undecidable as OWL Full does not include restrictions on the use of transitive properties which are required in order to maintain decidability.

Query Languages for the Semantic Web

With the diffusion of RDF data sources, the problem of querying them in a easy way caused the flourishing of many different query languages for RDF based on different principles: some are inspired by SQL, like SPARQL (W3C, 2007) and RQL (Karvounarakis, 2004), others are based on different principles like graph patterns - e.g. TRIPLE (Sintek & Decker, 2002) - and reactive rules - e.g. Algae (Prud'hommeaux, 2004). In depth comparison of the most relevant RDF query languages can be found in (Haase et al., 2004; Furche et al., 2006); while a broader discussion of Web and Semantic Web query languages is presented in (Bailey et al., 2005). In the next paragraph we give some more details on SPARQL since it is probably the most adopted query language for RDF and it is the language adopted by our solution.

SPARQL

SPARQL (W3C, 2007) is a query language that has already reached candidate recommendation status at the W3C, and is on a good way to become the W3C recommendation for RDF querying. Querying RDF data with languages in the SPARQL family amounts to matching graph patterns that are given as sets of triples of subjects, predicates and objects. The triple syntax adopted by SPARQL is based on Turtle (Beckett, 2004). Solutions to SPARQL queries are given in the form of result sets: each result set contains a set of mappings from the variables occurring within the query to nodes of the queried data. For instance, the query that extracts the name and the nationality of all the Artists from the ontology previously presented can be written as:BASE <http://musicbrainz.org/mm/mm-2.1#>PREFIX mm: <http://musicbrainz.org/mm/mm-2.1#>PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>SELECT ?name ?nationalityWHERE{ ?id rdf:type mm:Artist .?id mm:name ?name .OPTIONAL{ ?id mm:nationality ?nationality .}}

The WHERE clause specifies the graph pattern to selected data to be mapped to the variables; variables are identified by either ? or $ prefix. The OPTIONAL clause specifies that a certain triple is optional: it is not compulsory that all the returned results contains the triples stated has optional. If the OPTIONAL clause is removed, the results will include only the triples that contain the whole graphical pattern requested. The FROM clause can be used to specifies the URL (or some other identifier) of the data to be queried.

SPARQL includes also other three types of query: the CONSTRUCT query clauses, that create new RDF graphs with data from the RDF graph queried; the DESCRIBE query that return RDF "descriptions" of the resources matching the query part (e.g., the query DESCRIBE mm:u2 returns a RDF graph representing the mm:u2 resource); and the ASK query that return true or false according to the fact that the specified pattern has a solution or not (e.g., the query ASK mm:u2 rdf:type mm:Artist returns true if the resource mm:u2 is an instance of the class mm:Artist).

Methodologies to Design Semantic Web Applications

While design methodologies for traditional Web applications offer rather mature and established solutions methodologies for developing Semantic Web applications are still in an early development phase. Realizing the benefits of the Semantic Web platform (e.g., interoperability, inference capabilities, increased reuse of the design artifacts, etc.) traditional design methodologies are now focusing on designing Semantic Web applications: e.g., OOHDM (Schwabe & Rossi 1998) evolved in SHDM (Lima & Schwabe, 2003). New methodologies like XWMF (Klapsing et al., 2001), OntoWebber (Jin et al., 2001) and Hera (Vdovjak et al., 2003) were specifically designed by considering the Semantic Web peculiarities. Among them, the most complete are Hera and SHDM that are shortly described in the next paragraph.

The Semantic Hypermedia Design Method

SHDM (Lima & Schwabe, 2003) is an ontology-based design methodology. It extends the expressive power of OOHDM (Schwabe & Rossi, 1998) by defining ontologies for each of the OOHDM models. These ontologies are specified in OWL, a more expressive language than RDFS. In the same way as OOHDM, SHDM identifies four different phases: conceptual design, navigation design, abstract interface design, and implementation.

The conceptual design builds the conceptual class schema for the application domain. This schema is described in UML extended with a few new characteristics like the ability to specialize relations. The UML diagram is mapped to an OWL model according to some heuristics rules.

The navigation design defines the navigational class schema and the navigational context schema. The main navigational primitives are navigational classes (nodes), navigational contexts, and access structures. In the same way as for the conceptual class schema, one can specialize navigational relations. The mappings between the conceptual schema and navigational class schema are defined using RQL. The navigation context allows the description of sets of navigational objects.

The abstract interface design defines the visual aspect of the deployed application by means of the abstract widget ontology and concrete widget ontology. The implementation phase produces a Semantic Web application based on the previous SHDM specifications.

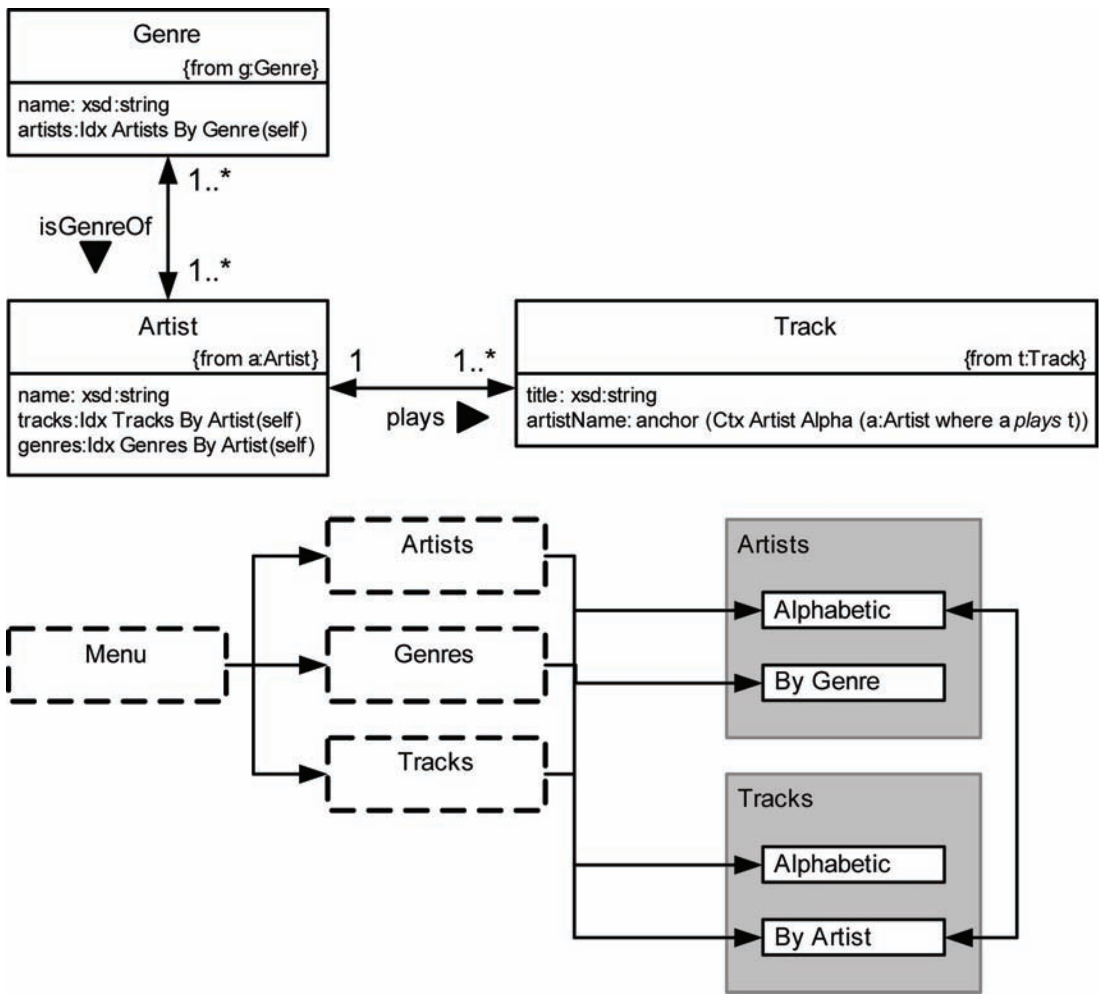
Figure 2 presents the Navigational Class Schema (top part) and the Navigational Context Schema (bottom part) of a simple Web application based on the musicbrainz and musicmoz ontology.

HERA

The Hera Methodology (Vdovjak et al., 2003) is a model driven methodology for designing and developing Web applications using Semantic Web technologies. It is developed from a database perspective; the conceptual modelling (similar to the ER modelling) and the querying of the different Hera models are important issues in the proposed methodology.

The Hera methodology has three main layers: *the conceptual model layer (CM), the application model layer (AM)*, and the *presentation model*

Figure 2. SHDM navigational design for a Web application based on the case study ontologies: Navigational Class Schema (top part) and Navigational Context Schema (bottom part).

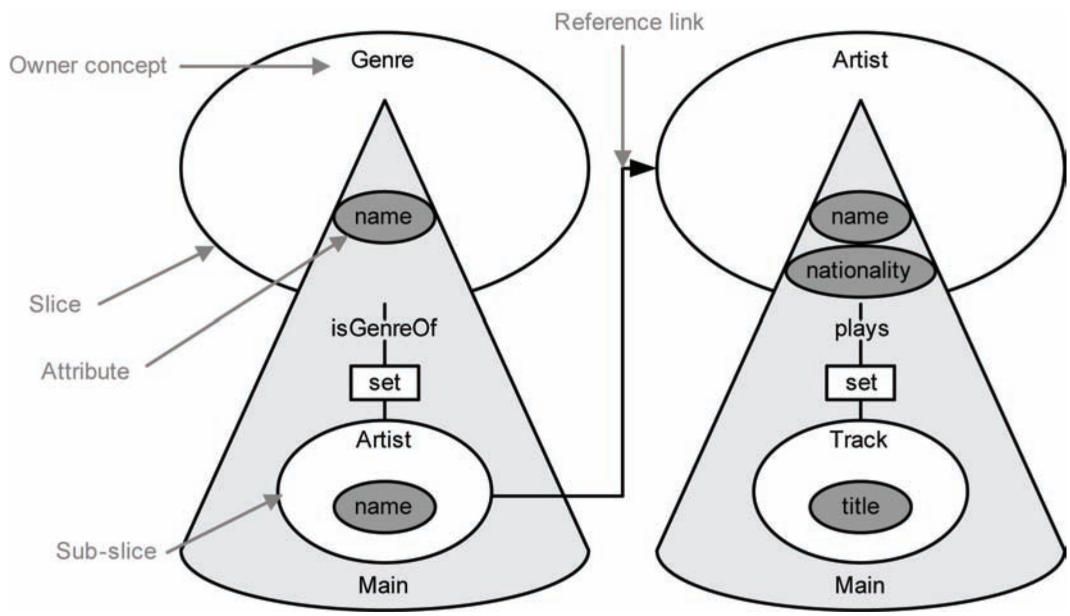


layer (PM). The first layer describes data content used for generation of hypermedia presentations and makes available data coming from different, possibly heterogeneous data sources; the integration of different data sources is possible thanks to a data integration model (a sub-layer that allows decoupling between the conceptual model and the data sources). The second layer describes the navigation structure and functionality; finally the PM layer describes spatial layout and rendering of hypermedia presentations. An orthogonal layer, called adaptation layer, captures adaptation issues in all the above layers.

By distinguishing these different layers, Hera differentiates at design level between the semantic aspects, the navigational aspects, and the interface aspects of a Semantic Web application.

The core components of the application model layer are called slices. They are associated with a concept from the CM model and may contain properties of the concept or other slices. Different not nested slices may be interconnected by slice relationships, that can be classified in aggregation relationships (e.g., index, tour, indexed guided tour, etc.) or reference relationships (i.e., links with an anchor specified). Slices represent views

Figure 3. An Hera application model based on the case study ontologies



over the conceptual model and are translated to RQL queries.

All the HERA models are, as matter of fact, ontologies, and hence a Web application model is a collection of instances of the different model ontologies. Therefore, it is possible to define a fragment of an application model as subclass of another fragment (this applies also the other two models).

Figure 3 presents a fragment of an application model based on the musicbrainz and musicmoz ontology: the first slice on the left represents a page that contains a genre and the set of artists linked to that genre; each artist is linked with a reference link to the artist slice that collects information about the artist an the set of tracks played by the artist.

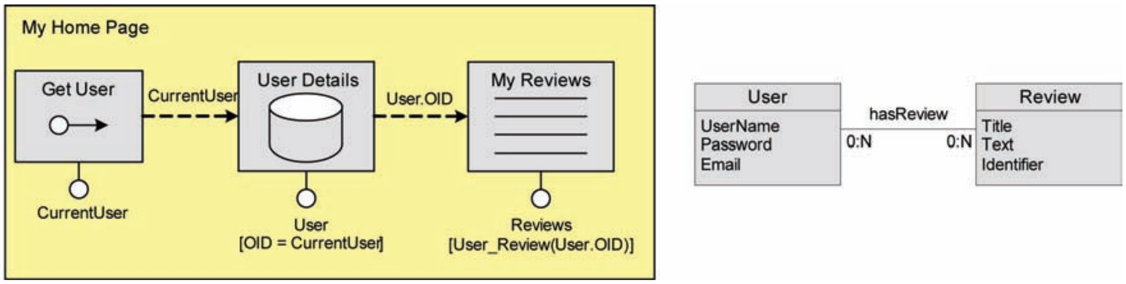
WEBML

Our approach to Semantic Portals specification is based on WebML (Ceri et al., 2002). In this paragraph we introduce the basic features of WebML; the extension we introduced to model Semantic Web applications is presented later in this chapter. WebML uses conceptual modeling techniques for describing web applications. The WebML design methodology comprises three main phases: data design, hypertext design, and implementation. It provides a visual notation and a XML serialization for the proposed models.

For specifying the data underlying the application, WebML exploits an extended version of the *Entity-Relationship* model, which consists of entities (classes of data elements), and relationships (semantic connections between entities).

The hypertext design defines the navigational structure of the application. WebML also allows designers to describe hypertexts, called *site views*, for publishing and managing content. A site view is a piece of hypertext, which can be browsed by a particular class of users. Multiple site views can be defined for the same application. Site views are then composed of *areas* and *pages*. Areas and pages can be nested in areas. Finally pages are the containers of elementary pieces of content, called *content units*, typically publishing data

Figure 4. An example Web page modeled in WebML (left) and its underlying data model (right)



retrieved from the database, whose schema is expressed through the data model. In particular, WebML primitives for content publishing denote alternative ways for displaying one or more entity instances: e.g., the *data unit* publishes a single instance of data, the *index unit* a list of data. Unit specification requires the definition of a source and a selector: the source is the name of the entity from which the unit's content is extracted; the selector is a condition, used for retrieving the actual objects of the source entity that contribute to the unit's content.

Between units/pages one can define hypertextual links as oriented connections. WebML distinguishes several types of links: *navigational*, *automatic*, and *transport* links. These links can carry information from the source to the destination. The information is stored in the link parameters. The navigational links require user intervention, while both automatic and transport links are traversed without user intervention: for automatic links once the source is presented also the associated destination is shown; the transport links do not define navigation and are solely used to transport information.

WebML also supports the specification of content management operations. They allow creating, deleting or modifying an instance of an entity (respectively through the *create*, *delete*, and *modify* units), or adding or dropping a relationship between two entity instances (respectively through the *connect* and *disconnect* units).

Figure 4 presents an example of WebML hypertext model and its underlying E-R model. It shows a single page, which allows the user to see his reviews about music albums. In the *My Home Page* a *Get* unit retrieves the identifier of the current user from the session parameter *CurrentUser* and provides it in input to the following *Data* unit, which publishes the user's personal profile data. The data to be published are restricted by means of a selector condition, specified below the unit. The user identifier is further propagated to the *Index* unit *My Reviews* by means of a transport link. The index unit shows the list of reviews related to the received user identifier.

WebML-based development is supported by the WebRatio CASE tool (WebModels s.r.l., 2007), which offers a visual environment for designing the WebML conceptual schemas, storing them in XML format, and automatically generates the running code (through XSLT model transformations), which is deployed as pure J2EE code.

REQUIREMENTS FOR SEMANTIC WEB ENGINEERING

While Web Engineering managed to bring software engineering practices to the Web development area, no discipline has addressed the peculiar needs of Semantic Web application design. A good methodology for the design of Semantic Web applications must provide additional facilities to the developer, specifically addressing the new needs. To understand them, we define the features of these applications, and then infer the characteristics of the methodologies and models that must be provided to the designer. To collect the requirements that a Semantic Web application should comply with, we analyzed some existing Semantic Web Portals (e.g., http://www.mindswap.org, http://Foafing-the-music.iua.upf.edu, and http://ontoworld.org) and we extracted the following set of needs:

- **Support of semantic languages:** Semantic Web applications should be aware of and support (i.e., be able to query and manage) different Semantic Languages and metamodels (RDFS, OWL, WSML, …).
- **Semantic application models:** Semantic Web applications should be designed and specified by means conceptual models that include and support semantic descriptions.
- **Flexible integration:** Semantic Web applications should embrace the philosophy of flexibility and heterogeneity integration of Semantic Web.
- **Classes and instances access and queries:** Both domain ontology classes and instances should be easily and seamlessly accessible by Semantic Web applications, through appropriate querying primitives, including data instance and structure queries.
- **Inference and verification:** Ontology-based web applications should exploit available inferring systems on ontological data, both for semantic queries and verification of data.
- **Semantic data sources:** A Semantic Web application relies on semantic data (e.g., ontologies) that offer a machine understandable data description that may be used to populate and generate Web pages and also to provide semantic annotations.
- **Importing and reuse of ontologies:** Semantic Web applications shall allow to: (1) import new (possibly distributed) data conforming to the Web application ontology; (2) to seamlessly integrate new ontologies, not fitting the default ontology; and (3) to reuse existing and shared ontologies.

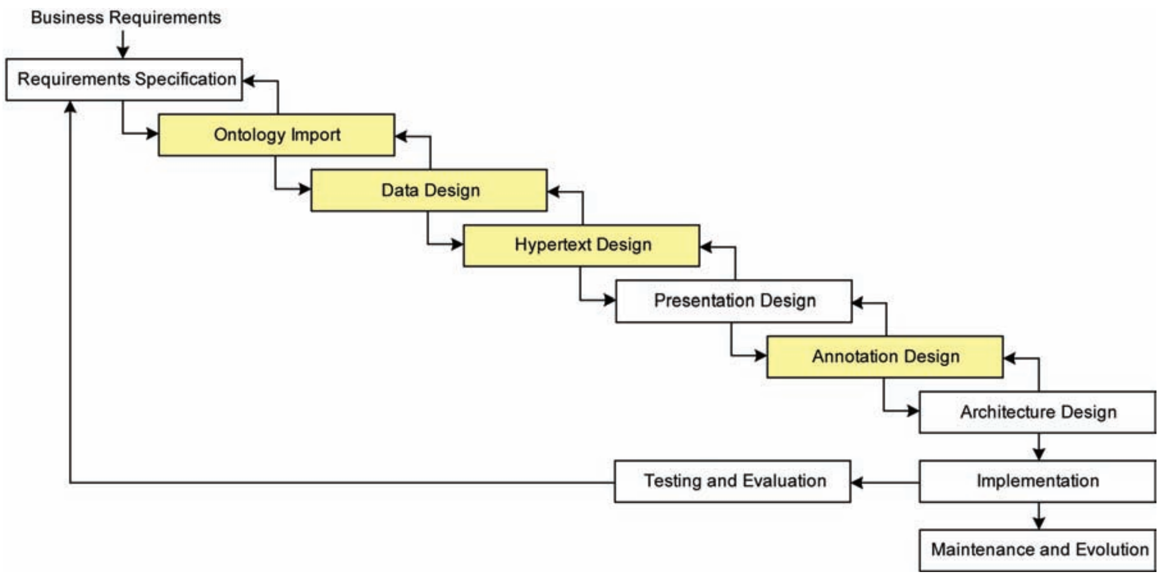
From the previous set of characteristics, we derived the following requirements for the conceptual models pursuing the design of Semantic Web applications:

- Semantic Web application models should be aware of and support semantic languages.
- The models themselves should be "semantic", i.e., grant self-annotation and explicit semantic extraction.
- The models should allow flexible integration of heterogeneous sources and applications.
- The models should allow transformations towards a query language able to capture all the aspects of ontologies, including inference, verification, query on instances, and query on classes.
- The models should easily allow: to specify semantic data sources as underlying level of the application; to exploit these sources for populating Web pages, and for (automatically) annotating such Web pages.
- The models shall be able to import and reference distributed data and ontologies, aiming at the reuse and sharing of the knowledge.

MODELING SEMANTIC WEB APPLICATIONS WITH WEBML

In this section we give an overview of extensions to the WebML methodology and models that we developed for complying with the requirements of Semantic Web applications (see previous section). WebML showed its flexibility and ease of extension in many other contexts (e.g., Web Services, Processes, Adaptive Web applications, Rich

Figure 5. The extended development process for Semantic Web applications, new and modified steps have yellow background



Internet applications): this allowed to consolidate and standardize the extension process. Basically, extending WebML for a new design domain (like Semantic Web portals) requires to introduce changes to the overall development process and to the related metamodels (and if required to introduce new metamodels in the development process). In particular, to deal with Semantic Web applications, we analyzed the current aspects of the WebML methodology and provided the proper extensions for each of them: the development process is enriched with steps that allow to describe the tasks related to the design of ontologies and semantics of the web applications/services; the data model is extended to support semantic data sources (i.e., ontologies); the hypertext model is enriched with new primitives that support ontology querying, with particular attention to advanced and inferring queries. Finally the presentation model is extended to allow for semantic annotations of the applications.

Extending the WebML Development Process

The injection of semantics within Web applications requires the extension of the methodology adopted in the development of "traditional" Web applications with additional tasks that formalize the new design steps. Figure 5 depicts the extended version of the development process for Web applications (yellow blocks represent the new tasks we introduced to fulfill Semantic Web application requirements). The original version was proposed in (Ceri et al., 2002) and is adopted with slight variations by most of the existing Web Engineering approaches. We want to stress that this development process is of general purpose and can be used for developing Semantic Web applications regardless of the use of any model-driven technique (actually it is valid also in case of traditional development techniques).

During *Requirements Specification*, a software analyst derives information about the application domain and functional requirements for the application from the business requirements and produces a detailed and formal specification for application designers. Already at this step some requirements related to semantic aspects can be highlighted and properly formalized. Based on the resulting specification, the designer can select existing domain ontologies to be imported (*Ontology Import*) and integrated in the Web application. Both ontology schemas and ontology instances maybe imported at this point. Never the less, for the Web application design, only ontology schemas are relevant. The imported ontologies can be possibly modified or merged to better suite the Web application purposes with specialized tools like Protégé (Noy et al., 2001). During the *Data Design* phase, the database structure and new ontologies can be created. Then, during the *Hypertext Design* the actual Web application structure is designed; in this phase, new primitives allows to specify how to query ontologies. Notice that the design of interactions with relational data remains unchanged with respect to the standard WebML design techniques. At this point the designer takes decisions about the *Presentation Design* of the Web application (e.g. design of graphical mock-ups and resources) and about the semantic annotations he wants to include in the rendered pages. The *Annotation Design* enriches the Hypertext Design and relies on the Presentation Design for deciding the actual position, formatting, and display style of annotations. *Architecture Design* mainly concerns the definition of hardware and software components as well as the design of the required network infrastructure. Once an overall application design has been specified, the *Implementation* phase can be carried out. It produces in output the software components (databases, ontologies, HTML templates, business logics, etc.) that build up the actual Web application, running on the selected architecture. During the following *Testing and Evaluation* phase, several tests (regarding e.g. functionality, usability, and performance) validate the application's conformance with respect to the initial business requirements, and could lead to novel derived requirements or modifications of the implementation. After testing, the application is released and undergoes ordinary maintenance and evolution activities. Notice that the waterfall representation may be adjusted for some design experiences, considering that in some cases some steps are not needed at all (e.g., if only imported ontologies are necessary, the data design step can be skipped). We did not depict all the variants for sake of clarity.

In the following paragraphs we discuss in more detail the changes introduced to the development process (yellow blocks in Figure 5).

Extending the WebML Data Model

Current existing model-driven methodologies for Semantic Web applications either evolved from existing ones by extending their data source coverage to ontologies, or have born with native support of semantic data sources.

Although ontology support is obviously necessary for Semantic Web applications design, we think that relational data sources can still provide great added value to Web applications. Relational databases are still a valuable option for modeling portion of domain data where features offered by ontologies are not needed (e.g., hierarchies, polymorphism, reasoning support, …) and where performances are a key issue (e.g., transactional data).

Therefore, allowing seamless interaction between ontologies and databases is a desideratum of current Semantic Web applications. Notice that we do not aim at extending the data model of WebML so as to model ontologies (see Noy et al. 2001), but at allowing Web applications to query imported semantic knowledge together with relational sources. By adopting a conceptual model, like WebML, interaction between ontology instances and database instances can be quite straightforward.

The designer is in charge of carefully deciding what is going to be part of an ontological data source and what is going to part of a relational data source. As data design (both in case of ontologies and databases) in general is an already consolidated discipline, we do not provide further details in this chapter. The only critical aspect is that the designer needs also to foresee if there is any need of references between the two data sources (e.g., the URI identifier of a Foaf user profile may be referenced in the relational schema to connect some relational attributes).

Extending the WebML Hypertext Model

WebML comes with a basic set of primitives for data access (e.g., *Index* unit, *Multidata* unit, the *Data* unit) that have a general purpose meaning (see Section "Background") and are perfectly fitting in the role of query and navigation primitives for both relational and ontology sources. Indeed, this is a general feature of conceptual models: if the used abstractions are generic enough, they do not need to be changed when their data source grounding is changed. They can be easily extended for supporting the additional expressive power and the different data model of the ontological sources.

For example, in WebML the *Index* unit is extended so that, besides extracting lists of relational instances, allows to produce lists of instances of a particular class within an ontology model. In previous sections we highlighted some requirements related to this kind of query: (1) the possibility to show only direct instances or also inferred instances; (2) the need for querying both instances and classes, thus mixing instances and (sub)classes in the results too. The same principles can be applied to *Multidata* unit and *Data* unit.

The *Hierarchical Index* unit, already defined in WebML, fits perfectly with the ontological data sources since it can be extended to browse and publish a portion of ontology in a hierarchical tree representation: for instance, given a class, it allows to publish the hierarchical tree underlying it, comprising subclasses and instances.

As stressed above, these basic WebML primitives remain valid, nevertheless they require some small extensions to support challenges posed by ontological data sources. Ontologies allow for queries with a wider expressive power and require some different modeling rules for the information within respect to relational data. This reflects into changes in the notations that the primitives must use for defining the conditions and the selection of the data.

Some of the challenges posed by ontologies are:

- There is no distinction between relationships and attributes within the set of properties of a class. E-R style relationships might be considered as ontological properties having an URI as value, and attributes to ontological properties having a literal as value;
- Several Semantic Web framework (e.g., OWL, RDF) assume that any instance of a class may have an arbitrary number (zero or more) of values for a particular property;
- Properties specification may include cardinality constraints and classes as range (and of course domain). In this case, it is possible to publish as values also structured objects and not only atomic attributes.

The revised units allow to model in a visual and simple way queries over ontologies. The data integration between relational data sources and different ontologies can be tackled directly in the Hypertext Model, by exploiting the data flow mechanism provided by WebML. One of the main advantages of WebML is the ability to specify business logic of applications by interconnecting smaller business logic components (units) in chains and passing parameters between them. This allows to define complex business logics composed by units that may query different ontologies or relational data sources and then can exchange information along the chain of transport links in a very easy way. Thus, parameters on the links become the actual contact point between traditional and semantic data and provide the mechanism for orthogonalizing data issues and hypertext issues.

Advanced Data Access Primitives

Many possible queries, using semantic data sources and semantic query languages, cannot be expressed using the basic data access primitives presented in the previous section. By carefully analyzing the semantic query languages presented at the beginning of the chapter, we introduce a new set of operational primitives that cover advanced queries over ontological data available in these languages. In particular these new units are largely influenced by two languages presented in the background section, namely, SPARQL (W3C, 2007) and RDF Schema syntax (W3C, 2004c). SPARQL was also selected among the various semantic query languages as the one adopted in the implementation of the runtime components (see Section *Implementation Experience*) because of its large software support and because it is probably going to become a W3C Recommendation.

The core set of new units aims to fill the gap between the basic WebML querying primitives and the increased expressive power of semantic languages. The basic primitives can not be combined to design any query that heavily exploits reasoning and mixing between schemas and instances. Thus, the basic WebML primitives miss two of the main assets of semantic languages. For example, they do not allow to infer all the classes an instance belongs to; they do not allow to infer the classes a particular property belongs to (in ontological models, a property can be associated to more than one class, since it is modeled independently from the class itself). The new units (i.e., *SubClassOf*, *InstanceOf*, *HasProperty*, *HasPropertyValue*, *SubPropertyOf*), described in Figure 6, aim at providing explicit support to advanced ontological queries and allow to extract classes, instances, properties, values; to check existence of specific concepts; and to verify whether a relationship holds between two objects. These units have a polymorphic behaviour: their business logic and the results returned change according to the configuration of their input parameters. The complete summary of the behaviour of these units is presented in Table 1.

Some other capabilities are needed within Semantic Web applications. For instance, we may need to import at runtime ontologies instances compliant with ontological schemas defined (or imported) at design time; to extract semantic descriptions of ontology portions; or to merge and compose ontologies. To this purpose, we introduce three new units, visually represented in Figure 7. The *Set Composition* operation unit is able to perform classic set operations (i.e., union, intersection, difference) over two input sets of URIs, considering the hierarchy of the URIs involved. E.g. suppose we have two set of classes: A = {ProgressiveRock, Jazz, Metal}B = {Rock, JazzFusion}.In this case, the set operation will give the following results:*A ∩ B = {ProgressiveRock, Metal, JazzFusion}A ∪ B = {Rock, Jazz}*

since Rock is superclass of ProgressiveRock and Metal, and Jazz is superclass of JazzFusion.

The *Import Ontology* unit allows to import at run time ontological data sources consistent with one or more of the ontology models imported at design time. This unit validates imported data against existing schemas and according to the designer choice, allows to store only the url of the newly imported ontology (i.e., it will be remotely queried every time, so modification on the remote source will be propagated to the application) or to import the ontology in the local OWL/RDF repository (i.e., it will be accessed locally, but modifications to the original data will not be propagated to the application). Notice however that in our methodology the navigational model of the Web application cannot be changed dynamically at runtime, thus if the imported ontology contains a new class unrelated with already existing classes queried in the hypertext, these new class will not be reachable in the navigation of the hypertext.

The *Describe* unit returns the RDF description of an URI, thus enabling data exporting and semantic annotation of pages.

The different advanced querying units are designed such that they can be combined in chains to compose complex business logic pattern that that allows to retrieve artists or albums that are correlated to artist searched by the user. The value submitted in the form is passed to an index unit that, by means of a filter, extracts all the Artists whose name contains in the string submitted by the user. The URI of the Artist picked from the index is passed to the *HasPropertyValue* unit. This unit extracts a set of URIs (instances of the class Album or Artist) that have the passed URI as

Figure 6. The new WebML units for advanced queries on ontologies

Unit name and Symbol	Input	Output	Description
SubclassOf [ClassName1=?] [ClassName2=?]	c_1, c_2 c_1, ? ?, c_2	true if c_1 is subclass of c_2 the list of superclasses of c_1 the list of subclasses of c_2	Given two classes, it returns true if the first is subclass of the second. Given a class, it returns the list of its subclasses or superclasses.
InstanceOf [ClassName=?] [Instance=?]	i, c i, ? ?, c	true if i is instance of c the list of classes for i the list of instances of the class c	Given a class and an instance, it returns true if the object is instance of the class. Given a class, it returns the list of its instances. Given an instance, it returns the list of the classes it belongs to.
HasProperty [ClassName=?] [Property=?]	c, p c, ? ?, p	true if the class c has the property p the list of properties of the class c the list of classes having p	Given a class and a property, it returns true if the class includes the property. Given a class, it returns the list of its properties. Given a property, it returns the list of the classes it belongs to.
Has PropertyValue [Property=?] [Value=?]	p, v p, ? ?, v	the list of URIs where the property p has value v the list of possible values for the property p the list of properties with value v	Given a property and a value, it returns the list of resource that has that property with that value. Given a property, it returns the list of all the possible values of the property. Given a value, it returns the list of properties with that value.
Subproperty [Property1=?] [Property2=?]	p_1, p_2 p_1, ? ?, p_2	true if p_1 is subproperty of p_2 the list of superproperties of p_1 the list of subproperties of p_2	Given two properties, it returns true if the first is subproperty of the second. Given a property, it returns the list of its subproperties or superproperties.

Table 1. Design time and runtime descriptors for two semantic units

	Design Time Descriptor	Runtime descriptor
Semantic Index unit	<SWINDEXUNIT class="mf:Track" id="swinu1" name="Tracks" ontology="onto1"> <DisplayedProperties property="mf:title"/> <DisplayedProperties property="mf:descriptor"/> <SortProperties order="ascending" property="mf:title"/> <Filter boolean="or"> <FilterCondition id="fselector1" property="mf:playedBy" predicate="eq" name="Artist"/> </Filter> </SWINDEXUNIT>	<descriptor service="org.webml.onto.SWIndexUnitService"> <onto>onto1</onto> ... <input-params> <input-param type="mm:Artist" name="swdau2.rdf:ID" /> </input-params> ... <query type="SELECT"> SELECT DISTINCT ?instance ?p1 ?p2 WHERE {?instance rdf:type mm:Track . ?instance mm:title ?p1 . ?instance mm:descriptor ?p2 . ?instance mm:playedBy ?fs1 . FILTER (?fs1 = $swdau2.rdf:ID$)} ORDER BY DESC(?p1) </query> </descriptor>
Subclas-sOf unit	<SUBCLASSOFUNIT id="iof1" name="SubClassOf" ontology="onto1"> </SUBCLASSOFUNIT>	<descriptor service="org.webml.onto.SubClassOfUnitService"> <onto>onto2</onto> ... <input-params> <input-param type="mz:Genre" name="swinu3.rdf:ID" /> </input-params> <query type="SELECT"> SELECT ?id WHERE {?id rdfs:subClassOf $swinu3.rdf:ID$} </query> </descriptor>

is then passed to the *InstanceOf* unit that checks if they are instances of the class Artist. In this case, the URIs are passed over through the OK link to an index unit showing a list of Artist, otherwise the URIs are passed on the KO link to publish a list of Album (not shown in the figure).

Extending the Presentation Model to Support Semantic Annotations

Each WebML semantic unit has been designed as able to automatically extract a RDF description of its contents. The designer has to specify in the HTML templates how he wants to use the RDF annotations. This RDF fragments can be used to

Figure 7. Symbols of the new WebML semantics management units

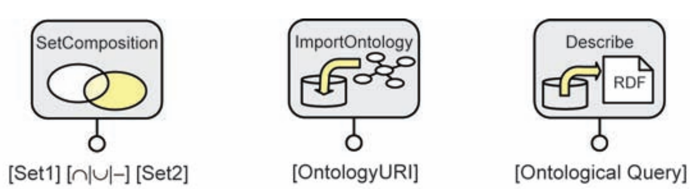


Figure 8. A portion of a Semantic Web application described by the new WebML units

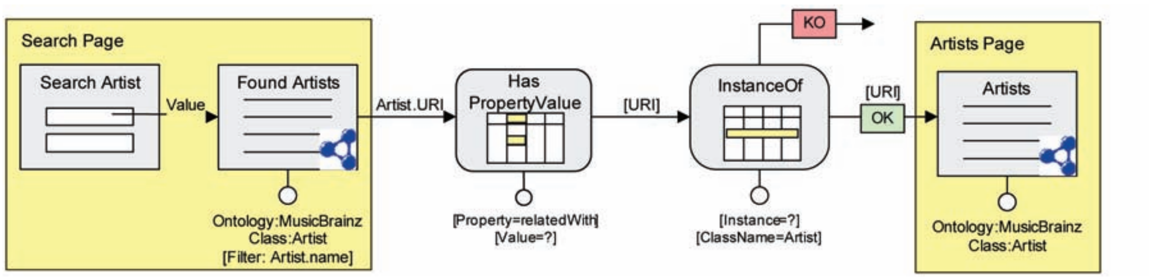


annotate a single portion of the page (the one where the unit is rendered) or they can be aggregated and published together in a single predefined location, as a global semantic annotation of the whole page itself. Annotations can be made visible in the page for user reference or kept hidden in the HTML code if they are meant to be used only by machine readers. The WebML presentation model (that allows to place objects in a page grid, according to appropriate styles) can be exploited for defining how and where semantic annotations are rendered within the generated pages. If advanced annotation is needed, the solution is the *Describe* unit, which allows to query the ontologies to extract complex RDF fragments to be used as annotations. In this way, it is possible to extract semantic fragments also of instances or classes not published in any content unit of the displayed page. Different templates may be applied to different portions of the application according to the requirements of the developed Web application.

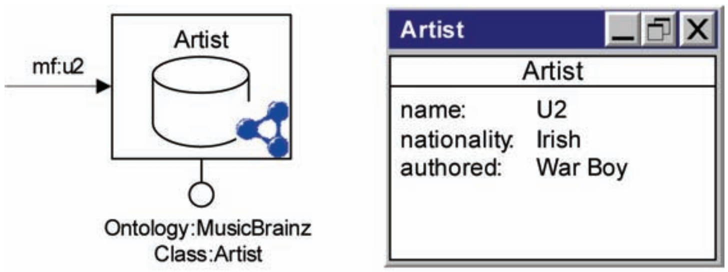
For example, the designer may decide to adopt a template that generates RDFa (Adida & Birbeck, 2007) annotations. RDFa is a syntax that expresses the structure underlying the published data using a set of elements and attributes that embed RDF in HTML. An important goal of RDFa is to achieve this RDF embedding without repeating existing HTML content when that content is the structured data. Within our framework RDFa is particularly easy to adopt since published data reflects an ontology schema; each displayed property value can be simply published with the proper reference to its property URI (setting the property attribute in the surrounding HTML tag), and reference resource (setting the about attribute in the surrounding HTML tag). Once the designer has defined the generic template, correct annotations are extracted in an automated way at runtime according to the underlying ontological model. Figure 9 presents an example of data unit with the relative generated RDFa annotation.

CASE STUDY: A MUSIC SEMANTIC PORTAL

In this section we show a simplified example of a Semantic Web portal modelled with WebML leveraging on the extensions we introduced in the previous section. For the design of the application we adopt the ontologies cited in the Introduction, namely the MusicBrainz ontology, the ontologization of the MusicMoz hierarchy; the RDF Site Summary for music news; and the Friend Of A Friend (Foaf) ontology. The main ontology adopted in the case study application is the MusicBrainz ontology; Figure 10 visually represents a fragment of it. The application includes also a small relational schema that contains registration information for the users, described by the User entity with its login data and the URI of its corresponding Foaf profile, if he has imported one in the Web application.

Figure 11 reports a fragment of the WebML model for the proposed application: content

Figure 9. An example of data unit with the relative generated RDFa annotation (highlighted in black).



```

  </TR>
  <TR>
    <TD>
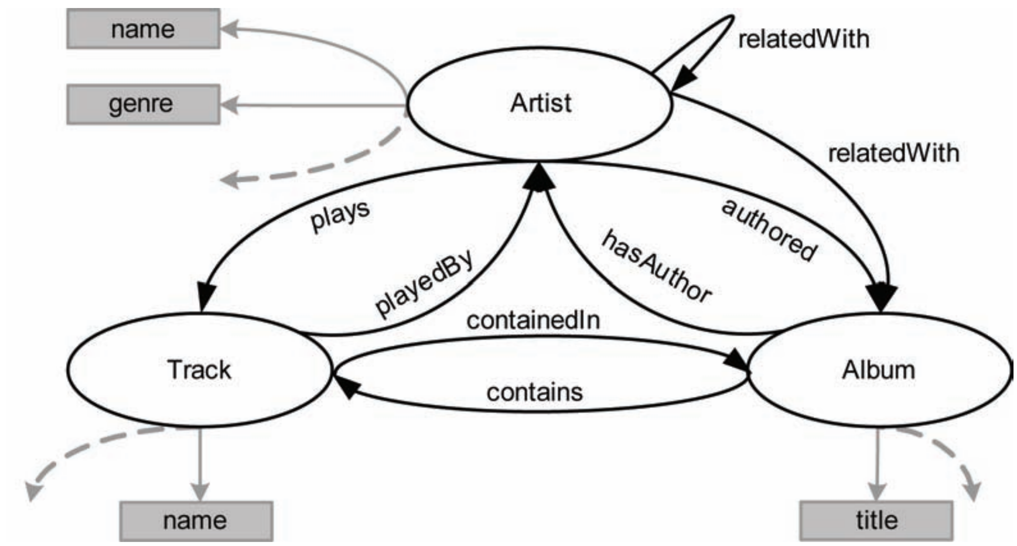
      <SPAN property="mf:authored" content="mf:War"
       about="mf:u2">War</SPAN>
      <SPAN property="mf:authored" content="mf:Boy"
       about="mf:u2">Boy</SPAN>
    </TD>
  </TR>
</TABLE>
```

units with the RDF symbol use ontological data sources (e.g., *Artists* index unit), while the other units publish data from the a relational database (e.g., *User Data* data unit). The user starts his navigation from the *User Home Page*, where the *Foaf Profile* data unit is published; the user also import a profile if it is not available yet. This part of the application actually shows how integration between ontological data sources and relational data can be achieved using parameters transported over links: when the user imports the ontology that represents his Foaf profile, he actually stores the URI of the profile in the *User* relational entity; this URI is later used to publish his Foaf profile from the ontology repository according to the database schema.

The user can navigate from *Foaf Profile* data unit to the *Suggestion* page that presents an index of Artist corresponding to his preferences. From here (and from any other page presenting a visual query over the Artist class) the user can browse the *Artist details* page, where detailed information about the selected Artist and his Album are presented. The user can ask for the exporting of the RDF description of the Artist he is currently browsing. From the *Albums* index unit is possible to reach the *Album Details* page that reports information on the navigated instance of Album and its Track instances. Then accessing the landmark page *Search by genre* (a landmark page is a page accessible from any point in the hypertext also without an explicit link), the user can navigate a hierarchical representation of the class Genre, and then accesses all the Artist instances that are related to the selected genre. The *SubClassOf* unit extracts indirect sub-genres of the chosen one, thus

Figure 10. A fragment of the MusicBrainz ontology representing Artist, Album, and Track, with the respective relationships



allowing to display associated artists. Finally the *News* page reports an index of RSS Item and, by selecting an item from the list, the user can display the Artist associated with it (thanks to the filter that allows to retrieve Artist instances whose name or alias is included in the title or in the description property of the item). New sources of RSS Item may be imported adopting the *Import Ontology* unit, such as in the case of the Foaf profile.

IMPLEMENTATION EXPERIENCE

In this section we discuss the architecture design we adopted to implement the presented extensions to the WebML metamodel. These design choices are discussed according to the reference implementation of WebML, the Webratio toolsuite (WebModels s.r.l., 2007). As API to integrate ontologies both in the design environment and in the runtime framework we adopted the Jena framework (HP, 2007), while the reasoning support is obtained by means of the Jena integrated reasoner, or by means of the integration of Pellet (Sirin et al., 2007) with the Jena framework (the choice is made by the designer from the CASE tool). The runtime environment offered by Webratio has been extended exploiting the plug-in mechanism of the toolsuite:

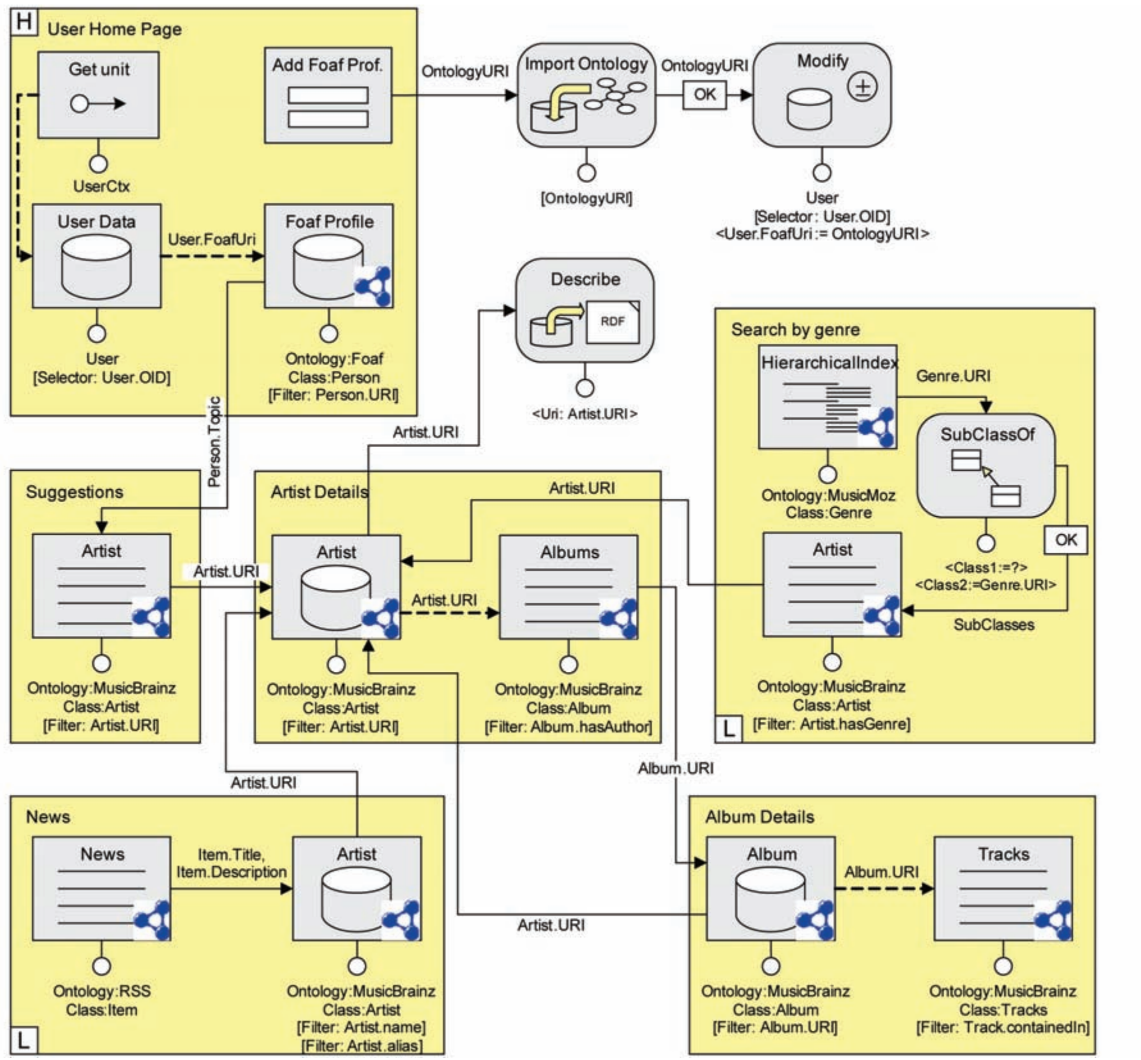
- We devised a general purpose ontology data access layer to be exploited by every unit;
- Then, we developed a runtime Java component and an XML descriptor for each unit.

Some extensions were needed on the design time interface too, in order to provide the proper management of ontological sources and units. Figure 12 reports a screenshot of the extended design environment showing the use case Semantic Web application presented in the previous section.

Implementing the Ontological Units

In the WebRatio framework, each unit is implemented by means of a generic class representing the runtime component that is executed for every instance of that kind of unit. Then, for each new

Figure 11. A portion of a WebML diagram for a Semantic Music Portal

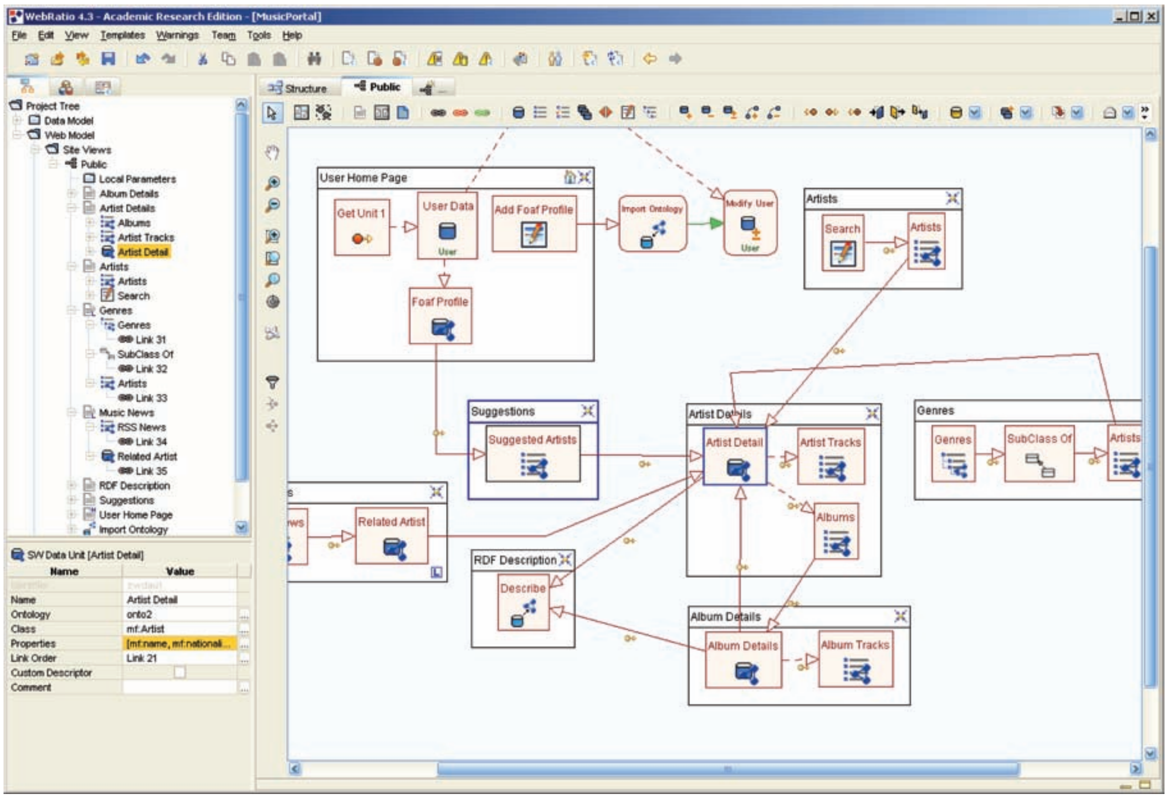


unit (including the revisited traditional units that access ontologies) we developed an XML descriptor specifying its parameters, its properties, the binding to the implementation classes, and so on. To better clarify the structure of the descriptor, we show two examples of an ontological unit descriptors (see left column of Table 1). By means of an associated XSLT transformation, design time descriptors are translated to runtime descriptors that include automatically generated template of SPARQL queries (right column of Table 1). Units are implemented by Java components that behave according to the logics specified in the runtime descriptors, defined for each instance of the unit.

Ontological Data Source Layer

We defined a new data access layer to allow the interaction with ontologies, comprising a set of general purpose Java classes to be reused by all the new units for querying the ontology repositories. These classes provide facilities to import ontologies and to select OWL/RDF classes, properties,

Figure 12. The Semantic Web Portal for the Music domain modelled with the WebRatio CASE tool



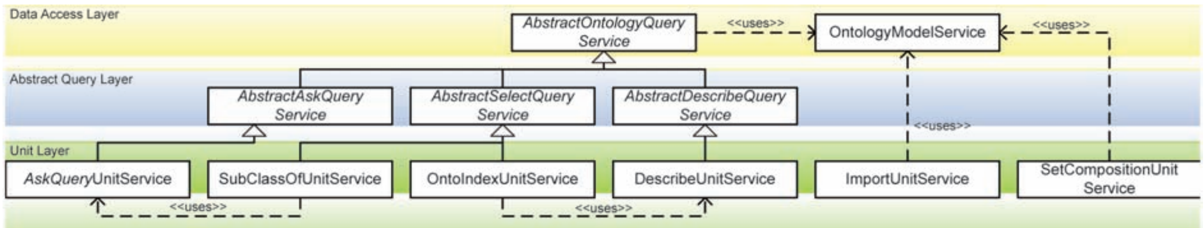
and instances (possibly filtered by one or more conditions). The main aspects of the class structure are represented in Figure 13. The *OntologyModelService* enables connections to local and remote ontologies specified at design time or imported at runtime by means of the Import Ontological Source unit. Three abstract classes offer the query services corresponding to the query methods offered by SPARQL on the ontology contents: the *AbstractSelectQueryService* class perform selection over data (SPARQL SELECT query); the *AbstractDescribeQueryService* retrieves the RDF describing a given URI (DESCRIBE query), the *AbstractAskQueryService* verifies simple predicates (ASK query). The AbstractAskQueryService is extended by the *AskQueryService* that is used by some of the advanced querying units to verify predicates (e.g., to check whether a class is subclass of another). In general, ontological unit services use or implement these general purpose services.

CONCLUSION

In this chapter we presented our research on the design of Semantic Web applications; we introduced briefly all the used background technologies and languages that are at the core of our proposal or that are adopted by other well-known frameworks. To ease the comparison of our work with other solutions, we described in detail Hera and SHDM, the most complete existing solutions.

The core of this chapter is the presentation of our extension to the WebML methodology and models for supporting the design and the specification of Semantic Web applications. The described solution provides a full coverage of the

Figure 13. UML class diagram of the class hierarchy of the new implemented units



development process: it allows the designer to specify basic and advanced queries on ontological data sources, to import existing sources, and to annotate Web pages with semantic descriptions of the contents and of the models. Our approach provides substantial added value with respect to the existing frameworks for Semantic Web application design, although some of them are more advanced on some aspects (e.g., seamless integration of different ontologies).

Table 2 reports a summary that compares the features of the previously cited models for Semantic Web Portals and the WebML extensions presented in this chapter. All the methodologies, except for XWMF, have a complete development methodology that covers all the needed aspects to create a Semantic Web application. They also offer a wide support for ontology languages: basically all the models support both RDF and OWL (except for XWMF). However, our extension is the only one that leverages on Semantic Web query languages to offer advanced query primitives that allow both query on schema and instances, together with simple reasoning patterns over data. Other models (e.g., Hera) offer query on data schema and instances. Hera and OntoWebber offer direct support to data integration by means of an integration model that can be used to query different data schemas using the same query. WebML offers the chance to integrate relational, XML and ontology data sources, while other methodologies seem to support explicitly only ontologies (of course, this issue can be solved by adopting extraction techniques to import other data sources within ontologies).

SHDM does not allow to import ontologies but only to create them from UML diagrams. Then, it offers a tricky way to link these ontologies to the external ones. Only a specific WSDM extension (Casteleyn et al., 2006) provides an approach to annotate pages so as to make them machine readable. Most of the new methodologies offer runtime frameworks that include or allow integration of reasoners, while some of them do not clarify if the reasoning is supported also at design time.

An important factor to assure the success of a design methodology is the existence of CASE tool support, since a powerful methodology that is not accompanied by adequate tools will make the designer tasks very difficult to fulfil. While most of the traditional design methodologies have powerful CASE tools, no established tool support is provided for Semantic Web design, although all the cited methodologies offer some basic tools. We support our proposal with a prototype implementation within the CASE tool WebRatio.

FUTURE RESEARCH DIRECTIONS

Future research will span on several directions: one of the main aspect we want to address is to generalize the way for extending the querying expressive power of the WebML units. Indeed, the provided extensions address some specific additional query power, but if further query ex-

Table 3. Comparison of methodologies for modeling Semantic Web portals

Requirement	XWMF	OntoWebber	SHDM	Hera	WebML+Sem.
Methodology	Partial	Yes	Yes	Yes	Yes
Semantic Model Description	Yes	Yes	Yes	Yes	Partial
Advanced query support	No	Partial	Partial	Partial	Yes
Flexible integration	No	Partial	Yes	Yes	Partial
Heterogeneous data sources	No	No	Partial	Partial	Yes
Distributed data sources	No	No	No	Yes	Yes
Reuse of ontologies	Yes	Yes	Partial	Yes	Yes
(Automatic) Annotation	No	No	No	No	Yes
Reasoning Support	No	No	Yes	Yes	Yes

pressive power is needed, researchers will need to devise new appropriate units. With a general representation framework, we plan to avoid this burden and to provide a quicker and more compact way for obtaining the results.

Another interesting aspect that was highlighted by this extension experience is related to the traditional way in which WebML provides querying facilities: standard WebML units (index unit, multi-data unit, data unit, and so on) provide both query service and publishing features in one single component (the *unit* specified within the page). Our extensions instead provide components that offer only the query services, without dealing with publishing, which is left to traditional WebML units. This separation of concerns could probably be applied to traditional querying too, so that the two aspects are always kept separate. This would mean a deep rethinking of the WebML hypertext models. We plan to consider this hint and to study possible solutions to the problem in the immediate future.

Besides pure research topics, we plan to extend and refine our implementation. Future implementation work includes:

- Providing a content integration layer to allow for seamless integration of different ontologies;
- Extensive testing of the new framework, including the application of the approach to real industrial scenarios;
- Integration of existing Eclipse based solutions for ontology editing with in the CASE tool.

ENDNOTES

1. The serialization reported is the TURTLE (Beckett 2004) RDF serialization format.
2. Frame based languages are metalanguages that apply the frame concept to the structuring of language properties. They are rather focused on the recognition and description of objects and classes, and relations and interactions are considered as "secondary". They are widely adopted for ontology modeling since inference based on them it's easier than using other paradigms.

APPENDIX: QUESTIONS FOR DISCUSSION

Beginner

Q1: Are model-driven techniques influenced by technology changes?

A: Model-driven techniques aim at abstracting the modeling layer of applications from the actual implementation layer. I.e., model-driven approaches should capture abstract characteristics of the application field so that their model is resilient to technology changes and to the different implementation platforms that can be chosen. For example, the WebML methodology proposed in this chapter showed how abstraction introduced to handle relational data are still valid for semantic data sources, proving that the abstraction level of the adopted primitives doesn't depend on the underlying implementation and the underlying technologies (SQL or SPARQL). The same discussion applies to SHDM that evolved from OOHDM.

Q2: Why the import and reuse of ontologies is a key requirement for Semantic Web applications?

A: Reuse is one of the key goals of Software Engineering and is usually widely applied to software components and libraries. This aspect is even more emphasized at the level of semantic content specification and usage. Thanks to the introduction of Semantic Web languages, like OWL, also data model can be widely reused and shared. Indeed, one of the key factors for the success of the Semantic Web initiative is the spread of a set of domain ontologies with a wide consensus on their definition. This will enable different applications to be transparently integrated thanks to the fact that they are sharing the same data model.

Intermediate

Q3: Why the adoption of a standard query language is important in the definition of metamodels for Semantic Web applications?

A: The use of a standard query language contributes to abstract furthermore the modeling layer from the actual implementation. Indeed, if the implementation of the conceptual primitives relies on a specific API, this implies the change of the whole querying mechanism (comprising the generation of queries) if a slightly different implementation is chosen. On the other hand, the use of a query language (like SPARQL) enables to change the adopted implementation at the lower level of the adopted query engine. This is particularly evident with relational database technologies, where the SQL language (and possibly some standardized APIs like JDBC/ODBC) allows for (theoretical) total independence from the actual database engine adopted. Semantic Web technologies are still evolving very quickly, therefore a similar decoupling is still missing, but probably the wide adoption of the SPARQL language will provide a similar benefit.

Advance

Q4: The WebML extension for Semantic Web achieves different source integration thanks to parameter passing on the links between WebML components. Is there any other valuable option that still maintains valid the primitives proposed and offer the opportunities to integrated different data sources?

A: This issue can be easily solved by adopting one of the currently available semantic bridges that allows to use a single domain ontology to which heterogeneous data sources can be mapped (e.g., relational databases, ontologies, web services, xml documents). The mapped data sources can then be accessed through queries (e.g. SPARQL queries) to the domain ontology. The adoption of such a technology will affect only the implementation layer, maintaining valid the design primitives proposed and the generated SPARQL queries from the ontology model. The main difference stands on the level where integration occurs: instead of integrating the sources at the application modelling level, sources are integrated at the data design level.

Practical Exercises

Exercise 1. Define a navigation model for allowing users to navigate the popular Wine ontology using the WebML notation (http://www.w3.org/TR/owl-guide/wine.rdf)

Solution:

The simplest solution is to provide access to the wines directly through the wine categorization provided in the ontology or through flavors. A hierarchical index can be used for browsing the wine categories and selecting a wine. The Wine Details page shows the information of the selected wine.

Two simple index units can be used to display the flavors and hence to show the wines of the selected flavour. Once a wine is chosen, the user is sent to the Wine Details page again.

Exercise 2. Define a navigation model using the SHDM model-driven methodology for the Wine ontology that displays a result similar to the navigation model created in WebML.

Solution:

The content model shows the fragment of ontology that has been used. The navigation model represents a similar navigation to the one shown for WebML

Exercise 3. Model a WebML diagram that allows to select a Grape instance and then retrieves all the classes of Wine that use the selected Grape.

Solution:

The solution consists of an index unit that allows to select instances of class WineGrape, and of a chain of semantic query units that select all the objects made from the chosen grape (the HasPropertyValue unit) and then, among the returned objects, extract all the classes of the elements of the returned objects (InstanceOf unit). Finally, the list of classes is shown in an index. Notice that the parameter *[URI]* represents the set of URIs resulting from the respective queries.

Chapter 2.17
Enabling Distributed Cognitive Collaborations on the Semantic Web

Amna Basharat
National University of Computer and Emerging Sciences, Pakistan

Gabriella Spinelli
Brunel University, UK

ABSTRACT

To date research on improving the state of multi-agent collaboration has only focused on the provision of grounding tools, technologies, protocols, standards and infrastructures that drive the Semantic Web and agent architectures. The basic cognitive and interactional requirements of agents have been neglected leading to the current state-of-the-art development of the Semantic Web whereby its full potential is constrained by the rigid state of multi-agent collaboration. This chapter illustrates and discusses an alternative approach to the development of the agent mediated Semantic Web. The fundamental premise of our approach is that enhancing agents cognitive and interactional abilities is the key to make the digital world of agents more flexible and adaptive in its role to facilitate distributed collaboration. The novelty of this research is that it adapts cognitive models from HCI to develop a heuristic framework called Cognitive Modelling of Multi-Agent Action (COMMAA) for modeling agents' actions in an attempt to provide an architecture that improves the flexibility of Multi-agent interaction by promoting cognitive awareness. The results of the evaluation show an improved flexibility, interoperability and reusability of agents' collective behaviours and goals.

INTRODUCTION

Agents may be autonomous and intelligent entities which typically operate in distributed collaborative environments called Multi-Agent Systems (MAS) which allows multiple heterogenous agents to collaborate by engaging in flexible, high-level interactions (Wooldridge, 2002; Jennings 2000). Presently, the usability of agent-based applications in a Semantic Web environment is limited due to lack of flexibility in agent's collaboration with multiple agents including humans. This imposes constraints on the interoperability and reusability of agents' behaviour that operate in MAS environment. In addition, the inflexibility of the agents' behaviour does not provide direct mapping to the end user since the end user cannot predict how the agent will behave, thus generating cognitive overload on humans. To date, research on improving the state of multi-agent collaboration has only focused on the provision of grounding tools, technologies, protocols, standards and infrastructures that drive the Semantic Web and agent architectures. Neglect of basic cognitive and interactional requirements are discovered to be the basic reasons for the rigid state of multi-agent collaboration constraining its full potential.

This research presented in this chapter adapts a distributed cognitive view of the agent mediated Semantic Web and argues that enhancing cognition is the key to make the digital world of agents more flexible and adaptive in its role to facilitate distributed collaboration. To this end, work on imparting cognition to improve interaction between multiple agents has been limited. The novelty of this research is that it adapts cognitive models from HCI to develop a heuristic modelling framework for COgnitive Modelling of Multi-Agent Actions (COMMAA) in an attempt to provide an architecture that improves the flexibility of Multi-agent interaction by promoting cognitive awareness. The highlight of the framework is that it identifies architectural and knowledge-based requirements for agents to structure ontological models for cognitive profiling in order to increase cognitive awareness between themselves, which in turn promotes flexibility, reusability and predictability of agent behaviour. The ultimate aim is towards applications which advocate user-centeredness such that as little cognitive overload is incurred on humans. The Semantic Web is used as an action mediating space, where shared knowledge base in the form of ontological models provides affordances for improving cognitive awareness.

Based on the rationale and concerns described above, the objectives and a brief outline of the chapter presented in the next section.

OBJECTIVES OF THE CHAPTER

The following chapter will serve the following aims and objectives:

- Delineate upon the current limitations in the state of multi-agent collaboration in order to elaborate the rationale, need and the synergistic role of cognitive dimension to the Semantic Web with particular regard to distributed collaborations amongst agents
- Describe the conceptual constituents of a theoretical framework called Cognitive Model of Multi-Agent Action (COMMAA) derived from cognitive models in HCI to improve the state of multi-agent collaboration
- Detail upon the Design and Implementation of Semantic Representational and Ontological Models based on the theoretical principles of COMMAA that allow cognitive processing of an agents action using state of the art Semantic Web technologies
- Describe heuristic reasoning mechanisms that can be derived from cognitive models to enhance the cognition of Semantic Web agents
- Analyze and discuss the impact of using COMMAA to model multi-agent collaborative applications on the Semantic Web

BACKGROUND

The Semantic Web vision of Berners Lee (2001) has enabled the Web applications to move from a purely human user community towards a mixed user community consisting of humans as well as of software agents. This imposes certain challenges and brings new requirements towards models for modelling Semantic Web-based systems (Scott et al. 2005; Klein et al. 2004; Neuhold 2003). The foremost issue is that of adaptive collaborative coordination and cooperation for utilizing services and Web information and imposes challenges from the perspective of interaction as well as interoperability amongst both agents and humans (Arai & Ishida 2004). As software agents become more capable and more prevalent, they must be able to interact with a heterogenous collection of both humans and software agents, which can play diverse roles in a system, with varying degrees of autonomy, initiative, and authority across different tasks (Schreckenghost et al. 2002). However, research supporting such interaction with these types of agents has received relatively little attention (Martin et al. 2003a; 2003b).

Limitations in the State of Multi-Agent Interaction

While there has been a significant proliferation of agent architectures and applications in the Semantic Web domain, there is significant separation of concerns from the principles that ensure flexibility of distributed interaction between heterogenous agents. Recently, much effort has been expended on making agents interoperate in the emerging open environments and standards. The Foundation for Intelligent Physical Agents (FIPA), an IEEE Computer Society standards organization, has attempted to facilitate the interoperation and inter-working between agents across multiple, heterogenous agent systems (FIPA, 2007). A variety of FIPA-Compliant platforms have emerged (Luck et. al (2005) provide a review). Despite this effort, this goal has still not yet been achieved as Louis and Martinez (2005a) point out. In addition, the Agentcities European project (Willmott, 2003) which resulted in the deployment of a worldwide open testbed environment, underlined the lack of 'spontaneous' exchanges between agents running in this environment. In almost all cases, agents can only interact with agents they have been designed to interact with. One reason is that agents are implemented using mechanisms such that they conform to only a limited set of interaction protocols generally resulting in inflexible or rigid agents. It is reported in research and learnt from previous experience (Ahmad et al. 2005, Shafiq et al. 2005, Tariq et al. 2005a, Tariq et al. 2005b) that the agents show unyielding behaviour to messages not specified by the protocol. Efforts such as Louis and Martinez (2005a;2005b) have attempted to address the issues but the focus has been largely to provide semantic handling of messages.

It is therefore believed that there is still a long way to go before true homogenisation of agent communities can be achieved. This is because the variance of agent communication and functional pragmatics introduces a certain level of mismatch and the need of flexible and adaptive interactions that promote interoperation becomes imperative. This is particularly essential when the agents from diverse platforms intend to co-exist and cooperate in mutual. In addition, most agent-based applications assume pre-defined knowledge of agents' capabilities and/or neglect basic cognitive and interactional requirements in multi-agent collaboration. Thus the research community is faced with the challenges of improving the limited visibility of agent's processing ability and behaviours that may be a result of possible mismatches between the agents' mental and implementation models. In addition, it is claimed that inadequate adjustability of the agent's autonomy and a basic lack of compatibility between the required capabilities and those provided by an agent impose further research challenges (Martin et al. 2003a; 2003b).

Potential of Cognitive Models to Improve the State of Multi-Agent Interaction

Some interdisciplinary research has stressed the potential of cognitive models studied in cognitive science as substantial means of better probing multi-agent issues, by taking into account essential characteristics of cognitive agents and their various capacities (Sun 2001). The term cognitive models has traditionally been associated with humans as cognition is essentially a human characteristic. Cognition can be thought of as a modelling process which creates a model from which deductions can be drawn (Meredith 1970). Humans are known to continually create and access internal representations of their current situation - referred to as their cognitive model (Saja 1985). It is said that the state of interaction with a system can be greatly improved by design activities that account for and support the emergence of a user's cognitive model. These models are referred to as mental models in human-computer interaction (Norman 1986; 1988).

Inspired by the potential of cognitive models, the research presented in this chapter investigates the possibility of meeting the above mentioned challenges by bringing cognitive models and theories in the Semantic Web to achieve more robust and effective architectures for agents that facilitate distributed collaboration– be it amongst agents or between agents and humans or vice versa. The premise of the research is based on the hypothesis that if artificial (or software) agents were to be designed to emulate the interactional and cognitive properties of humans in a complementary way, such that they interact with each other and their environment in the manner that humans do, it would increase their functional capability to serve humans. Additionally it would also reduce the cognitive load that humans require in distributed collaborations while viewing it from a distributed cognitive perspective.

RESEARCH MOTIVATION AND CONTEXT: DISTRIBUTED COGNITIVE VIEW OF THE AGENT MEDIATED SEMANTIC WEB

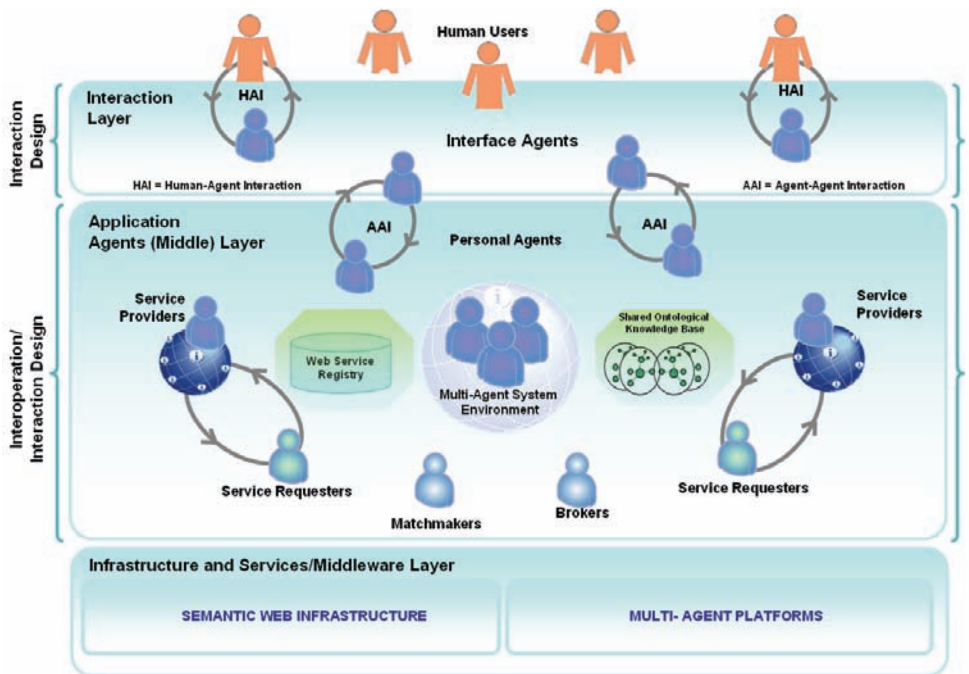
The view adapted for Semantic Web is that of a world-mediating system as it mediates between users and a part of the world, often by manipulating machine representations of the world (Clark, 2001). At the basis of this research is the idea to view the Semantic Web as a distributed cognitive system, a basic unit of analysis, composed of human and machine agents in a work domain that is delineated by roles, work and communication norms, artefacts, and procedures (Zhang et al, 2002).

According to (Lu, Dong & Fotouhi 2002) the Semantic Web uses ontologies to describe various Web resources, hence, knowledge on the Web is represented in a structured, logical, and semantic way allowing agents to navigate, harvest and utilise this information (Payne, et al., 2002a;2002b). Agents can also read and reason about published knowledge with the guidance of ontologies. Also the collection of Web-services described by ontologies like OWL-S (Ankolekar et al. 2001; Martin et al. 2005;2007) will facilitate dynamic matchmaking among heterogenous agents: service provider agents can advertise their capabilities to middle agents; middle agents store these advertisements; a service requester agent can ask a middle agent whether it knows of some provider agents with desired capabilities; and the middle agent matches the request against the stored advertisements and returns the result, a subset of the stored advertisements (Sycara et al. 2002;1999).

Based on the analysis of literature and state of the art, agent-mediated distributed computing paradigm for the Semantic Web is viewed as a layered abstract architecture shown in Figure 1 -a lens through which multi-agent collaboration can be viewed. Applying the distributed cognitive view of Semantic Web, the abstract layered model revises the traditional view of the Semantic Web by adding cognitively modelled interactions.

The above abstract model of the Semantic Web and agent characteristics requires multi-agent interaction which can consist of three interaction levels: human-human, human-agent, and agent-agent. In each interaction level, both interaction design and interoperability are necessary for

Figure 1. Layered Abstract Model for illustrating various levels of Cognitive Collaborations in Agent Mediated Semantic Web



mutual accessibility and understanding among them as has also been highlighted by Arai & Ishida (2004). The chapter extends the vision for the need and requirements for modelling these interactions from a distributed cognitive perspective (Basharat and Spinelli, 2008a). By applying the Distributed Cognition perspective Chandrasekharan (2004) this model considers the importance of studying interaction and interoperation amongst multi-agents not in isolation but within the environment agents inhabit. The combination of the Semantic Web inspired by cognitive model can generate a framework where agents and application can better cooperate.

After a review of the available cognitive approaches that model human activities in interaction with any system (artefacts and the environment), the Action Cycle (AC) (Norman 1986; 1992) has been selected as the most promising approach for this research. The aim is to unfold the potential of the AC in an attempt to identify the design and interactional gaps between heterogenous agents on the Semantic Web. The resulting contribution lies in the adoption of the AC to develop a heuristic modelling framework called COgnitive Model of Multi-Agent Actions (COMMAA).

The framework is proposed to model multi-agent actions in a collaborative MAS environment from a cognitive perspective. The framework is intended to aid the designer in modelling the agent behaviour and action through a cognitive cycle. Using the principles of the proposed framework designers can define both functional and non functional aspects of the design of an agent's interactive role in a collaborative scenario, especially focusing on the concepts of semantic and articulatory distances, as derived from AC, as mismatch between agents' goals and its functional capabilities.

Not only this research proposes the theoretical guidelines for cognitive modelling of agents, it also provides design illustration for the architectural elements necessary for realizing these principles in the Semantic Web context. Thus the framework identifies architectural and knowledge-based requirements for agents to structure ontological models for cognitive profiling in order to increase cognitive awareness amongst agents. By cognitive awareness, a term coined within this research, it is intended the ability of the Web agents to diagnose their processing limitations and to establish interactions with the external environment (in the form of other agents including humans and software agents) using the principles derived from the framework for COMMAA. This is with the aim to support users' goals in a more direct manner by providing agents that can share, discover and access each other's capabilities in a collaborative manner and are able to function dynamically and adaptively without continuous human intervention.

This brings about a more effective MAS environment; where agents may delegate each other tasks and goals based on each other's awareness of abilities, behaviours and affordances. The ultimate aim is towards applications which advocate user-centeredness such that as little cognitive overload is incurred on humans. The strength of this framework lies in its robust theoretical foundation that has found validation in a developmental infrastructure that helps realise the theoretical principles.

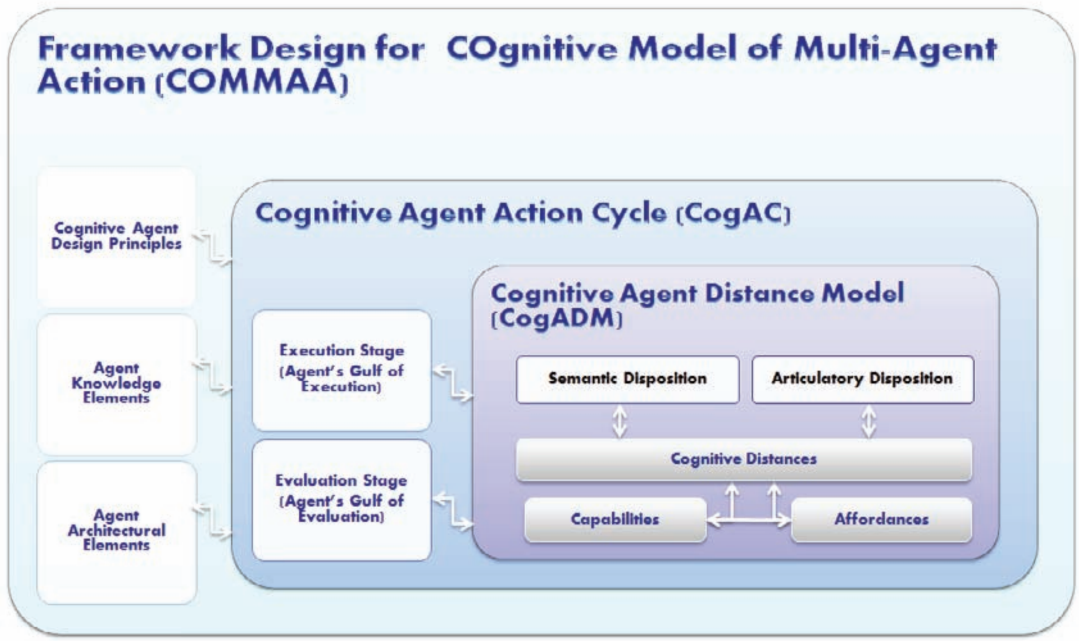
THEORETICAL FRAMEWORK AND CONCEPTUAL CONSTITUENTS FOR COGNITIVE MODEL OF MULTI-AGENT ACTIONS (COMMAA)

The framework developed in this work and presented below is based on these fundamental principles of Agents' action, borrowed and modified from the Human Action Cycle (Norman 1986) and its elaboration for Direct Manipulation Interfaces by Hutchins et al. (1986). The framework of COgnitive Model of Multi-Agent Actions (COMMAA) is shown in the Figure 2. The primary aim of the framework is to cognitively model the agent's action in a collaborative MAS environment situated in the Semantic Web such that the limitations in the state of Multi-Agent Interaction can be overcome.

The conceptual constituents of the framework of COMMAA include:

- **Cognitive agent Action Cycle (CogAC):** COMMAA is based on Cognitive agent Action Cycle (CogAC) which serves as the fundamental core of the framework, and is designed to aid the designer elaborate the agent's functional behaviour using two stages namely Execution and Evaluation, each with its respective steps. The CogAC views agent as the primary entity that interacts and functions in a MAS environment. The stages of an agent interacting with a MAS environment are described such that in order to accomplish a goal, which is in turn delegated to it by a human user, the following steps are traversed by an agent: Goal Formation, Intention formation, Action specification, Execution, Perception, Interpretation and Evaluation.
- **Cognitive Distance Model (CogDM):** The further elaboration of the steps of CogAC leads to the formulation of agent's semantic and articulatory disposition in each stage of execution and evaluation, described and illustrated by the Cognitive Agent Distance Model CogADM. These dispositions also help to identify the agent's Gulf of Execution and Evaluation. These two are discussed in the subsections to follow.
- **Cognitive Agent Design Principles:** The principles are derived using the Action Cycle mapped for agents. The principles may serve as heuristic for evaluating the design of agent-based applications. They help to identify the significant mismatches, constraints and affordances. The framework

Figure 2. Conceptual design of Theoretical Framework / Conceptual Constructs of COMMAA – Cognitive Model of Multi-Agent Action



defines CogADPs only at abstract level. These serve as blueprints which may be specialised to a domain specific context by the designer to derive a context specific cognitive profile for an agent. These may be specialised according to the domain knowledge and the specific contexts of application the agent may be operating in. The design principles aid in Cognitive Mismatch (Distance) Analysis, that allow at design time to be made known the possible stages where distance of execution or evaluation may occur. The designer by analyzing whether provision for these principles in made in the agent's infrastructure can help develop the cognitive profile of the agents, alternatively agents may have the dynamic capability of identifying these distances at runtime and may change, update their profile dynamically.

- **Agent Architectural Elements:** As each sub-stage of agent's execution and evaluation stages are elaborated, and as distances are identified, it helps in identifying the architectural needs and components required for successful completion of agent action cycle. As these are identified by the designer, they may be cross checked against the environment that the agent in being built using. In other words, it may also be said that provision of these capabilities ensure that the agent's Cognitive Design Principles will be met to some extent. The availability of these elements would ensure that the agent is Cognitively Directed, or Cognitive Directness is exhibited in agent's action with respect to its interaction with the environment. The Architectural elements identified ensure the minimal design requirements that must be met in order to bridge the agent's gulfs of execution and evaluation.
- **Agent Knowledge Elements:** The knowledge requirements are identified by the designer such that at each stage of agent's execution and evaluation, these are the elements that the agent must possess or must

be provided with in order to achieve the successful realisation of the respective stage.

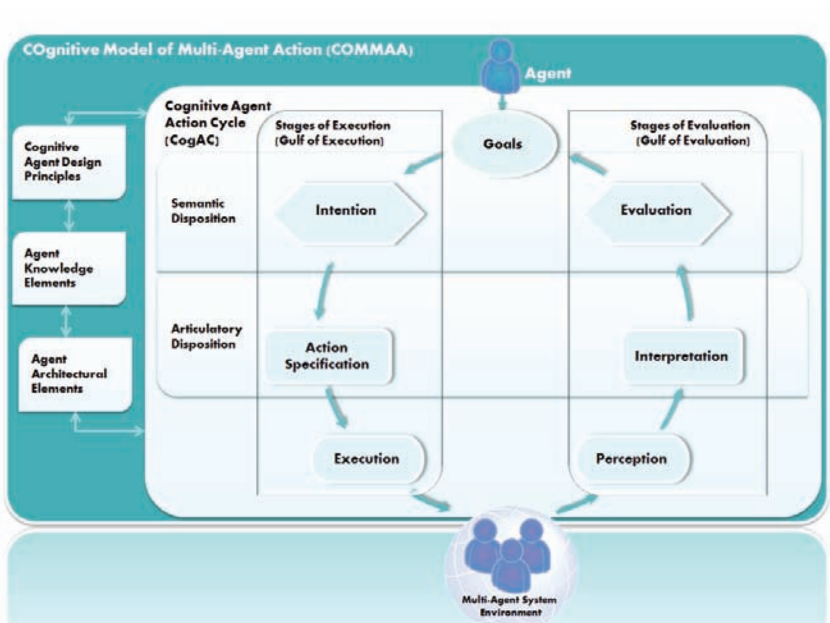
Cognitive Agent Action Cycle (CogAC)

Agents are designed to continually act upon and monitoring the MAS Environment, interacting with it and collaborating with other agents and entities, evaluating its state, and executing actions. The system is a closed loop: when agents act, it is usually done so in response to some prior evaluation of its perceptions or as a result of some goal delegated to it by a human. After an agent acts, it evaluates the impact of the executed act, often modifying the action as it carries it out. In MAS environment the fundamental unit of agent's social ability is its interaction with other agents using messages in Agent Communication Language (ACL). Agent's Interaction is modelled to have two stages as shown in Figure 3. The Interaction will have some Goal i.e. the objective that needs to be achieved using the interaction. In order to achieve this goal, agent will need to go through the two stages namely Execution and Evaluation in order to successfully achieve the goals of the interaction respectively.

The stages of an agent interacting with a MAS environment are described such that in order to accomplish a goal, which is in turn delegated to it by a human user, the following steps are traversed by an agent: Goal Formation, Intention formation, Action specification, Execution, Perception, Interpretation and Evaluation (as shown in Figure 3.). The essential concepts are the Gulfs of Evaluation and Execution, each arising as a result of semantic and articulatory distances (cognitive distances in general). The relevance of these concepts to the agent domain is formally described in the next sections in the form of Cognitive Agent Distance Model, which are detailed further.

The inter-relationship between the CogAC, its stages of execution and evaluation, the semantic and articulatory dispositions and other elements of COMMAA is schematically shown in Figure 3. In Table 1 and Table 2 these stages are elaborated. In addition, a generic view of the corresponding CADPs, Knowledge Requirements and archi-

Figure 3. High-level conceptual design of CogAC in relation to other constructs of COMMAA



tectural needs are also identified. Together with these main components, the three additional components are identified to help the designer model agents' behaviour in a more robust manner. Cognitive Agent Design Principles, Agent Architectural Elements and Agent Knowledge Elements are all identified, as each stage of the agent's execution and evaluation are elaborated upon.

Cognitive Agent Distance Model (CogADM)

On the Semantic Web, Knowledge is invisible and intangible. While meanings are essential to knowledge, they cannot get across to an agent without some kind of representational form. Knowledge representation has two aspects: the meaning of the information, named semantics, and the physical form or appearance, named syntax. When an agent interacts with a knowledge representation, it interacts with both the semantics and the syntax.

There is often, however, a gap, known as Cognitive Distance, between the knowledge an agent needs and the manner in which this is represented in its environment, as shown in Figure 4. This manner of representation also includes the mechanisms with which the knowledge is accessed and reasoned about.

The prospective relevance of the cognitive distances is highly relevant to Communication, collaboration and interactions taking place between agent application residing on the Semantic Web - since the basis of interaction is the communication language and its vocabulary represented as knowledge on the Semantic Web.

Cognitive Distance in this context is taken to be a measure of the gulfs of execution and evaluation

—the conceptual gap, or mismatch between the agent's goals and intentions, and the way in which they are in cohesion to, or represented by, the multi-agent system environment. A large distance is representative of a large gulf in the execution or evaluation stages, signifying that a lot of cognitive load is incurred in translating the

Table 1. Steps of CogAC in Execution Stage (Agent's Gulf of Execution) cross referenced with design principles, Knowledge elements and Architectural requirements

Steps of CogAC	Description	Cognitive Agent Design Principle (CADP)	Agent Knowledge Elements	Agent Architectural Elements
Execution Stage (Agent's Gulf of Execution)				
Step 1: **Form Goal**	•An Agent's Goal is the state the agent wishes to achieve	•Compatible goal formation •Intention formation •Agent must have the capability to express goals to desired intentions •Semantic Distance Occurs if the capability is not provided to the agent. •Agent is being required to work at lower level of detail, resulting in greater semantic distance	•Task Knowledge Domain knowledge: Appropriate Situation •Affordance for Goal Representation and Formation •Affordance for Expressive Power and Communication	•Goal Representation •Goal to Intention Formulator •Task Representation •Domain Knowledge Representation •Intention Representation
Step 2: Form/ Specify Intentions	•An intention is the decision to act so as to achieve the goal	•Exhibits Semantic Directness of Interaction with the Environment (Disposition of Agent is Semantically Direct wrt its execution of its interactions in the given environment) •Functional Capability for Intention Formation	•Task Knowledge : intention details	•Content Representing the intentions, as rules or some construct •Heuristic Reasoning needed for Analysis of Functional Capabilities and Semantic Directedness
Step 3: **Action Specification**	•The process (mental) of determining the logical representation of the actions that are to be executed by the agent on the mechanisms of the system (MAS environment) •Action must be taken with respect to the environment the agent is operating in	•Constraints imposed by the environment or the world of the agent must be taken into account •Articulatory Directedness (Disposition of Agent is does not posses any Articulatory distance wrt to execution of its actions in the given environment) •Affordance for Action	•Task Knowledge : Action Details •Domain •Environment Knowledge: Constraints (e.g. Representational)	•Actions Represented as some protocol e.g. Conversation Protocol or Interaction/Negotiation Mechanism •Heuristic Reasoning needed for Analysis of Affordances available and determining the Articulatory directedness
Step 4: **Execution**	•Agent executes the tasks formulated as a result of action specification	• Using the MAS Environment and the middleware to execute its actions	• Knowledge of Execution Mechanisms	•MAS Middleware, Execution Framework, Control Mechanism for Agent's Execution

Table 2. Steps of CogAC in Evaluation Stage (Agent's Gulf of Evaluation) cross referenced with design principles, Knowledge elements and Architectural requirements

Steps of CogAC	Description	Cognitive Agent Design Principle (CADP)	Agent Knowledge Elements	Agent Architectural Elements
Evaluation Stage (Agent's Gulf of Evaluation)				
Step 5: **Perception**	•Perceive the output, response of an event, a trigger or a message	• Affordance for perceiving the state of the environment	•MAS/Platform Knowledge: •Constructs, Content, Protocols	•Means of Feedback Specification •Means of Perception
Step 6: **Interpretation**	•The relationship between the state of the MAS environment and the goals of the agent can only be determined by first translating the environment state into psychological states for the agent then interpreting the perceived environment state in terms of agent's variables of interest.	•Articulatory Directedness (Disposition of Agent does not exhibit Articulatory distance wrt to evaluation of its actions and the response of the environment) •Affordance for Reasoning •Affordance for extracting the required meaning from interaction output •Affordance for Interpretation of Feedback of the Interaction	•Domain Knowledge : Expected effects	•Means of Interpretation •Reasoning Mechanism for Interpretation •Logic Mechanism •Feedback Means •Means to Recognize and Interpret Feedback •Interpretable effects
Step 7: **Evaluation**	•Evaluation of the environment state requires comparing the interpretation of the environment state with the desired goals. This often leads to a set of new goals and intentions.	•Agent's Functional Capability for Evaluating the Outcome to determine if the goal has been achieved and to determine if it possesses the means to predict the outcome •Semantic Directedness (Disposition of Agent is Semantically Direct wrt to evaluation of its actions and the response of the environment	•Task Knowledge : expected effects •Expected Feedback	•Logics based on which Evaluation is to be carried out •Heuristic Logics •Representational Logics •Expectation Means •Predictability

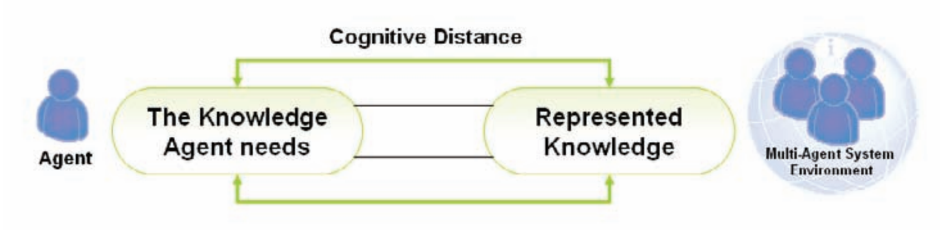
agent's intentions into the system's representations, or vice versa.

That is, a large distance of execution means it is relatively difficult or not possible for the agents to express their query or desires to the system, and a large distance of evaluation indicates mismatch of some form within the agent's infrastructure to interpret or evaluate the system's output or response as a result of some interaction with it.

Directness of Agent's Interaction with MAS Environment

Using the directness of interactions as usability measures would involve understanding the agent's

Figure 4. Cognitive Knowledge Gap between agent and multi-agent system environment



problem solving strategies, approaches and intentions as now well the MAS environment supports the agent's functional needs. A design and evaluation methodology that assesses directness requires cognitive basis because understanding the user's mental processes is key to assessment. The concept of directness as suggested by (Hutchins et.al, 1986), and later by (Cuomo 1993) is adapted here to refer to the degree of capacity of an agent to bridge the Gulfs of Execution and Evaluation.

The concept of multi-agent interaction is virtually an unexplored area in terms of operationally defining and assessing the directness of interactions an agent engages in with its MAS environment to a degree that can be applied in practice and measured using qualitative or quantitative tools. Directness of an Agent's Interaction with its environment may be used as a qualitative indicator of the amount of cognitive processing needed to carry out a successful interaction. Directness is inversely proportional to the amount of cognitive processing it takes to manipulate and evaluate the results of agents' interaction with its MAS environment. Moreover the cognitive processing required for an agent is a direct result of the gulfs of execution and evaluation the agent has to deal with. The better the agent's architecture, the less cognitive processing needed and the more direct the resulting interaction between agents.

Thus Distances are complementary to Directness; the lower the distances, the greater the directness, and vice-versa. The two terms distance and directness may be alternatively used, depending on the nature of mismatch or the extent of gulf in the stages of agent action. It would be subsequently shown in the later sections how these concepts are encoded into the profile of agents and how the concepts are important to derive heuristic mechanisms for agents' reasoning.

Applying the Gulfs of Execution and Evaluation in Multi-Agent Environment

In order to identify gaps that separate agents mental states from execution ones, the agent's gulfs of execution and evaluation must be detailed as below:

Agent's Gulfs of Execution: The gulf of execution arises as a result of cognitive distances of execution between the agent and its interaction with the environment (multi-agent, open). The gulf can be identified by elaborating the cognitive distances of execution – which result due to the difference or mismatch between the intentions and the allowable, available actions, capabilities and affordances in its environment. One indicator representing this gulf is to determine how well the agent is able to do the intended actions directly, without extra effort: is the agent able to fulfil its goals delegated to it by humans? Do the actions provided by the agent match those intended by the person? Does the environment/infrastructure (internal infrastructure and/or external environment) provide affordances that allow for the intentions of the agent? If there is a limitation, then there is a gulf of execution in the state of agent's interaction which must be bridged, either with collaborative effort with other agents in the environment or eventually by the human, who would incur cognitive overload or processing. The ultimate aim is to design agents that are able to readily identify and bridge/overcome such a gulf to efficiently achieve the goals set up for them.

Agent's Gulfs of Evaluation: The gulf of evaluation arises as a result of cognitive distances of evaluation between the agent and its interaction with the environment (multi-agent, open); the possible mismatches between agents reasoning capabilities and its representation mechanisms. The Gulf of Evaluation reflects the amount of effort that the agent must exert to interpret the state of its interaction with the system and to determine how well the expectations and intentions have been met. The gulf is smaller when the system provides information about its state in a form that is easy to get, is easy to interpret and matches the manner in which agents' affordances allows these to be perceived.

Bridging the Gulfs and the Cognitive Distances

Directness is inversely proportional to the amount of cognitive effort/processing it takes to manipulate and evaluate the state of interaction with MAS Environment and, moreover, the cognitive effort is a direct result of the gulfs of execution and evaluation. The better the architecture and the environment of the agent helps the agent bridge the gulfs, the less cognitive processing needed and the more directed the resulting interaction. For this, the architecture should facilitate some means of identify, through some indicators, the possible distances and also identify the capabilities and affordances available and not-available corresponding to these indicators.

Agents' Capabilities and Affordances

The concept of affordance is here explored and exploited. It is believed that an affordance inspired agent architecture and environment will help to bridge the gulfs of execution and evaluation. By interfacing perception and action in terms of capabilities and affordances for agents, the aim is to provide a new way for reasoning about agent's capacities and bring about cognitive awareness amongst the agents about each others capacities and constraints, when interacting in a collaborative environment. In Cognitive Science, an affordance is a resource or support that the environment offers an agent for action, and that the agent can directly perceive and employ (Gibson, 1979). Although, this concept has only rarely been used in Semantic Web agent architectures, it offers an original perspective on coupling perception, action and reasoning, differing notably from standard reactive and hybrid architectures. Taking it literally as a means or a metaphor for coupling perception and action directly, the potential that affordances offer for designing new powerful and intuitive agent-based Semantic Web architectures is obvious (Vugt et al. 2006).

The term affordance is adapted for COMMAA to refer to the agent's capacity of action. At each stage of the agent action cycle the agent's corresponding affordance is determined and accounted for. Any constraint in any of the agent's capacities, being the ability to achieve the goal, to formulate the intention or to interpret the consequences of its action, may result in a cognitive distance being introduced. Usually the term affordance is linked to a machine or an application (Norman 1992). In the context of this research affordance is the ability of one agent (the sender) to behave in a way that the other agents in the MAS environment(the receiver) can understand, such that they both have a shared mental model and can trigger, complement or facilitate each other's action/behaviour; therefore these affordances need to be ensured. The affordances are provided by the cognitive artefacts that form part of the agent's internal infrastructure/architecture and its external environment.

Affordances are the opposite concept to distances, so they are complimentary. For instance, an agent's affordance for intention formation will ensure there is no semantic distance of execution and a semantic distance of execution will mean that agent has no affordance for forming an intention. The psychologist Gibson was the first to frame affordances as unified relations between the environment and an actor (Gibson, 1979, p. 127). Affordances can be explained as action possibilities that actors have in the environment. That is, an affordance exists relative to (1) properties of the environment and (2) the action capabilities of an actor (McGrenere and Ho, 2000). For example, a chair has the affordance of 'sitting', because of its shape, height and carrying capacity and because of the humans' ability to sit, the length of their legs, and their weight. The concept of affordances is of particular interest in the field of HCI, which primarily concerned is studying how properties of computers (the environment) and humans (actors) influence their interaction with each other.

Extending the affordance concept to the Semantic Web, it is believed that by semantically identifying and encoding the affordances of an agent will help achieve cognitive directness of interactions amongst the agents. This will contribute to making agents more interoperable in open and heterogenous environments. Some considerations that must be taken into account include the relationship of goals with respect to agents. Goals are central in affordance evaluations. It is important to understand that an affordance does not change as the needs and goals of the person change (McGrenere & Ho, 2000 interpreting Gibson, 1979). Similarly, for an agent, an affordance must be identified irrespective of what the agent's eventual goals are. E.g. ff an agent affords Message translation from FIPA-ACL into FIPA-SL, it is independent of whether another agent will eventually participate in such interaction where this translation is required. However, agent's actions do depend on the goal context. Agents will typically need to act within the environment (they use an affordance) because of a goal they want to achieve for example, performing a task (Vugt et al. 2006, Kakazu & Hakura 1996).

Semantic and Articulatory Distances in Multi-Agent Interaction Model

Following is a detailed account of how may the components of cognitive distance namely: the Semantic and the Articulatory distances occur in the execution and the evaluation cycles. It is also important to illustrate how the cognitive distances are identified with the help of agents' capabilities and affordances. A conceptual high-level view is shown in Figure 5. Identifying these distances, along with agents' capabilities and affordances is of primary importance in highlighting the possible gulfs of evaluation and execution.

- **Semantic distance:** The degree to which the semantic concepts used by the agent are (1) compatible with those of the other agents (including humans if the interaction is being carried out with a human) and, (2) can be used to easily accomplish the agent's goals
- **Articulatory distance:** The degree to which the form of communication between an agent and its environment reflects the application objects and tasks involved

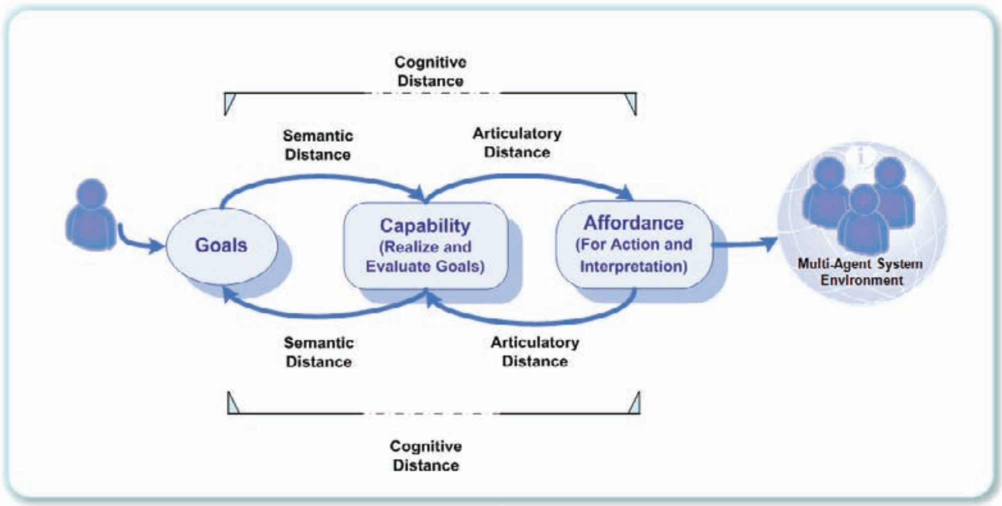
Articulatory distance concerns the actual form that communication takes between say two agents; for example, the choice of Message Encoding, Message Content, Content Type, Interaction Protocol used/employed for the communication. A small articulatory distance results when the input techniques and output representations used are well suited to conveying the required information. Articulatory distance is also decreased when the form of inputs and outputs relate to the semantic concepts used of the underlying conceptual model.

Semantic distance involves the capability of agents required to express desired actions within the concepts of the system. It deals with the possibility to express the concepts of interest concisely using the available capabilities. Semantic distance also involves a measure of how closely the agent's conception of the task domain matches that of the environment. The two distances that compose the Cognitive Distance in Agent's Behaviour are the Semantic Distance and Articulatory Distance. These can be considered as subsets of each of the gulfs, but in reference to input behaviour (initiator's behaviour in communication/interaction) and output behaviour (Respondent's behaviour in communication/Interaction). These are illustrated and discussed in depth below.

An Illustration of Semantic Distance of Execution

Semantic Distance relates to the relationship between an agents intentions and the meaning of expressions, required to convey the agents'

Figure 5. Components of cognitive distances in multi-agent collaboration



intention such that its meaning is interpretable by the intended recipients in the environment. Semantic distance is related to the 'nouns' and 'verbs' or 'objects' and 'actions' provided by an agent's infrastructure and its environment. For execution, forming an intention is the activity that spans semantic distance. The intention specifies the meaning of the input expression that is to satisfy or reach the' agents goal or sub-goal.

If *semantic* indirectness of *execution* existed, agents would not be able to express their intentions directly, or at all in order to achieve the goal delegated to them. Lack of capabilities or affordances would be indicators of this condition. Agent is programmed at lower level of functionality then desired by the human user. The agent or the human may need to carry out more actions then would be expected to accomplish the same goal or intention. E.g. Agent may need to collaborate or request another agent to achieve the goal on its behalf. This requires agent to have desired affordances and capabilities defined. The semantic distance of execution is illustrated in more detail in Figure 6.

An Illustration of Articulatory Distance of Execution

Whereas semantic distance relates to relationships between Agents' formulated intentions and the meanings of expressions/functional capabilities available, articulatory distance in an agent context is defined to relate to relationships between the meanings of expressions/capability and the agent has the affordance to realise the capability in action, or whether agent affords the actions that are essential in achieving the desired intentions. A mismatch of such a form will cause an articulatory distance of execution to exist. The articulatory distance of execution is illustrated in more detail in Figure 7.

An Illustration of Semantic Distance of Evaluation

Semantic distance also occurs on the evaluation side of the interaction cycle. Semantic distance of evaluation is proportional to the amount of processing required by the agent to determine whether the goal has been achieved. The semantic

Figure 6. An illustration of agent's semantic distance of execution

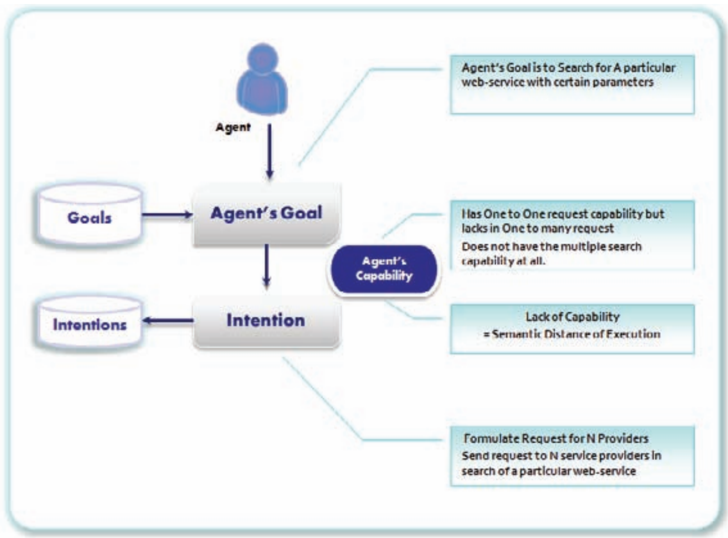


Figure 7. An illustration of agent's articulatory distance of execution

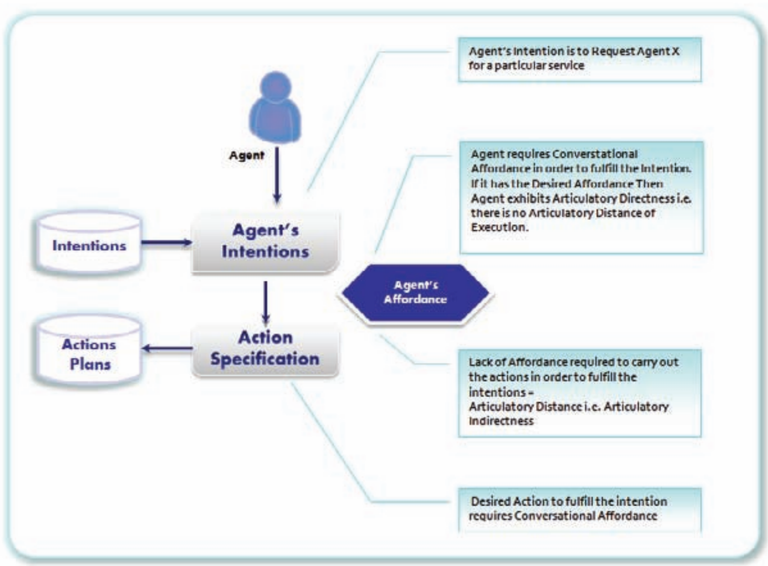

Figure 8. An illustration of agent's semantic distance of evaluation

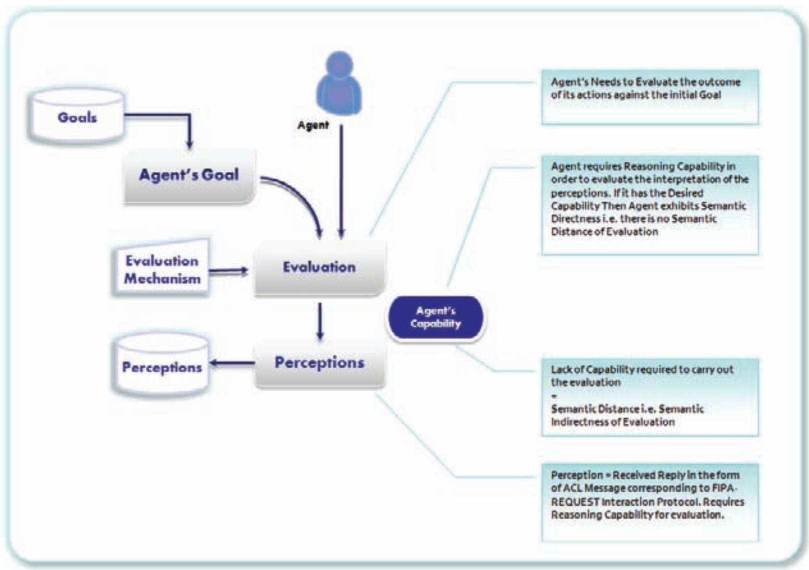


distance of evaluation is illustrated in more detail in Figure 8.

An Illustration of Articulatory Distance of Evaluation

Articulatory distance or indirectness of evaluation would be indicated by errors in interpretation and having to take extra actions to correctly interpret the state of communication or the result of interaction. An agent's inherent articulateness is closely tied to its level of technology. The articulatory distance of evaluation is illustrated in more detail in Figure 9.

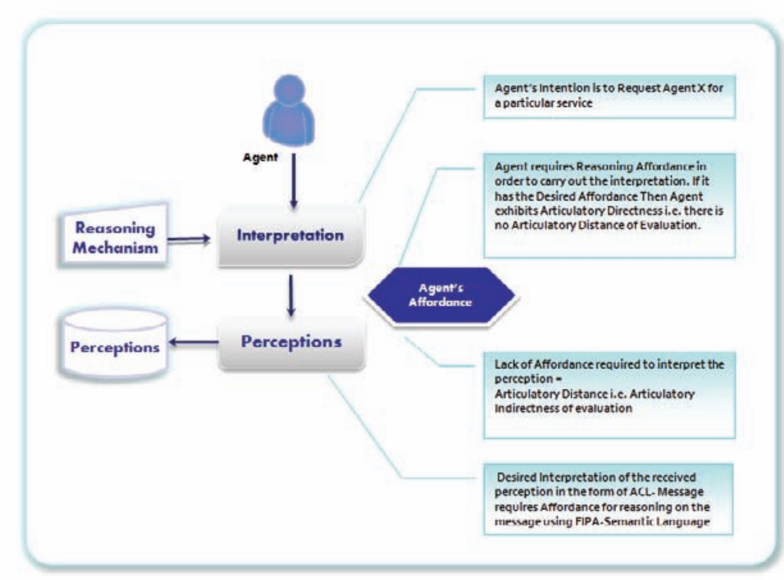
DESIGN AND IMPLEMENTATION OF COMMAA INSPIRED AGENT ARCHITECTURE

Design Goals for Cognitive Profiling of Agents

The theoretical foundations of Cognitive Models such as the Action Cycle (AC) bring about important implications in the current Semantic Web architectures. Traditional Web-service agent architectures only allow agents to discover about each others services. However this research claims that an architecture that is inspired from cognitive models would allow the agents to develop a cognitive awareness about each other which could bring to a more effective MAS environment. To validate this claim, a lower-level classification of design goals which provide the basis upon which the Cognitive Profiling Architecture is devised upon includes: (a) Enhanced Negotiation and Collaboration based on Cognitive Awareness (b) Flexibility and Reusability (c)Adaptive Interaction and Interoperability (d)Discovery based on Heuristic reasoning and (e) Minimization of cognitive load on humans.

In an attempt to realise the above design goals, which are direct implications of COMMAA, some important considerations are taken into account. Firstly, some mechanism is needed that enables the agents to discover and find out about each others cognitive distances, semantic and articulatory dispositions, capabilities, affordances and constraints. Secondly, dynamic and built in

Figure 9. An illustration of agent's articulatory distance of evaluation



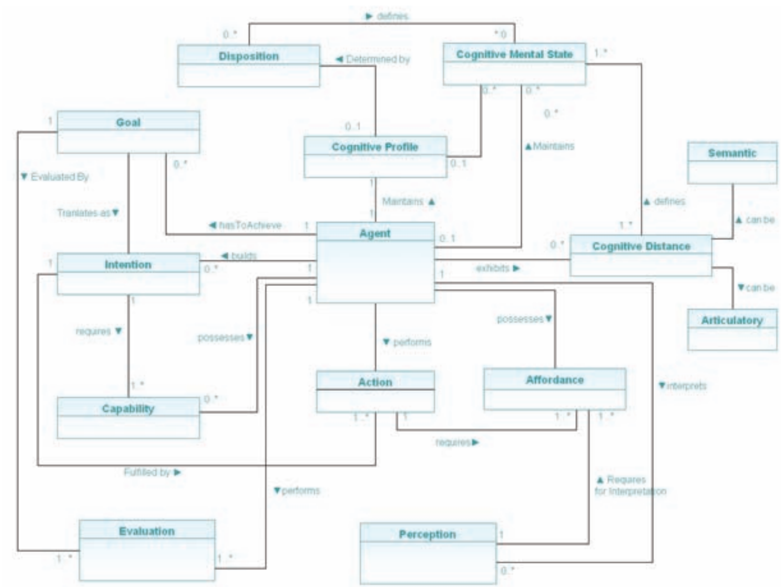
mechanisms are needed for heuristic reasoning and invoking/developing learning, adaptive measures for these constraints and distances to be bridged. These considerations are considered rudimentary to enable agents to be aware of these limitations and Gulfs that may limit their functionality or the extent of services they can provide. As minimal architectural consequences, the elements necessary in COMMAA inspired semantic-Web agent architecture are implemented in a cognitive profiling architecture described in Basharat and Spinelli, (2008b.). The Cognitive Profile of Agents is detailed next.

A Semantic Representation Model for Cognitive Profile of Agents

A possible way of implementing the cognitive profile is by associating an ontology with an agent i.e. agent is given knowledge about its constraints and affordances, its semantic and articulatory disposition. At the heart of the framework is the adoption of ontology to drive the cognitive profile of agents. From a philosophical perspective ontology can be defined as a set of things whose existence is acknowledged by a particular theory or system (Honderich, 1995 cited in Bell et al. 2007). Such 'things' include both types (such as the class of Agents) and individual elements (such as the agent TravelAgent). The adoption of such a definition is important because, when compared with more computationally orientated definitions of ontology (for example, (Gruber 1993); p.1) states that "an ontology is a specification of a conceptualisation"), there is an explicit reference to a system's ontic commitment (i.e., things whose existence is acknowledged or recognised). This leads to representations that are more closely mapped to real world objects.

The use of ontology is also prospective in the Semantic Web action space, since the emerging standards enable reasoning to be carried out effectively on such models. An ontology based reasoner could be invoked on the ontology to carryout reasoning using the heuristic reasoning rules defined; agent could then be made to reason about its state of processing according to CogAC. Architectures that facilitate the sharing of ontologies would enable the agents to discover each other cognitive dispositions thus improv-

Figure 10. Conceptual Model of Ontological Knowledge Model for Cognitive Profile of Agents



ing the manner in which they interact. The issue at stake is to be able to represent the cognitive profile adequately and in a manner that can be shared among agents. The Cognitive profile is therefore implemented as an Ontology in OWL, with OWL-DL (Description Logics) as basis of representation of the profile parameters and properties. Being an emergent standard, OWL-DL ensures that the model caters for a more open community. Ontologies have been recognised by the research community as a – model of expressing the knowledge model for agents e.g. by the recent research of (Laclavík et al. 2006).

Conceptual Model for Agents' Cognitive Profile Ontological Model

Figure 10 shows a generic conceptual model, with objects and properties (shown by labels on associations between concepts) of the ontological model to be implemented in order to enable shared cognitive profiling of agents.

Cognitive Profile of Agent

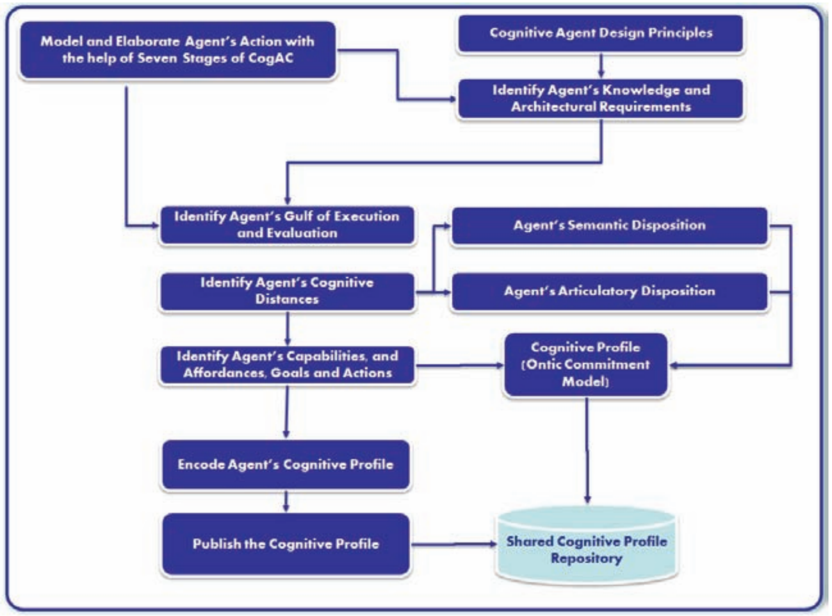
The framework's correct implementation calls for maintaining a cognitive profile of Semantic Web agent. Following are the elements to be maintained in the cognitive profile:

- Agents Cognitive Mental States
- Capabilities
- Affordances
- Semantic Disposition (Semantic Distances of Evaluation and Execution)
- Articulatory Disposition (Articulatory Distances of Evaluation and Execution)
- Goals, Intentions, Perceptions, Evaluations

Cognitive Mental State of an Agent

An agent modelled along the lines of the CogAC requires various cognitive mental states corresponding to the various steps in the execution and

Figure 11. Conceptual Flow of Activities to develop an application according to the guidelines of COMMAA



evaluation stages of the action cycle. These mental states of the agent facilitate the agent's behaviour in both its execution and evaluation cycles. It provides provision for state modelling, representation and tracking an agent's state of execution. In addition representing these states agents may have the dynamic capability of identifying these distances at runtime and may change and update their profile dynamically. The conceptual model is developed using the Protégé Ontology editor to generate OWL Ontology.

Modelling Agents Using COMMAA

In order to utilise COMMAA in practice to process and analyse the interactions and tasks of an agent, the process shown in Figure 11 is used during the design and development process of an agent-based application. The figure also summarises the components and principles that contribute to the agents state modelling, based on the principles of COMMAA. The process is described in detail in Table 3.

Abstract Heuristic Reasoning Mechanism for Agents

To bridge the gulfs of execution and evaluation, agent must have some heuristic reasoning mechanism built into its architecture, such that given a shared cognitive profile is available, it should be able to reason on the knowledge present in it to aid the agent's processing and help bridge the gulfs of execution and evaluation through collaboration or other means. The important considerations are with regards to the representation, discovery and reasoning of the cognitive distances. Rules generate advice by defining the combination of agent knowledge, action stages, distances, abilities/capabilities, and affordances, typically with the generic format shown in Figure 12.

Heuristic Reasoning Mechanism for Agents Execution Stage

The encoding of agents cognitive distances requires a reasoning mechanism. The reasoning is carried out based on the Semantic and Articulatory

Table 3 . Description of Activities in processing agents' action through COMMAA with input and output artefacts

Activities	Description	Input Artefact	Output Artefacts
Cognitive Modeling of Agent Behaviour	▪ Model Agent's Action using the CogAC ▪ The agent's behaviour is programmed according to the stages described in the CogAC ▪ Elaborate Agent's Action with the help of Seven Stages of CogAC ▪ Identify agent's knowledge requirements and elements ▪ As the knowledge elements needed by the agent are identified, it is ensured that the architecture of the agent provides for these knowledge elements to ensure a successful completion of the CogAC ▪ Program agent's behaviour according to available architecture	▪ Agents Functional Requirements ▪ Agents Knowledge and Representational Constraints ▪ Cognitive Agent Design Principles. The CADPs are used as heuristics to evaluate the design at each stage	▪ Knowledge Requirements
Scoping the Agent's Cognitive Profile	▪ Identify Agents capabilities capacities and affordances ▪ Identify agents cognitive distances ▪ Identify known possible agent's gulf of execution and evaluation ▪ Each of the components of the Agent Profile are interpreted such that they represent its Ontic Committment	▪ Knowledge Requirements ▪ Agents Functional Requirements ▪ Agents Knowledge and Representational Constraints	▪ Individual Agent Cognitive Profile (Ontic Commitment Model)
Encoding of Cognitive Profile	▪ Encode Agent's Cognitive Profile parameters in the ontology ▪ The Disposition of Agent (Semantic and Articulatory) in both stages of execution and evaluation is encoded at design time	▪ Profile Parameters ▪ Agents Semantic Disposition ▪ Agent's Articulatory Disposition	▪ Cognitive Profile ▪ (Ontic Commitment Model)
Sharing the Cognitive Profile	▪ Registering or Publishing the profile	▪ Cognitive Profile	▪ Shared Cognitive Profile Repository populated with Cognitive Profile of Agent

disposition of agents encoded in their Cognitive Profile. A reasoning mechanism for the execution stage in the form of pseudo-code is given in Figure 13. This is generic given that the action cycle is applied in a generic context. It may be specialised according to the agent application being developed.

Heuristic Reasoning Mechanism for Agent Evaluation Stage

A reasoning mechanism for the evaluation stage in the form of pseudo-code is given in Figure 14.

Figure 12. Generic Format for Rule-based reasoning of agents' cognitive mental states

           - Assert Cognitive Profile
          - Reason
          //Analyze semantic profile
          if (hasSemanticDistance)
          {
          reviseGoal(g);
          startCogAC(g);
          }
          else {
                    IntentionSet  is = getIntentionFromGoal(Goal g);
                    //Analyze Articulatory Dispostion of Execution
                    if(hasArticulatoryDistance)
                    {
                    attempt to overcome/bridge using available affordances
                              else
                    search Shared CognitiveModel
                    }
          }
}
```

Recursive nature of Cognitive Agent Action Cycle

CogAC, when applied in practice is essentially recursive in nature. A high level Goal can be functionally decomposed into sub-goals. Or, an action specification as a result of intention formation to achieve a certain goal may in turn specify other sub-goals to be achieved, for which the CogAC may be recursively invoked.The same recursive behaviour is also true in the evaluation stages. The desired interpretation of the received perception or evaluation may in turn require some internal goals to be achieve.

DEMONSTRATION OF AGENTS' ENHANCED COGNITIVE CAPABILITIES

In order to give a flavour of how the framework presented above enhances the agents' cognitive capabilities by imparting improved cognition, the framework was applied to a simulated multi-agent based distributed collaborative application with the aim of testing, improving and evaluating the framework. The purpose of this distributed collaborative multi-agent application is as follows:

- To show how the framework is applied to design of MAS based applications operable on the Semantic Web
- To show how application of COMMAA helps build the cognitive profile of the Agent
- Show how sharing the cognitive Profile improves the collaboration between Agents

Figure 14. Abstract Mechanism for Heuristic Reasoning of the Cognitive Profile Model (Evaluation-Sub Stages)

```

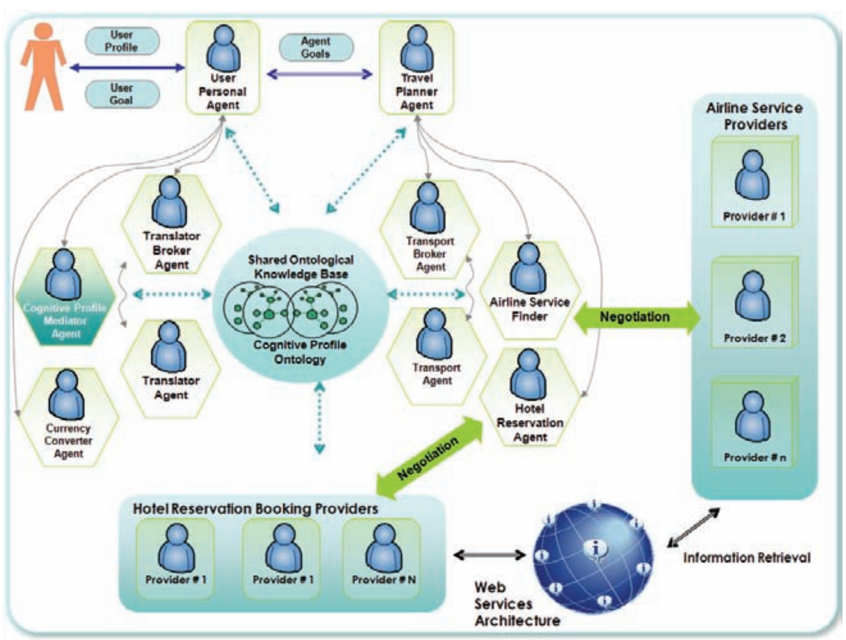
            }
            Else{
                        interpretPerception(P);
                        if(hasSemanticDistance){
                        Goal g = reviseGoal(P);
                        g.start();
                        } else
                        evaluateGoal(G);
            }
```

Figure 15. Cognitively Modelled Agent-based Travel Planning Scenario Modelled according to COM-MAA



High-Level Architecture of Distributed Collaborative Multi-Agent Application

Travel Planning Scenario

The high-level architecture of the travel planning scenario developed to demonstrate the enhanced cognitive abilities of agents is shown in Figure 15) is a customised adaptation from the vision of travel planning agents presented by Hendler (1999).

The top level functional goals of the demonstration application are as follows: The Multi-Agent based application is aimed to use cognitively modelled agents to solve travel problems given by a user. The user can propose to the user Agent his desired travel, and it will obtain a complete plan that inclu des information about transport, lodging, etc. The agents will Extract, filter and store information automatically from the Semantic Web using other agents. The system aims to use the same information that the user could find if he wish planning the travel himself. Cognitive Sharing of different kinds of abilities is to be demonstrated to gain efficiency in the problem solving task. The agents are simulated to reuse each others capacities, behaviours and offer affordances to each other. Agents closely work according to the user's characteristics, and functions based on the ultimate goals obtained from the user profile and adapt their functional behaviour according to the learned user preferences.

Roles Defined for Agents

Table 4 shows the Roles and Responsibilities defined for Agents involved in Travel Planning Collaboration Scenario. The Collaborative scenario aims integrate the abilities of a set of heterogenous agents. The system is made by a set of agents that can communicate and cooperate among them to reach the problem solution. All the agents in the application use FIPA Based Agent Communication Language for standardization purposes.

Cognitive Profiles of Agents in TPA

The cognitive profile ontology is central to representing the knowledge for agents. The elements of the cognitive profile ontology serve to represent the shared knowledge base of agents through which agents' cognitive awareness will be enhanced. The cognitive profiles are designed to simulate an environment such that some agents are limited in certain capabilities, while others are equipped with them in a complementary manner to facilitate interoperability, resuse and adaptive collaboration based on enhanced cognitive awareness. The cognitive profiles of the agents in the prototype application are shown in Table 5.

Reuse Mechanisms Employed

The Behaviour API and Interaction Protocol API of JADE (Bellifemine et. Al, 2001; 1999; JADE 2004) are used to model the Agent's Actions, or an action Plan. ACL Messages are used as representations for Intentions and perception. An agent is simulated in such a way that it is given runtime capability to change its behaviour, and dynamically change profile so as to demonstrate the power and potential of the Ontological Model.

Cognitive Modelling of Agent Interactions and Communication Scenarios Through CogAC

Table 6 shows an example of how the agents collaboration is modelled through the CogAC.

Illustration of Improved Cognitive Awareness

The provision of cognitive profile as shared knowledge base serves as means to increase the cognitive awareness for agents since they can not only reason about their own cognitive distances, they can also access and query other agents' cog-

Table 4. Roles and Responsibilities defined for Agents involved in Travel Planning Collaboration Scenario

Agent	Functional Role of Agent in the Application
UserAgent	• This agent handles a user query and shows him the solution. To do so, it analyzes the problem and obtains an abstract representation. Subsequently it requests a Travel Planner Agent solutions to that problem. The User Agent has different skills like communication with Travel Planner Agents and users, or learning the user's profiles necessary to customize the system answer. The User Agent has a set of interfaces to allow input and output information and the user evaluation of the solutions found.
Travel Planner Agent	• The main Travel Planner Agent's goal is reason about User Agents and other Travel Planner Agents problems, and find out a set of possible solutions. Travel Planner Agents have different skills like communication (with different agents in the system), planning (its main reasoning module) and learning.
Transport Broker Agent	• This is a mediator agent, who has the ability of directly communicating with a transport agent and may provide services to some other agent which may not be able to directly communicate with a transport agent thus acting as an intermediary.
Transport Agent	• This agent has the capability of finding desired transport options from the web service providers and provides this information to other agents.
Translator Broker Agent	• This is a mediator agent, who has the ability of directly communicating with a translator agent and may provide services to some other agent which may not be able to directly communicate with a translator agent thus acting as an intermediary.
Translator Agent	• This agent simulates a functionally computational agent on the semantic web which has the capability of performing translation services upon request from one language to another e.g. English to Italian.
Currency Converter Agent	• The role of this agent is to retrieve up to date currency conversion rates from the web and provide currency conversion services to other agents upon request.
Airline Service Providers	•Airline Service Provider is responsible for finding information relation to airline reservations.
Accommodation Service Providers	• These are agents belonging to organization such as Hotels etc. which maintain up to date information about the accommodation availability, rates etc, and can carry out automated bookings on behalf of their owners.
Cognitive Broker Agent	• This agent also plays are central role in the collaboration scenario by acting as an indexer of facilitator for other agents to access other agent's cognitive profile.

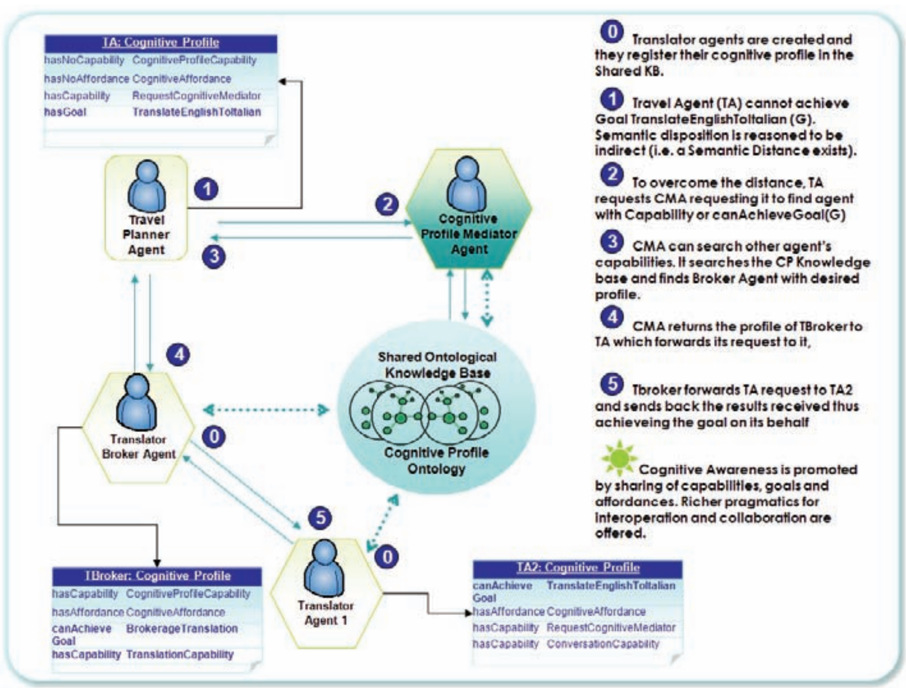
Figure 16. Agent Collaboration Scenario to Illustrate Improved Cognitive Awareness



nitive profiles allowing them to adaptively refine their interactions in attempt to achieve their goals in a collaborative manner. An illustration of how this proves so is shown in Figure 16.

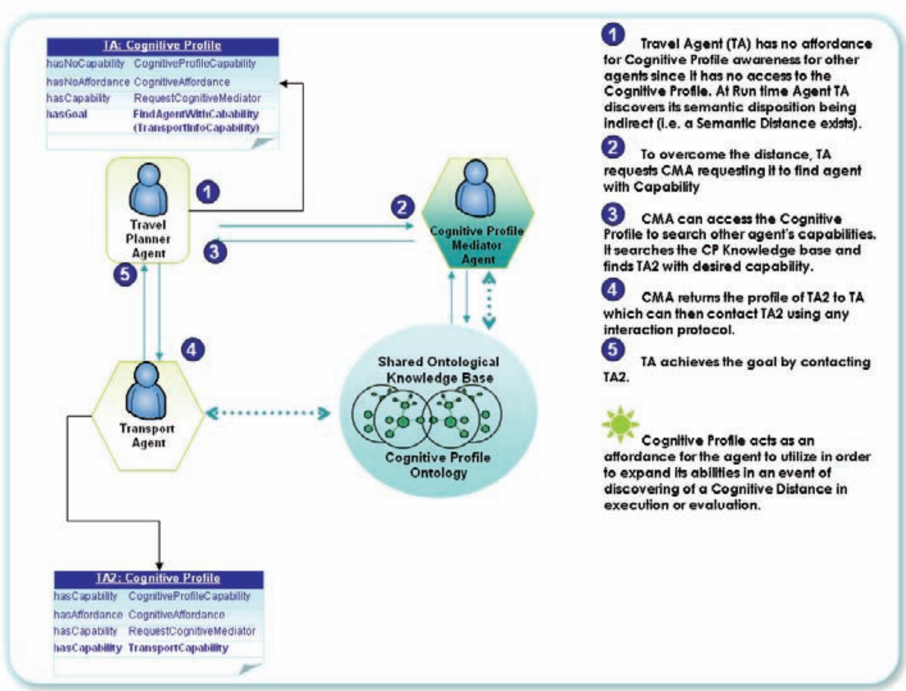
Cognitive Profile as an Affordance

The cognitive profile in the form of ontology serves as an affordance for the agent to be cognitively aware of its environment and make adaptive decisions about it. Following is a scenario in Figure 17 that illustrates how this proves so.

EVALUATION AND FUTURE TRENDS

The application of the COMMAA to the application was found very useful in structuring the agents' interaction and collaborations in an MAS environment. An attempt to assess the directness of engagement using the distances in the multi-agent interaction scenario offered useful results. As shown by the demonstration that the Cognitive Modelling of agents give a powerful boost and shows great potential in the manner that agent utilise each other's capabilities to support each other functional execution and in return facilitate and reduce cognitive overload of humans. The increased cognitive awareness promotes interoperation amongst agents and results in behaviour sharing and reuse. The high visibility into each other's mental models increases the mapping of agent's functional and execution models. The 7 stages of CogAC ensure that enough feedback is received to ensure successful fulfilment of goals through multi-agent collaboration. The Cognitive Profile Ontological Model serves as an essential artefact for agents which, continually

Figure 17. Multi-Agent Collaboration Scenario to illustrate the use of Cognitive Profile as an affordance



**Further implementation details are beyond the scope of this chapter* provides for both sides of the CogAC: execution and evaluation.

Based on the above evaluation of the application, The CogAC can come to be considered as a fundamental part of the functioning of agent's actions in interaction with its MAS environment. Thus agent modelled along lines of COMMAA exhibit strong principles of user-centred design and advocate ease of use, efficiency and reuse and interoperation. Although, the model is used to model software agents, similar model can be used for classifying user roles and capabilities and for maintaining and sharing user profiles and roles. The proof-of-concept application has also demonstrated the feasibility of implementing the constructs of COMMAA using the combination of Multi-Agent Platform and the Semantic Web middleware.

In addition, the COMMAA takes a holistic view of agent's action and its processing in the stages of execution and evaluation. It increases the cognitive awareness amongst agents by elabo-

Table 7. Improvements achieved as a result of application of COMMAA

Design Goals	Evaluation
Cognitive Awareness:	▪ Agents profile has shown to be encoded using OWL ontology and published. Thus Agents are able to cognitively describe, publish and access each others capabilities, affordances and distances/constraints by Quering the ontology using SPARQL based mechanism. More dynamic and adaptive behaviour of agents has been shown. Thus the implementation shows cognitively aware modelling agents interaction. ▪ Agents can carry out cognitively aware communication and collaboration with each other ▪ Through Cognitive awareness, agents help each other identify and bridge the gulfs of execution and evaluation
Enhanced Negotiation and Collaboration	▪ As shown by the collaboration scenarios, agents negotiation abilities are enhanced as a result of improved cognitive awareness
Flexibility and Reusability:	▪ As shown, through cognitive profiling, JADE Behaviour API and Interaction protocols have been used with much more flexibility and their reuse is promoted by agents sharing cognitively their goals and abilities. ▪ Agents are equipped with reasoning mechanism to dynamically reason about their semantic and articulatory disposition. This allows them to adapt to the required interaction scenario, thus providing intrinsic support for more flexible interaction.
Adaptive Interaction and Interoperability:	▪ Heterogenous agents in different roles including Transport Agents, Transport and Translator Brokers, Currency Convertors etc. have been shown to participate in adaptive collaborative scenarios through dynamic sharing of their cognitive profiles in order to help each other bridge cognitive distances of execution and evaluation. In doing so, they help each other achieve their goals. ▪ Interoperability is promoted through the sharing of cognitive profiles, dynamic publish and access mechanisms. ▪ Reasoning through SWRLJess based rules enhances cognitive awareness, thus improving interoperability.
Discovery based on Heuristic reasoning:	▪ Agents dynamically reason about their profiles using SWRL Rules and DIG reasoners that classify ontology. This allows dynamic discovery of cognitive distances and other agents' profiles improving agents cognitive awareness of itself and the environment.
Minimisation of cognitive load:	▪ User has been shown to be relieved of much cognitive overload since agent through all of the above functionalities is able to perform much more. It is able to meet all the preferences in the user profile. If the case was otherwise, the distribution of tasks would shift from the agent to the user. E.g. if the agent was unable to meet the goal of converting dollar to pound, given it was not able to find any other agent to achieve the goal, the user would have the added cognitive overload of meeting the desired goal on its own. ▪ Thus human information processing has shown to be reduced as a result of increased cognitive awareness and improvement in the flexibility and adaptability of agents' collaborative abilities.

rating the action infrastructure, its limitations, constraints (Distances) and its capabilities and affordances. In this way it facilitates the architecture for the agents that are designed to work or be programmed to work more adaptively on the Semantic Web. This was made sufficiently evident using the implementation of the Travel Planning scenario. Similarly, agents can use the semantic information, share it, yet can communicate using ACL languages, programmed according to the Agent principles and do not need to rely on the Web service interfaces and profiles.

The results of the application are validated against the design goals presented earlier in Table 7.

Future Directions

The abstract architecture opens new doors of research. With the core framework in place the natural next step in its expansion is the specialised enhancement towards a more rigorous definition of different levels and variations of cognitive profile and its parameters. Identifying the best level of detail for functionally decomposing each task or intention and applying it consistently is difficult. The application highlights that in order to make this model fully implementable or workable in the real world, there needs to be taxonomy of distances, directness measures, capabilities and affordances defined. This study initiates this activity by identifying the rudimentary picture of the basic Cognitive profile of agents e.g. at present the capabilities were identified as high level constructs. They can be made much more elaborate e.g. that of OWL-S. However to make it reach such a state of maturity where it could be utilised in practice will take some more effort. A taxonomy could be appealing because it would allow a generic to specific discussion of cognitive distances across different agent applications. Although some subset of cognitive distances will always be generic, it can be suspected that a fairly large subset will need to be specialised across limited applications.

Ontology Learning, Alignment and Mapping: A serious issue in making this model work on a larger scale will be ensuring the standardization for the interoperability. Issues of Ontology learning (Maedche & Staab 2001), Ontology alignment and mapping (as highlighted in works by Laera et al. 2006, Mocan, Cimpian & Kerrigan 2006; Sampson & Lanzenberger 2006) also become important for standardization and homogenization purposes. Standardization of cognitive profile for agents will be another issue foreseen if this model were to work successfully, but with rich semantic model of OWL and RDF will allow for standardization to be achieved. However it provides substantial stimulus for future research.

Enhanced Learning and Reasoning Mechanisms: Furthermore, an idea that will add immense value to the further development of agents' cognitive model is enhanced Reasoning and learning mechanisms. It would also be worth investigating how the principles of COMMAA plays a useful role in Interface characteristics i.e. investigation into role of cognitive models applied to model interface agents and their activities and management of user profiles. Another issue is with respect to the extent to which agent's knowledge model or cognitive profile is to be shared. The notion of Public, Private profile could be considered. The extent of autonomy given to the agent moving towards Autonomous Semantic Web services (Paolucci & Sycara 2003) is also highly relevant.

CONCLUSION

The Semantic Web community has recognised the advantages of an agent-based approach to building deployable solutions in a number of application domains comprising complex, distributed systems. The chapter targeted some of the key challenges faced when developing autonomic and autonomous entities in the domain of Multi-Agent Collaborations. By applying cognitive models to model agents' behaviour on the Semantic Web, a reasonably successful attempt has been made at coupling cognitive science principles of user-centred design with features of agent base systems and architectures.

This research took into account the emergent standards in both agents and Semantic Web in order to render the framework principles presented. The principles and design of COMMAA have also been used to demonstrate agents' improved capabilities through an evaluation of a multi-agent collaborative scenario to illustrate the adaptive coordination of different agents acting as owners in heterogenous and dynamically changing environments. The results of the evaluation show an improved flexibility, interoperability and reusability of agents' collective behaviours and goals. Thus, it establishes COMMAA as a step forward in providing the next generation of Semantic Web, a successful framework of multi-agent collaboration, which is inevitably required for generating robustly engineered agents able to carry out spontaneous and adaptive collaboration based on cognitive awareness of their environment and infrastructure.

KEY TERMS AND DEFINITIONS

Affordance: An affordance is a resource or support that the environment offers an agent for action, and that the agent can directly perceive and employ**.**

Agent: Agents are defined as autonomous, problem-solving computational entities capable of effective operation in dynamic and open environments.

Capability: The functional ability possessed by an agent to achieve some given goal or requirement.

Cognitive Awareness: It refers to the ability of the Web agents to diagnose their processing limitations and to establish interactions with the external environment (in the form of other agents including humans and software agents).

Cognitive Model: Internal representations of the current situation created by either a human and agent to assess their state with respect to the environment.

Cognitive Profile: It is a semantic representation model which includes information about the cognitive states of an agent, its functional capacities and affordances.

COMMAA (Cognitive Model of Multi-Agent Action): A framework for modeling agents' actions and interactions in its environment in an attempt to provide an architecture that improves the flexibility of Multi-agent interaction by promoting cognitive awareness .

Multi-Agent System: Multi-Agent System (MAS) is a distributed collaborative environment which allows a number of agents to cooperate and interact with other agents (including both people and software) that have possibly conflicting aims, in a complex environment.

Chapter 2.18
Utilisation of Case-Based Reasoning for Semantic Web Services Composition

Nottingham Trent University, UK

ABSTRACT

With the rapid proliferation of Web services as the medium of choice to securely publish application services beyond the firewall, the importance of accurate, yet flexible matchmaking of similar services gains importance both for the human user and for dynamic composition engines. In this article, we present a novel approach that utilizes the case based reasoning methodology for modelling dynamic Web service discovery and matchmaking, and investigate the use of case adaptation for service composition. Our framework considers Web services execution experiences in the decision making process and is highly adaptable to the service requester constraints. The framework also utilizes OWL semantic descriptions extensively for implementing both the components of the CBR engine and the matchmaking profile of the Web services.

INTRODUCTION

The Internet has become the market-place for a colossal variety of information, recreational and business services. Web services are increasingly becoming the implementation platform of choice to securely expose services beyond the firewall. Moreover, multiple Web services can be integrated either to provide a new, value-added service to the end-user or to facilitate co-operation between various business partners. This integration of Web services is called "Web services composition" and is feasible to achieve because of the Web services advantages of being platform, language neutral and loosely coupled.

Automatic Web service discovery and matchmaking is the principal aspect for dynamic services composition. The accuracy of the matchmaking (selection) process enhances the possibility of successful composition, eventually satisfying the user and application requirements. The current standard for Web service discovery, the Universal Description, Discovery and Integration (UDDI) registry is syntactical and has no scope for automatic discovery of Web services. Hence, current approaches attempting to automate the discovery and matchmaking process apply semantics to the service descriptions. These semantics are interpretable by the service (software) agents and should include WSDL-based functional parameters such as the Web services input-outputs (Martin et al., 2004a)(Akkiraju et al., 2005), and non-functional parameters such as domain-specific constraints and user preferences (Aggarwal, Verma, Miller, & Milnor, 2004).

The accuracy of automatic matchmaking of web services can be further improved by taking into account the adequacy of past matchmaking experiences for the requested task, which gives us valuable information about the services behaviour that is difficult to presume prior to service execution. Hence, there is a need for a methodology that uses domain-specific knowledge representation of the required task to capture the Web services execution experiences and utilise them in the matchmaking process. Case Based Reasoning (CBR) provides such methodology as its fundamental premise is that experience formed in solving a problem situation can be applied for other similar problem situation.

The article begins with describing the motivation behind the work. In the following section we review theory of Case Based Reasoning and describe how it can be utilised for modelling Web services matchmaking. Next we discuss the design of our matchmaking algorithm, its implementation highlights, and analyze preliminary results. Finally we investigate how case adaptation can further extend our matchmaking algorithm to cater for service composition and review related work.

MOTIVATION

The most practically deployed Web services composition techniques use the theory of business workflow-management as composition process model to achieve formalization for control and data flow. Mainly based on the Business Process Execution Language (BPEL) standard (Andrews et al., 2003), these techniques also have practical capabilities that fulfil the needs of the business environment, such as fault handling and state management. However, the main shortcoming of these techniques is the static selection and composition approach, where the service selection and flow management are done a priori and manually.

A popular research direction attempts to improve BPEL composition by introducing semantics to workflow-based composition (Osman, Thakker, & Al-Dabass, 2005). However, these approaches also match the static behaviour of Web services in terms of whether the service has similar description for functional and non-functional parameters. While for the candidate Web services it is highly likely that these parameters are semantically similar, it is the execution values for such functional and non-functional parameters that provide valuable guidance for the decision-making process regarding the service adequacy for the task. This is because service behaviour is difficult to presume prior to service execution and can only be formed based on the experience with the service execution.

Hence, the problem requires a methodology, which has the domain-specific knowledge representation system for capturing the Web services execution experiences and reason based on those experiences. We adopted CBR (Case Based Reasoning) as the engine for our Web services discovery mechanism because CBR's fundamental premise that situations recur with regularity (Aamodt & Plaza, 1994), i.e. experience involved in solving a problem situation can be applied or can be used as guide to solve other contextually similar problem situations. Reasoner based on CBR hence matches the previous experiences to inspire a solution for new problems.

OVERVIEW OF CASE BASED REASONING

The Case-Based Reasoning technology was developed in 1977 based on the research effort of Schank and Abelson. They proposed that our general knowledge about situations is recorded in the brain as scripts that allow us to set up expectations and perform inferences (Watson, 1997) The processes involved in CBR can be represented by a schematic cycle comprising four phases (Aamodt et al., 1994):

- RETRIEVE the most similar case(s);
- REUSE the case(s) to attempt to solve the problem;
- REVISE the proposed solution if necessary, and
- RETAIN the new solution as a part of a new case.

There are 4 main stages in CBR reasoning:

Case Representation

A case is a contextualised piece of knowledge representing an experience (Aamodt et al., 1994). It contains the problem, a description of the state of the world when the case occurred, and the solution to this problem. The solution contains elements that address the problem and inform about the relevance of the solution. When a reasoner is created, the elements of the case are defined according to the context. For example, the city of departure or the number of passengers could be some elements to represent a travel experience as a case. Case vocabularies are thus developed for each reasoner, to define what knowledge needs to be captured.

Case Storage and Indexing

Cases are then stored in a case library or case base. It is an important aspect for the designing of CBR systems because it reflects the conceptual view of what is represented in the case. The structure of the library should permit efficient search by the reasoner. This search can be facilitated by the use of indexing. Indices are therefore assigned to cases in order to express information about the case content.

Case Retrieval

Whenever a new problem needs to be solved, the case library is searched for the cases which can be a potential solution. The first phase of this search is case retrieval, which aims to find cases that are contextually similar to the new problem. The retrieval is done according to the index of the cases.

Matchmaking

Matchmaking performs the comparison between retrieved cases and the request to verify if a past solution can be reapplied. There are several available methods for matchmaking in CBR literature. The Nearest-Neighbour Matching and Ranking is an interesting one because it involves the assessment of similarity between stored cases and the input (request) case. It assigns importance ranking to properties of cases and then computes the degree of matching by comparing the cases for these properties (Kolodner & Simpson, 1989). The matchmaking process is thus performed on each retrieved case, and the most similar case to the input case is assigned the highest ranking. If the system finds a matching case, it is possible to reuse the solution suggested by the retrieved case for the new problem.

In our CBR matchmaking approach, Web services execution experiences are modelled as cases. The cases are the functional and non-functional domain specific Web services properties described using semantics. In this modelling, the case library will be the storage place for such execution experiences and is identical to Web service registry in that it stores Web services references, but unlike registries case libraries also describe execution behaviour.

Case retrieval is similar to Web services discovery problem in that both mechanisms seek to find potential Web services for the current problem. Case matchmaking is similar to Web services matchmaking as both attempts to select acceptable Web services, from the retrieved Web services during the case retrieval or Web service discovery phase respectively.

The apparent compatibility confirms our thesis that the CBR methodology is well suited to build automatic Web service composition frameworks

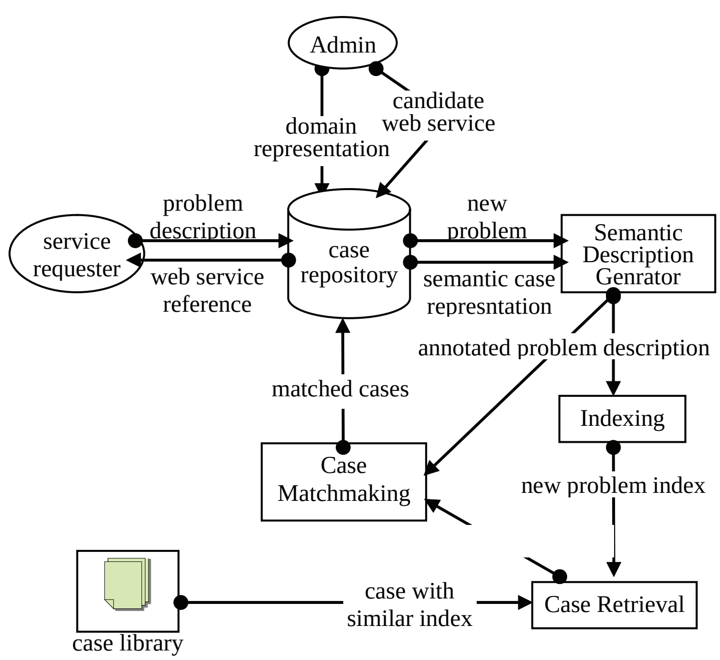
MATCHMAKING WEB SERVICES USING CASE BASED REASONING

The Framework Architecture

In our Semantic CBR matchmaking, there are two main roles: case administrator who is responsible for case library maintenance by entering or deleting cases from the library and case requestor who searches the case library to find solution for the problem. Figure 1 illustrates a schematic diagram for our framework.

The dynamics of the framework operation is as follows:

Figure 1. Architecture of the CBR matchmaking framework



- Initially, the administrator populates the repository with semantic case representation formats for specific application domain. This representation is used to semantically annotate both the user requests for suitable services and the execution experiences of Web services for the specific domain.
- The user inputs the service requirements and as a result receives Web service references via the framework interface. The same interface is used by service provides or the system administrator to subscribe a Web service as a candidate for available services for the specific domain.
- The case representation repository retrieves the appropriate semantic case representation format for the requested service and forwards it together with the problem description to the Semantic Description generator module, which semantically annotates the new problem according to the representation format.
- The annotated problem is then passed to the indexing module, which computes a suitable index for the new problem based on the domain feature and/or the functional parameters of the requested service. The index is passed for case retrieval.
- The case retrieval module queries the case library for cases with similar indexes. Output at this stage will be the cases that have similar index to the current problem, which will be candidates for matchmaking.
- The case matchmaking module takes the retrieved cases and the annotation of problem description from the semantic description generator module, runs them through a matchmaking algorithm and forwards the closest match Web service to the requester.

Although the chosen case study for this work is from the travel domain, the modular, ontology-driven design of framework makes it application-independent and allows for its seamless reuse for other applications domain. In order to enable matchmaking for the financial markets domain for instance, it would suffice to enter a new case representation format into the repository, keeping the rest of the reasoning logic intact.

Ontology Support for Case Representation and Storage

The most common use of ontologies is the reconciliation between syntactically different terms that are semantically equivalent. Applied to CBR case descriptions for Web services, ontologies can be used to provide a generic, reasoner-independent description of their functional and non-functional parameters. Moreover, ontologies can also be used to further index and structure cases with key domain features that increase the efficiency of the matchmaking process. For instance, we can add a feature to the travel domain ontology to indicate whether a trip is domestic or international. Web services QoS parameters are also indexed using ontologies to further improve the accuracy of case matchmaking.

In our framework, ontologies are also used to describe the rules of the CBR reasoning engine, which not only streamlines the intercommunication between the Web service, user request, and the case library, but promotes exploring the collaboration at the reasoning level between different composition frameworks.

Case Vocabulary

In CBR theory, the first step is to define all the elements contained in a case and the associated vocabulary that represents the knowledge associated with the context of a specific domain (our case study is the travel domain).

This vocabulary includes functional and non-functional parameters:

- Functional parameters are the service input (e.g. the travel details) and the service output or results (e.g. the travel itinerary). Input corresponds to the request of the user (e.g. date or city of departure) whereas output corresponds to the response given to the user (e.g. price, flight number).
- Non-functional parameters are constraints imposed by the user (e.g. exclusion of particular travel medium) or preferences over certain specific parameters (e.g. Price range, Quality of Service expected). In addition, execution experiences stored in the case library should also include the solution (i.e. Web services effectively used) and a notion to specify if the solution is acceptable for the end-user. Features that characterise the domain are extremely useful for top-level indexing and can also be included as non-functional parameters.

Case Representation Using Frame Structures

After deciding on the knowledge and corresponding vocabulary to be represented as a case, we need to decide how this knowledge can be represented.

In our approach, we adopt frame structures (Kolodner et al., 1989) the case representation. In frame structures, frame is the highest representation element consisting of slots and fillers. Slots have dimensions that represent lower level elements of the frame, while fillers are the value range the slot dimensions can draw from. In our implementation, slot dimensions represent case vocabulary in modular fashion while fillers describe the possible value ranges for the slot dimensions.

The frame representations are highly structured and modular which allows handling the complexity involved in representation. Moreover, frame structure has a natural mapping to the semantic OWL description language as the semantic net representations largely borrowed from the frame structures(Elaine & Kevin, 1992), which makes natural transition to the Semantic Web descriptions possible. Table 1 shows such a frame structure for our travel domain case vocabulary.

The slot Travel Request corresponds to the Input, i.e. all the travel details for a travel agent. The Travel Response slot corresponds to the Output, i.e. the answer given to the user at the end of the process. The elements of the answer are the price and the corresponding currency, the access point to the WSDL file of the corresponding Web Services and the Services Used (companies involved in the trip, e.g. an airline and a hotel).

Semantic Encoding of the Frame Structure

In the developed framework, we map the frame structures to ontologies. We derive rules for such mapping as described in Figure 2.

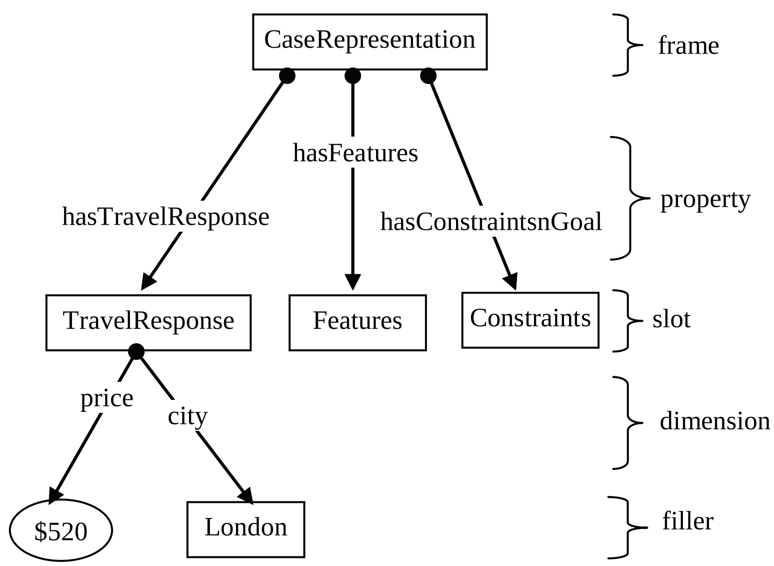
According to this mapping, frame and slot are represented as classes. The relationship between frame and slot is expressed in terms of properties of a frame, i.e. the range for these properties are the slot classes. Dimensions are the properties of the slots. Possible range for these properties is the values the respective filler can derive from.

We use Web Ontology Language (OWL), a Semantic Web standard for constructing these ontologies. OWL is the most expressive Semantic Web knowledge representation so far. The layered approach adopted by semantic web, allows reasoning and inference based on ontologies, which is the most powerful and ubiquitous feature of Semantic Web. After applying the mapping, the ontology for the travel domain case representation is created, where for instance the CaseRepresentation class has: hasTravelResponse, hasConstraintsOnGoal, and hasFeature object properties. Range for these properties are TravelResponse, Constraints, and Feature classes respectively.

Table 1. Representation of a case

Slot	Dimension	Filler
Travel Request	Name of Traveler	Any text
	Date of Arrival	Any valid date
	City of Departure	Any valid city
Travel Response	Solution	Service WSDL file
	Price Range	Any positive Double
	Currency	Any valid currency
Constraints	On Domain	Any Valid Travel Domain
	On Price range	Any positive Double
	On QoS parameter	Any possible QoS parameter(s)
Features	Travel Regions	Domestic/International

Figure 2. Mapping between frame structure and semantic case representation



globalization of semantic descriptions, we used external ontologies where appropriate. For instance, the property cityOfArrival is an object property referring to a publically available ontology(PORTAL, 2003) , where other useful information about the specific city can be found such as country, the number of inhabitants, etc.

An example of a semantically-encoded travel request is illustrated in Table 2. "Find a Trip for a single person, Mr Lee; Mr Lee wants to travel from Boston to New York, with a maximum price range in total of $220, He does not want to travel by road. The dates of Travel will be 27-02-2005 for departure and 01-03-2005 for return. He prefers to pay in USD and requires a fast response (approximately in 1.5 seconds)".

Case Storage

All the Web service execution experiences, i.e. solutions deemed valid for a particular request, are stored in the Case Library to be reused by

In order to exercise the noble objective of globalization of semantic descriptions, we used external ontologies where appropriate. For instance, the property cityOfArrival is an object property referring to a publically available ontology(PORTAL, 2003) , where other useful information about the specific city can be found such as country, the number of inhabitants, etc.

An example of a semantically-encoded travel request is illustrated in Table 2. “Find a Trip for a single person, Mr Lee; Mr Lee wants to travel from Boston to New York, with a maximum price range in total of $220, He does not want to travel by road. The dates of Travel will be 27-02-2005 for departure and 01-03-2005 for return. He prefers to pay in USD and requires a fast response (approximately in 1.5 seconds)”.

Case Storage

All the Web service execution experiences, i.e. solutions deemed valid for a particular request, are stored in the Case Library to be reused by the reasoner. The Case Library itself is also an ontology. It contains some instances of the class CaseRepresentation (e.g. a travel experience or a travel case).

DEVELOPMENT OF THE CBR MATCHMAKING FRAMEWORK

Case Indexing and Retrieval

To facilitate the search procedure, cases are indexed based on vocabularies. In our framework, we use “partitioning the case library” method, which is a variation of “flat memory indexing” technique (Kolodner et al., 1989). In this indexing method, case library is partitioned based on certain vocabularies and the new problem is recognized based on the identical vocabularies to decide which partition the problem falls into.

In our architecture, cases are stored based on vocabulary element Features as presented in Table 1, which corresponds to hasFeatures property from the CaseRepresentation ontology class. For our travel agent case study, the possible values for this property are either Domestic or International (predefined instances from the TravelRegion class), hence indexing will partition case library into two parts. In more complex examples more than one vocabulary term or a combination of terms can be used for more sophisticated indexing. As in relational databases selection, the efficiency of the retrieval process largely depends on the precision of the indexing.

Table 2. Example of a case

Name of passengers	Lee	<TravelRequest:namePassengers>Lee
City of Arrival	Boston	<TravelRequest:cityArrival rdf:resource= “http://localhost/uk/2005/City.owl#Boston”/>
Date of Arrival	1-3-05	<TravelRequest:dateArrival>2005-03-01
Constraint on domain	Road	<Constraints:OnDomain rdf:resource= “http://localhost/ntu/TravelDomain.owl#Airline”/>
Constraint on price	220	<Constraints:OnPrice>220
Constraint on currency	USD	<Constraints:OnCurrency rdf:resource= “http://ecs.soton.ac.uk/currency.daml#USD”/>
Constraint on QoS	1.5 s	<QoS:ExecutionDuration>1.5

Whenever a new Web service needs to be fetched, the problem description involving the functional parameters and non-functional parameters are encoded using the case representation frame structure, i.e. as an instance of CaseRepresentation ontology as illustrated in Table 2.

Matchmaking and Ranking

Case retrieval fetches Web services that are a potential solution to the problem. The matchmaking process narrows down the retrieved cases to present acceptable solution(s). From the available methods for matchmaking in CBR literature, we choose Nearest-Neighbour Matching and Ranking using numeric evaluation function (Remind, 1992) method for our framework. The method operates as follows:

- Compare the similarity for each property, between the new problem and the cases retrieved. The method used for comparison depends on the type of the property.
- Quantify the weight of the similarity. A ranking is assigned to each property in accordance with its importance as exemplified in Table 3.

For each case retrieved, the similarity degree is computed and the case with the highest score corresponds to the best-match. Similarity takes values between 0 and 1, which is attributed to each property for each retrieved case. Our similarity comparison method depends on the type of the dimension: data or object.

Data Property Comparison

To compare data type properties, like the price range or the value of QoS (e.g. execution time), we use the qualitative regions based measurement method (Kolodner et al., 1989). The closer the value in a retrieved case is to the value in the request, the higher the similarity coefficient is.

For each data type property, this formula used is: $|Vr - Vc| \leq X.[Vr|$, where V is the value of the property in the request r or in the retrieved case c and X the factor of tolerance. Thus, a factor of tolerance of 0.9 means the value of the retrieved case should be in ±10% region in relation to the value of the request. The optimum tolerance value is determined by the administrator and can be calculated heuristically.

Object Property Comparison

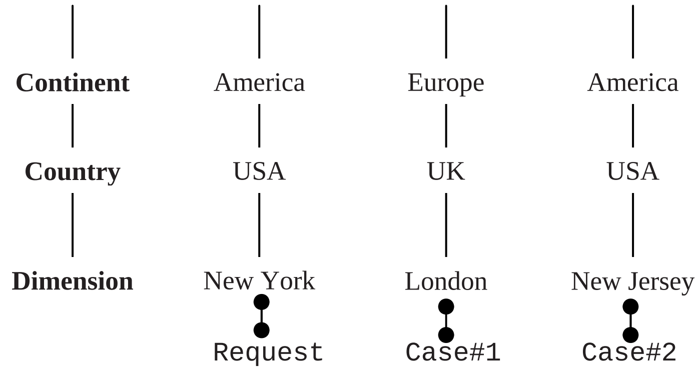
For the dimensions annotated as object properties, the possible filler values will be an instance of slot class. Hence, for semantically matching object property value of the new problem and the retrieved cases, the algorithm compares the instances. If the instances match, then the degree of match is 1. Otherwise, the algorithm traverses back to the super (upper) class that the instance is derived from and the comparison is performed at that level.

The comparison is similar to traversing a tree structure (Zhang, Arpinar, & Aleman-Meza, 2003), where the tree represents the class hierarchy for the ontology element. The procedure of traversing back to the upper class and matching

Table 3. Quantifying the travel domain case dimensions

Slot	Dimension	Importance (0-1)
Travel Request	City Departure	1.0
	City Arrival	1.0
Constraints on Goal	On Instance	0.2
	On Domain	0.8

Figure 3. Semantically matching object properties (dimensions)



instances is repeated until there are no super classes in the class hierarchy, i.e. the top node for the tree is reached, giving degree of match equal to 0. The degree of match (DoM) degree is calculated according to the following equation:

$$DoM = \frac{MN}{GN} \tag{1}$$

Where the MN is Total number of matching nodes in the selected traversal path, and GN Total number of nodes in the selected traversal path

For example, for the request in Figure 3, case#1 will return a degree of match of 0 because no matches are found while traversing the ontology tree until the leaf node is reached. However, for case#2, the degree of match will be 2/3=0.67 as the instances (New Jersey, New York) does not match but the instances of the Country super class match.

It is worth to note that Constraints on object properties are handled by omitting that path in the case ontology tree that renders the constraint invalid. For example, if the passenger is reluctant to travel by air, then the Brit Air, Flight path will not be traversed.

Computing The Overall Similarity Value

Overall similarity is evaluated by computing the aggregate degree of match (ADoM) (Remind, 1992) for each retrieved case according to the following equation:

$$ADoM = \frac{\sum_{i=1}^{n} W_i \times sim(f_i^N, f_i^R)}{\sum_{i=1}^{n} W_i} \tag{2}$$

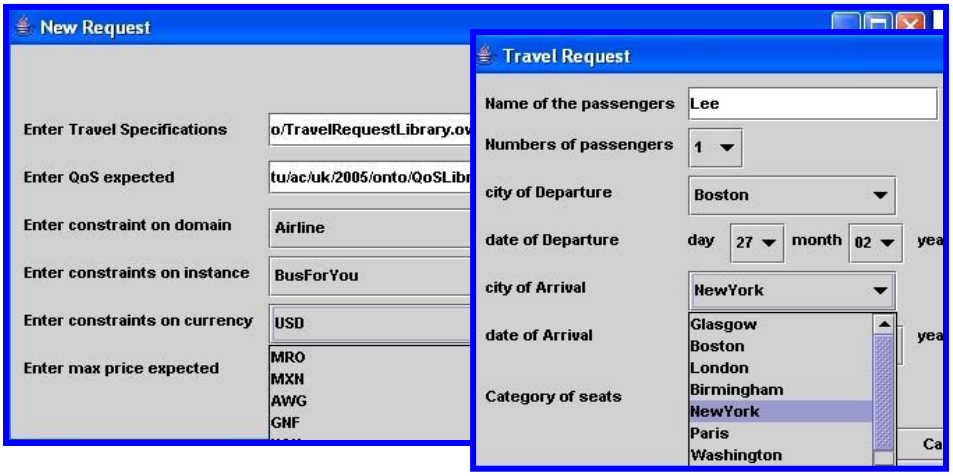
Where, n is the number of ranked dimensions, Wi is the importance of dimension i, sim is the similarity function for primitives, and fiN and fiR are the values for feature fi in the new problem and the retrieved case respectively.

The evaluation function sums the degree of match for all the dimensions computed in the previous step, and takes aggregate of this sum by considering the importance of dimensions.

IMPLEMENTATION HIGHLIGHTS

The implementation of our framework uses semantics extensively to implement both the utility ontologies describing the components of the Case-Based Reasoner (Case representation), and the domain ontologies that describe the profile of the Web services in the Case library with a semantic representation (Case Storage).

Figure 4. Admin and user interface



OWL was our ontology language of choice. We used Pellet (Parsia & Sirin, 2004) - a Java based OWL reasoner, as our ontology engine in favour of the more popular Jena (HP-JENA, 2003), because it supports user-defined simple types. Pellet was used to load and verify (type and cardinality) ontology class instances of user requests and candidate cases.

Figure 4 illustrates a snapshot of the GUI developed for the matchmaking framework. The interface allows different options to two kinds of users: The case administrator, who is responsible for maintaining the case library, and a standard client, who wants to retrieve Web services for a trip. The case administrator has admin privileges to perform case maintenance activities like case seeding, modifying the ranking system or deleting old cases. The client can also setup a ranking system, which will be applicable for a particular session.

While seeding the case library with a new case or making a new trip request, the interface assists the client in creating the required ontology instances. The value entered for a particular property is validated in relation to the range and cardinality drawn from the ontologies.

The solutions (cases) resulting from the matchmaking process are presented to the client are stored into the case library.

PRELIMINARY RESULTS

At this initial stage of development, the focus of our experiments was to validate the logic of our matchmaking framework, rather than testing a fully working prototype. Hence, we tested our framework with simple in-house developed Web services and compatible wrappers for external publicly available services.

In order to consolidate the test process, we applied different rankings against each test case and associated them with a specific profile. The profile represents a group of users that have similar requirements for the travel request. For instance, the Business profile stands for corporate users, who have to travel frequently; therefore a high standard of comfort is a significant element of choice. These users also need reliability of services. Price is not very important because firms very often have contracts with travel companies. On the other hand, for regular users, represented by the Personal profile, cost is of paramount importance.

The three other types of users are mainly based on specific comparison properties: Economic retrieves cases which price never exceeds a user-defined maximum amount; Travel Medium is specific for constraints on travel domain as well as instances; and Enterprise is useful for companies which are interested in using reliable services. The latter can be important if contracts between the company and different Web services exist so that they can restrict other services.

The rankings are currently administered centrally, but in the future we would like to give the users the opportunity to tweak some of them using a user-friendly interface. Table 4 shows the ranking of our profile system. Example of constraint on Domain is reluctance to travel using a certain transport and constraint on instance the exclusion of certain airline from the search. Quality of service is represented as a single parameter, but in this experiment it is expressed as the availability and response time of the service.

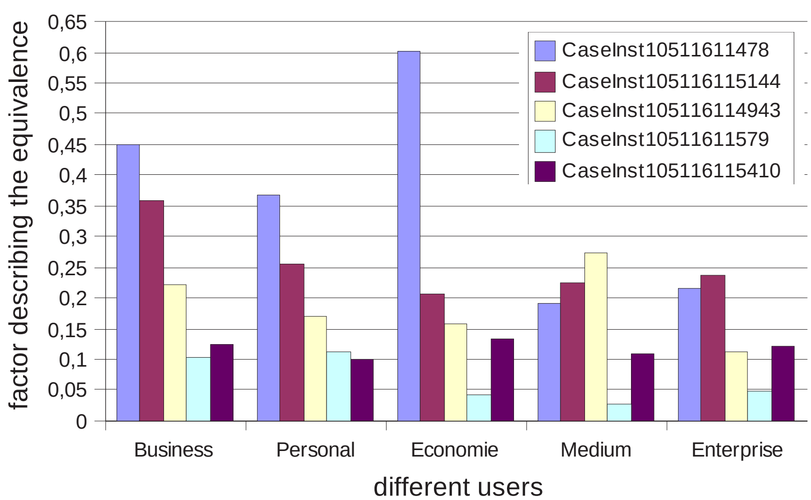
Figure 5 shows the matchmaking degree for different cases using the criteria above. Some cases (Web service execution experiences) present satisfactory results to all users (CaseInst10511611478). Another interesting highlight is that the chosen ranking systems provide different results only if the coefficients are significantly different. This is probably due to the fact that that our case library is not richly populated at the moment.

The average execution time of our matchmaking program at the time of the experiment was approximately 40 seconds, relatively slow considering we only have 30 cases stored in the library. Using semantics has the disadvantage of being more time-consuming than scanning databases. We identified the use of imported ontologies as the

Table 4. User profiles

	Property				
Profile	*Category*	*Constraint on Domain*	*Constraint. on Instance*	*Price*	*Quality of Service*
Business	0.6	0.6	0.4	0.1	0.5
Personal	0.2	0.4	0.7	0.5	0.2
Economic	0.2	0.4	0.2	1	0.1
Travel Medium	0.2	1	0.8	0.3	0.2
Enterprise	0.5	0.3	0.1	0.2	1

Figure 5. User profiles



main performance leak for our program. We plan to develop an off-line caching system to enable us to access the public ontologies locally.

EXTENDING THE MATCHMAKING FRAMEWORK TO WEB SERVICES COMPOSITION

The current framework addresses the problem of automatic Web services discovery and matchmaking by annotating Web services execution experiences and storing them into case base (Osman et al., 2006). The search considers domain-specific criteria and user preferences to find Web services execution experience that solved a similar problem in the past. However the framework assumes that the case library contains suitable cases for every possible problem. This assumption is not always satisfied considering the vast number of problems and problem parameters. Moreover, the framework also needs to deal with situations where the aggregate degree of match (ADoM) is below the *domain-specific* expected degree of match set by the domain administrator or to deal with negative user feedback, where the matched services are not acceptable to the user.

Work under progress involves exploring case adaptation, which is termed as the REVISE phase (Figure 6 - The REVISE phase in CBR) in CBR theory. Adaptation is applicable when the available cases cannot fulfil the problem requirements, so matchmaking is attempted by adapting available cases. Adaptation looks for prominent differences between the retrieved case and the current case and then applies formulae or rules that take those differences into account when suggesting a solution (Watson & Marir, 1994).

Applied to the current framework, when the existing web services experiences in their original form are not sufficient to satisfy current request, the framework should look for relaxing the case restrictions under which a solution is acceptable. If the latter fails, the framework should attempt to merge potential cases to suggest a *composite* solution.

Case adaptation can be defined by the following formula (Maher & Garza, 1997)

$$C' = \alpha(C) \tag{3}$$

Where, C' = new case, C = old case(s) and α indicates adaptation operator.

The adaptation operator indicates the process of identifying and substituting or transforming an existing solution to fit new situations and is used in *knowledge-based substitution* adaptation.

Knowledge Based Substitutions

In CBR matchmaking process previous cases cannot be always reused without making some changes. Reasoning about these changes requires general and domain specific knowledge to mould case adaptation. For example, if an existing case-solution is applicable for the current travelling problem with the exception of the travel medium

Figure 6. The REVISE phase in CBR

REVISE

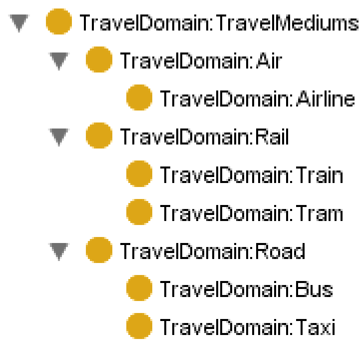
IF ADoM < $\{C_{results}, ADoM_{expected}\}$

OR

IF$\{C_{results}\} \neq U_{expected}$

$U_{expected} \rightarrow$ User expected results
$C_{results} \rightarrow$ proposed case solutions

Figure 7. Local search



– Bus (a road based travel medium which is constrained in the current problem), then the reasoner should use local search on knowledge structure (see the ontology in Figure 7) and conclude the Taxi domain as a possible substitution. Similarly, interpolating parameter of old solution to adapt for the new problem can solve the problem of parameter mismatch.

Another substitution method can use the semantic "sibling" rule for equivalent classes to enables them to replace each other in order to present an appropriate solution.

Under this circumstance, the Equation 3 can be reformulated as:

$$C' = \alpha(C, K) \qquad (4)$$

Where K indicates the influence of general or domain specific knowledge.

The role of knowledge in repairing the existing cases can be described as follows:

- Relaxing the service descriptions (functional parameters) to find a sufficiently similar description (applied at the description level).
- Relaxing the execution values of candidate cases (their non-functional parameters) in an attempt to adapt the solution.

The criteria for applying knowledge based substitution are:

- In a situation, where the reasoner cannot find an exact or reasonable match or where exact match is not possible or not desired or not required.
- To make absolutely sure that only possible solution is transformation, which is an expensive operation involving an AI planner, which is a resource expensive exercise.

Hence, if for the current problem C, the available cases in the case library are:

$$C_{libray} = \{\ C_1\ (S_1{+}S_2,\ F_1),\ C_2\ (S_2{+}S_3,\ F_2),\ C_3\ (S_1,F_3),\ C_4\ (S_2,F_4)\ ,\ C_5\ (S_1{+}S_2,\ F_5)\ \ \}$$

Where, C (S, F) indicates cases with Web services as solution S applied under circumstances defined by F The circumstances can be characterized by service description, problem description, constraints and preferences applied while solving the problem.

Then the solution for new problem C, C_6 (S_1 + S_2, F_6) must be reached by exploring the matching cases C_1 and C_5 first, before transforming C_3 and C_4 to find a solution from a scratch.

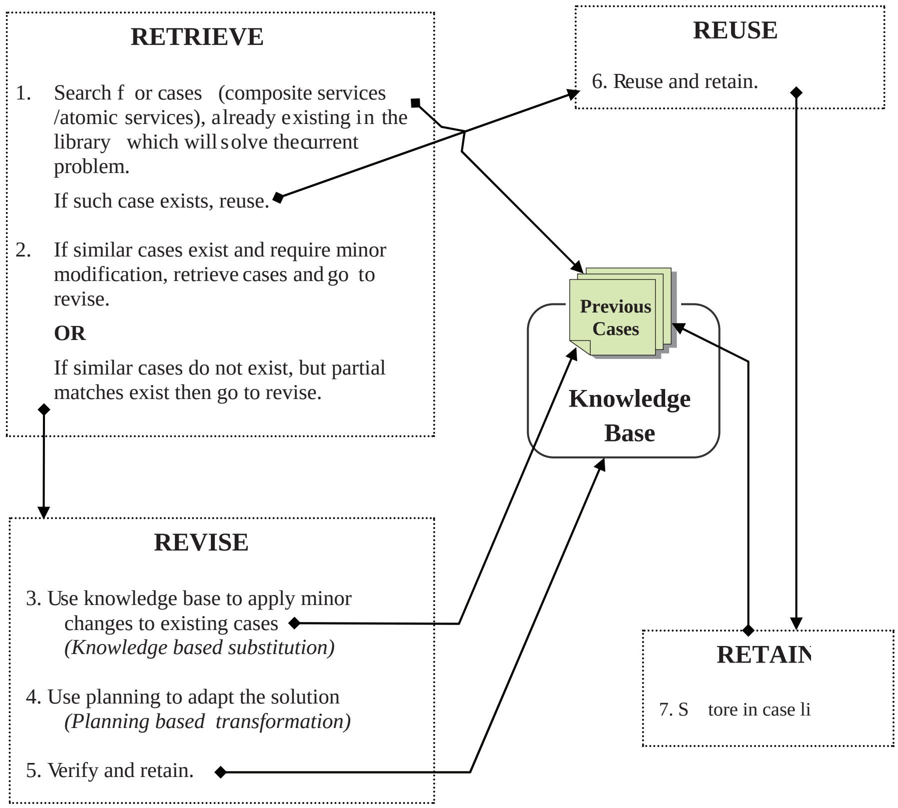
Planning Based Transformations

The planning based transformations can be applicable when the available solutions can not fulfil the problem requirements with normal matchmaking and discovery mechanism or by applying minor modifications using substitution based transformation. Under these circumstances, the equation 3 can be reformulated as:

$$C' = \alpha(C,\ \rho) \qquad (5)$$

ρ indicates the application of planner for transformation, where classical planner handles the task of coming up with a sequence of actions that will achieve a goal (Russell & Norvig, 2003). The planning phase is a resource-intensive and computational expensive (Selman, 2000; Long &

Figure 8. CBR methodology for Web services composition (modified from [(Aamodt et al., 1994)])



Fox, 2002) yet inevitable option, hence the two previous phases should narrow down the number of possible services planner can successfully use to generate a composed service.

Figure 8 on the shows the holistic CBR methodology to achieve Web services composition using the REVISE cycle.

RELATED WORK

Semantic descriptions are increasingly being used for exploring the automation features related to Web services discovery, matchmaking and composition. In (Zhang et al., 2003) such semantic-based approach is described. They use ontology to describe Web services templates and select Web services for composition by comparing the Web service output parameters with the input parameters of other available Web services. A constraint driven composition framework in (Aggarwal et al., 2004) also uses functional and data semantics with QoS specifications for selecting Web services. DARPA's OWL-S (Ontology Web Language for Web services) is the leading semantic composition research effort. OWL-S (Martin et al., 2004b; Ankolekar et al., 2001) ontologies provide a mechanism to describe the Web services functionality in machine-understandable form, making it possible to discover, and integrate Web services automatically. An OWL-based dynamic composition approach is described in (Sirin, Hendler, & Parisa, 2003), where semantic description of the services are used to find matching services to the user requirements at each step of composition, and the generated composition is then directly executable through the grounding of the services. Other Approaches use Artificial

Intelligence planning techniques to build a task list to achieve composition objectives: selection of services and flow management for performing composition of services to match user preferences. (Mcllraith & Son, 2002) uses Golog – AI planning Reasoner for automatic composition, while in a similar spirit some other approaches (Wu, Parisa, Hendler, Nau, & Sirin, 2006; Nau, Cao, & Lotem, 1999) have used the paradigm of Hierarchical Task Network (HTN) planning to perform automated Web service composition. These approaches use semantics for automatic Web services discovery, but they overlook the Web service execution behaviour in the decision-making process.

Use of CBR, Semantic Web and Web services are common technologies in our effort and the efforts in (Nern et al., 2006) with different objectives, their's being to consume these technologies to assist the procedure of Semantic Web services creation using Case-Based reasoning approach, while our main concern is services composition.. Their INFRAWEBS project has Semantic Web Unit (SWU) – a collaboration platform and interoperable middleware for ontology-based handling and maintaining of Semantic Web services. The framework provides knowledge about a specific domain and relies on ontologies to structure and exchange this knowledge to Semantic Web services development process.

There is also a number of existing approaches which applies CBR for workflow modelling. (Madhusudan, Zhao, & Marshall, 2004) proposes an approach to support workflow modelling and design by adapting workflow cases from a repository of process models where workflow schemas are represented as cases and are stored in case repositories. The cases are retrieved for a problem which requires similar business process to solve the problem. The description and implementation language of framework is based on XML and main focus is on assisting workflow designer in creating business process flows. In similar line, (Cardoso & Sheth, 2005) represents adaptive workflow management system based on CBR and targets highly adaptive systems that can react themselves to different business and organization settings. The adaptation is achieved through the CBR based exception handling, where the CBR system is used to derive an acceptable exception handler. The system has the ability to adapt itself over time, based on knowledge acquired about past execution experiences that will help solve new problems. Our approach concentrates on Web services as a unit of computation to take advantage of highly accessible and loosely coupled nature of Web services technologies. We focus on utilising service execution experiences to best serve user requirements and encode the framework with semantics.

Experience based learning using CBR is a relatively old branch of Artificial Intelligence and Cognitive Science and is being used (Hammond, 1986; Ashley & Rissland, 1988) as an alternative to rule-based expert system for the problem domains, which have knowledge captured in terms of experiences rather than rules. However, Case based reasoning for Web services was initially documented in (Limthanmaphon & Zhang, 2003), where the developed framework uses CBR for Web services composition. In their approach, the algorithm for Web services discovery and matchmaking is keyword based and has no notion for semantics. This affects the automation aspects for Web services search and later for composition. Similar approach described in (Diaz, Salgado, Moreno, & Ortiz, 2006) proposes an extension of UDDI model for web services discovery using category-exemplar type of CBR, where web services are categorized in domains and stored as exemplar (Porter & Bareiss, 1986) of particular domain. Their implementation of CBR reasoner facilitates UDDI registry by indexing the cases based on the functional characteristics of Web services. However, the approach does not take into consideration the importance of non-functional parameters in service selection and the use of semantics at CBR level is peripheral as they primarily use the UDDI based component for service discovery. UDDI is text-based leaving little scope for automation. Our framework consumes semantics extensively and achieves the automation required for Web service discovery and matchmaking. Use of ontologies also makes our framework extensible and reusable.

CONCLUSION

Semantic description of Web service profile paves the way for automating the discovery and matchmaking of services since it allows intelligent agents to reason about the service parameters and capabilities. However, the accuracy of such automatic search mechanism largely relies on how soundly formal methods working on such semantic descriptions consume them.

In this article, we argued for the importance of considering the execution values for semantically described functional and non-functional Web services parameters in decision making regarding Web service adequacy for the task. This is because the service behaviour is impossible to presume prior to execution and can only be generalized if such execution values are stored and reasoned for deciding service capability. AI planning and Intelligent Agent based reasoning methods offer rule-based reasoning methodology rather than experience-based. Hence, we used Case Based Reasoning method that allows capturing experiences and reasoning based on them.

We implemented a Semantic Case based Reasoner, which captures Web service execution experiences as cases and uses these cases for finding a solution for new problems. The implemented framework extensively uses ontologies, as semantics are used both for describing the problem parameters and for implementing components of the CBR system: representation, indexing, storage, matching and retrieval. Our approach for modelling CBR as ontology-based reasoner achieves developer transparency and makes the framework extensible and reusable.

A problem that research in semantic-based matchmaking and composition has not addressed sufficiently is the interoperation between independently developed reasoning engines. Without this interoperation, the reasoning engines remain imprisoned within their own framework, which is a drawback, especially that most engines usually specialise in servicing a particular domain, hence interoperation can facilitate inter-domain orchestration. We believe that in this work we took a small step towards standardization at the reasoner level by describing the CBR reasoning model semantically

In this article we also presented the preliminary experimental results of our framework, which informally proved the correctness of our approach despite the relatively slow response time of the matchmaking process. The latter is primarily attributed to exporting external ontologies, which can be countered by utilising off-line caching of public ontologies. The experimental results also demonstrated the advantages of classifying user groups into profiles that have standard set of constraint rankings.

The final contribution of the article was documenting our investigation into extending the discovery and matchmaking algorithm to cater for web services composition. We discuss how we envisage exploiting the REVISE stage of the CBR cycle, i.e. case adaptation, to facilitate service composition. The article advocates an exhaustive *knowledge-based substitution* approach to adapt the functional and non-functional attributes of the candidate case to the requested solution before suggesting more complex and computationally taxing AI-based planning-based transformations that integrate the service profile of a number of cases to deliver candidate solutions.

The next stage of this research will involve the formal validation and implementation of our adaptation-based composition model.

Chapter 2.19
Rule Markup Languages and Semantic Web Rule Languages

Adrian Paschke
Freie Universität Berlin, Germany

Harold Boley
National Research Council, Canada

ABSTRACT

Rule markup languages will be the vehicle for using rules on the Web and in other distributed systems. They allow publishing, deploying, executing and communicating rules in a network. They may also play the role of a lingua franca for exchanging rules between different systems and tools. In a narrow sense, a rule markup language is a concrete (XML-based) rule syntax for the Web. In a broader sense, it should have an abstract syntax as a common basis for defining various concrete languages addressing different consumers. The main purposes of a rule markup language are to permit the publication, interchange and reuse of rules. This chapter introduces important requirements and design issues for general Web rule languages to fulfill these tasks. Characteristics of several important general standardization or standards-proposing efforts for (XML-based) rule markup languages including W3C RIF, RuleML, R2ML, SWRL as well as (human-readable) Semantic Web rule languages such as TRIPLE, N3, Jena, and Prova are discussed with respect to these identified issues.

DOI: 10.4018/978-1-60566-402-6.ch001

INTRODUCTION AND MOTIVATION

Web rule languages provide the required expressiveness enabling machine-interpretation, automated processing and translation into other such Web languages, some of which also being the execution syntaxes of rule engines. One of these languages may act as a “lingua franca” to interchange rules and integrate with other markup languages, in particular with Web languages based on XML and with Semantic Web languages (e.g. W3C's RDF Schema, OWL and its new OWL 2 version) for ontologies serialized in RDF/XML or directly in XML. Web rule languages may also be used for publication purposes on the Web and for the serialization of external data sources, e.g. of native online XML databases or RDF stores. Recently, there have been several efforts aiming at rule interchange and building a general, practical, and deployable rule markup standard for the (Semantic) Web. These encompass several important general standardization or standards-proposing efforts including RuleML (www.ruleml.org), SWRL (www.w3.org/Submission/SWRL/), SWSL (http://www.w3.org/Submission/SWSF-SWSL/), R2ML (oxygen.informatik.tu-cottbus.de/rewerse-i1/?q=R2ML), RIF (www.w3.org/2005/rules/), and others such as XCL (http://www.altheim.com/specs/xcl/1.0/), designed as a concrete (serialization) syntax for ISO's Common Logic (CL) standard.

In this chapter, a system of general requirements and design choices for Web rule languages will be introduced and instantiations discussed in the context of the current prominent general Rule Markup Languages and Semantic Web rule languages. This chapter is intended to be of help to a wide audience. In particular, it is targeted to rule practitioners who want to serialize the declarative rules of their applications in a general rule markup language, and publish and interchange them on the Web. Rule practitioners will find here a discussion of general design criteria with examples from the current rule markup languages. These examples, together with a discussion of advantages and drawbacks, will offer guidance to readers when declaratively representing their own rule-based applications in a Web rule language. The structure of the rest of this chapter is as follows: Section 2 introduces current rule markup languages and rule interchange formats as well as Semantic Web rule languages. Section 3 comprises the main part of this chapter, discussing important design issues and characteristics of the introduced rule languages. Section 4 presents future research issues in Web rule language design. Section 5 concludes this chapter with a summary.

WEB RULE LANGUAGES

Rule markup (serialization) languages have been developed for the Web-based interchange of, e.g., privacy policies, business rules, and - as focused here - Semantic Web rules. Rules are central to knowledge representation for the Semantic Web (Boley, 2007), hence are increasingly considered as being side by side with ontologies, e.g. in W3C's layered Semantic Web architecture (2007 version shown in Figure 1).

Rule interchange in an open format is important for all higher Semantic Web layers, including a Web of Trust and, generally, a Pragmatic Web (Paschke et al, 2007), and is crucial for applications in eBusiness, eGovernment, eHealth, etc. This section introduces major *rule markup languages* including RuleML, R2ML, and RIF, as well as human-readable *Semantic Web rule languages* such as TRIPLE and N3, and platform-specific rule engine languages such as Jena and Prova.

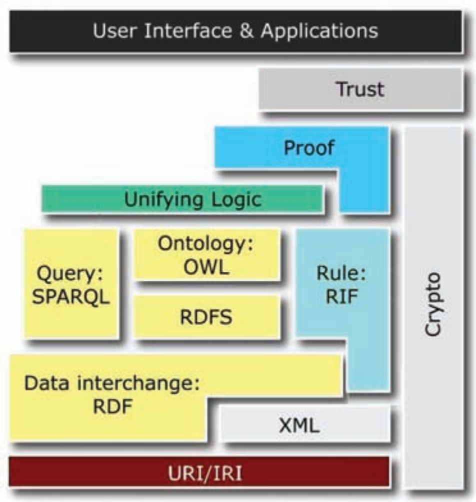
Rule Markup Languages

We characterize rule languages as rule markup languages if they are serialized in XML, employ URIs/IRIs for constants etc., and can interface with Web ontology languages.

RuleML

The Rule Markup Language (RuleML, www.ruleml.org) is a markup language developed to express a family of Web rules in XML for deduction, rewriting, and reaction, as well as further inferential, transformational, and behavioral tasks. It is defined by the Rule Markup Initiative (www.ruleml.org), an open network of individuals and

Figure 1. Semantic Web Layer Cake [adapted from (W3C, 2007)]



groups from both industry and academia that was formed to develop a canonical Web language for rules using XML markup and transformations from and to other rule standards/systems. It develops a modular, hierarchical specification for different types of rules comprising facts, queries, derivation rules, integrity constraints (consistency-maintenance rules), production rules, and reaction rules (Reaction RuleML, http://ibis.in.tum.de/research/ReactionRuleML), as well as tools and transformations from and to other rule standards/systems.

Datalog RuleML is defined over both data constants and individual constants with an optional attribute for IRI (URI) webizing . Atomic formulas have n arguments, which can be positional terms or, in Object-Oriented Datalog, slots (F-logic-like key->term pairs); OO Datalog also adds optional types and RDF-like oids/anchors, via IRIs (Boley, 2003). Inheriting all of these Datalog features, Hornlog RuleML adds positional or slotted functional expressions as terms. In Hornlog with equality, such uninterpreted (constructor-like) functions are complemented by interpreted (equation-defined) functions. This derivation rule branch is extended upward towards First Order Logic, has subbranches with Negation-As-Failure, strong-Negation, or combined languages, and is parameterized by 'pluggable' built-ins.

SWRL

The Semantic Web Rule Language (SWRL, www.w3.org/Submission/SWRL/) is defined as a language combining sublanguages of the OWL Web Ontology Language (OWL DL and Lite) with those of the Rule Markup Language (Unary/Binary Datalog).

The specification was submitted to W3C in May 2004 by the National Research Council of Canada, Network Inference (since acquired by webMethods), and Stanford University in association with the Joint US/EU ad hoc Agent Markup Language Committee.

Compared to Description Logic Programs (DLP), a slightly earlier proposal for integrating description logic and Horn rule formalisms by an overlapping authoring team, SWRL takes the opposite integration approach: DLP can be seen as the 'intersection' of description logic and Horn logic; SWRL, as roughly their 'union'. For DLP, the resulting rather inexpressive language corresponds to a peculiar looking description logic imitating special rules. It is hard to see the DLP restrictions, which stem from Lloyd-Topor transformations, being either natural or satisfying. On the other hand, SWRL retains the full power of OWL DL, but adds rules at the price of undecidability and a lack of complete implementations, although the SWRL Tab of Protégé has become quite popular (http://protege.cim3.net/cgi-bin/wiki.pl?SWRLTab).

Rules in SWRL are of the form of an implication between an antecedent (body) conjunction and a consequent (head) conjunction, where description logic expressions can occur on both sides. The intended interpretation is as in classical first-order logic: whenever the conditions specified in the antecedent hold, then the conditions specified in the consequent must also hold.

R2ML

R2ML (http://oxygen.informatik.tu-cottbus.de/rewerse-i1/?q=R2ML) was developed as a subproject in the EU Network of Excellence REWERSE (http://oxygen.informatik.tu-cottbus.de/rewerse-i1/). The R2ML project is about the design of integrity and derivation rules on the basis of the Rule Markup Language (RuleML) and the Semantic Web Rule Language (SWRL). R2ML defines a general markup framework for integrity rules, derivation rules, production rules and reaction rules. Rule concepts are defined with the help of MOF/UML, a subset of the UML class modeling language proposed by the Object Management Group (OMG) for the purpose of 'meta-modeling', i.e. for defining languages conceptually on the level of an abstract (semi-visual) syntax. From these MOF/UML language models concrete markup syntax is obtained by applying a mapping procedure for generating corresponding languages from parameterized schemas.

W3C RIF

The W3C Rule Interchange Format (RIF) Working Group (http://www.w3.org/2005/rules/wiki/RIF_Working_Group) is an effort, influenced by RuleML, to define a standard *Rule Interchange Format* for facilitating the exchange of rule sets among different systems and to facilitate the development of intelligent rule-based application for the Semantic Web. For these purposes, *RIF Use Cases and Requirements* (RIF-UCR) have been developed. The RIF architecture is conceived as a family of languages, called *dialects*. A *RIF dialect* is a rule-based language with an XML syntax and a well-defined semantics.

So far, the RIF working group has defined the *Basic Logic Dialect* (RIF-BLD), which semantically corresponds to a Horn rule language with equality. RIF-BLD has a number of syntactic extensions with respect to 'regular' Horn rules, including F-logic-like frames, and a standard system of built-ins drawn from *Datatypes and Built-Ins* (RIF-DTB). The connection to other W3C Semantic Web languages is established via *RDF* and *OWL Compatibility* (RIF-SWC). Moreover, RIF-BLD is a general Web language in that it supports the use of IRIs (Internationalized Resource Identifiers) and XML Schema data types. The RIF Working Group has also defined the *Framework for Logic Dialects* (RIF-FLD), of which RIF-BLD was shown to be the first instantiation. RIF-FLD uses a uniform notion of terms for both expressions and atoms in a Hilog-like manner.

Current efforts of the RIF Working Group are expected to introduce a *Core* (RIF-Core) in the intersection of RIF-BLD and a new *Production Rule Dialect* (RIF-PRD) influenced by OMG's PRR, which can then be further extended or supplemented by reaction rules.

Semantic Web Rule Languages

In contrast to the XML-based rule markup languages in the previous section, the Semantic Web rule languages described in this section are human-readable rule languages, using an ASCII syntax based, e.g., on the ISO Prolog syntax standard. Typically, they are designed as compact presentation languages for human consumption. While they may be serialized in an XML-based rule markup language such as RuleML or RIF, e.g. for interchange purposes, they can also be employed directly: dynamically interpreted by platform-specific rule engines (at runtime) or statically translated into executable code (at compile time).

TRIPLE

TRIPLE (http://triple.semanticweb.org/) was designed as a practical rule language for linked-data applications. It is an RDF query, inference, and transformation language for the Semantic Web extending F-logic with modules. TRIPLE rules have been used to implement RDFS and other schema languages.

N3 / Turtle

Notation3 (w3.org/TeamSubmission/n3/), more commonly known as N3, is a shorthand non-XML serialization of Resource Description Framework (RDF) models, designed with human readability in mind: N3 is much more compact and readable than RDF/XML serializations. N3 has several features that go beyond the serialization of RDF models, such as support for RDF-based rules. Supporting the triple pattern syntax of SPARQL, Turtle (w3.org/TeamSubmission/turtle/) is a simplified, RDF-only subset of N3.

Jena Rules

The default representation format in Jena (jena.sourceforge.net/) for a rule in the rule-based reasoner is a Java Rule object with a list of body terms (premises), a list of head terms (conclusions) and an optional name and an optional direction. However, in Jena2 a rather simple parser is included which allows rules to be specified in reasonably compact form in text source files.

Prova

Prova (http://www.prova.ws/) is both a (Semantic) Web rule language and a highly expressive distributed (Semantic) Web rule engine which supports complex reaction rule-based workflows, rule-based complex event processing, distributed inference services, rule interchange, rule-based decision logic, dynamic access to external data sources, Web Services, and Java APIs. Prova follows the spirit and design principles of the W3C Semantic Web initiative and combines declarative rules, ontologies and inference with dynamic object-oriented programming and access to external data sources via query languages such as SQL, SPARQL, and XQuery. One of the key advantages of Prova is its separation of logic, data access, and computation as well as its tight integration of Java, Semantic Web technologies and enterprise service-oriented computing and complex event processing technologies.

DESIGN AND CHARACTERISTICS OF WEB RULE LANGUAGES

General requirements that need to be addressed by a rule markup language include semantic expressiveness and clarity, computational efficiency and Web scalability, machine-readable and machine-interpretable syntaxes, usability by both human users and automated agents, compact representation, interchangeability with other formats, means for serialization and persistence, as well as tool support in authoring, parsing/generating, and verifying rules. An important property that refers to development-time software engineering quality is the extensibility of the language and its interoperability with other representation formats. In this section, general language design principles, together with a selection of four important issues and criteria for rule markup language design, are identified and characteristics of the current rule markup languages RIF, RuleML, R2ML, SWRL (DAML Rules) as well as specific Semantic Web rule languages are exemplified with respect to them. Further design issues and requirements for Web rule languages have been elaborated in, e.g., (Wagner et al, 2005), (Bry and Marchiori, 2005), (Boley, 2007), and (Paschke, 2007).

Language Design Principles

Given the large design space of rule languages and rule concepts, the specification of a rule markup language is a difficult integration and conceptualization challenge that calls for balancing many (interrelated) design choices with respect to semantics, syntax, and pragmatics. In this subsection, we will raise four (markup) language design principles and will illustrate the actual design choices of the current rule markup languages with examples.

1. Criteria of Good Language Design

Rule markup language should be clear, compact, precise and easily adaptable. They should strive to fulfill typical criteria for good language design (Codd, 1971) - as known from logic, databases and programming - such as minimality, referential transparency and orthogonality:

- *Minimality* requires that the language provides only a small set of needed language constructs, i.e., the same meaning cannot be expressed by different language constructs
- *Referential transparency* is fulfilled if the same language construct always expresses the same semantics regardless of the context in which it is used
- *Orthogonality* asks for pairwise independent language constructs, thus permitting their meaningful systematic combination

The RuleML family follows these design principles as far as possible and provides only a set of needed language constructs which can be applied in every meaningful combination. This leads to a compact homogeneous syntax which is easier to maintain, learn, read and understand by end users, as well as easy to process automatically by machines (e.g. translators).

SWRL and RIF, which build on RuleML, basically follow this compact minimalistic design approach. However, SWRL introduces a more fine-grained distinction of constructs than RuleML, e.g. of Atoms into various types of specialized atoms such as *classAtom*, *datarangeAtom*, and *invidiualPropertyAtom*, which can be formed from unary predicates (classes), binary predicates (properties), and equalities or inequalities.

R2ML introduces further differentiated types of terms and atoms. This leads to a rich structure-preserving syntax with many highly specialized constructs. For instance, variables in R2ML are provided in the form of *ObjectVariable* (i.e. variables that stand for objects), *DataVariable* (i.e. variables that stand for data literals), and *GenericVariable* (i.e. variables that do not have a type), whereas RuleML (as well as SWRL and RIF) only provide a generic Var construct. Like RuleML, R2ML defines the notion of an individual (constant) and distinguishes between objects and data with the notions of an *object name* and *data value*.

The main design goal of the specific Semantic Web rule languages such as TRIPLE, Jena, and (following ISO Prolog syntax) Prova is to provide a terse scripting syntax with a minimal set of needed constructs. RuleML's POSL syntax combines and extends the terse ISO Prolog and F-logic syntaxes.

2. Different Syntactic and Semantic Layers

A complete specification of Web rule languages consists of a formalization of their syntax, semantics and, often left implicit, pragmatics. As implied by their name, the syntax of markup languages always includes the concrete syntax of (XML) markup, perhaps indirectly through other languages such as via RDF/XML. Often, there is another more or less concrete syntax such as a compact shorthand or presentation syntax, which may be parsed into the XML markup. While a presentation syntax can already disregard certain details, an abstract syntax systematically replaces character sequences with abstract constructors, often in a (UML) diagram form or as an abstract syntax tree (AST). Together with different token dictionaries, it can be used to generate corresponding concrete syntaxes. The semantics is formalized in a model-theoretic, proof-theoretic, or procedural manner, sometimes in more than one. When rules and speech-act-like performatives, such as queries and answers, are transmitted between different systems, their pragmatic interpretation, including their pragmatic context, becomes relevant, e.g. in order to explain the effects of performatives - such as the assertion or retraction of facts - on the internal knowledge base (Paschke et al, 2007).

A general distinction of three modeling layers can be adopted from OMG's model driven architecture (MDA) engineering approach (http://www.omg.org/mda/):

- A platform specific model (PSM) which encodes the rule statements in the language of a specific execution environment
- A platform independent model (PIM) which represents the rules in a common (standardized) interchange format, a rule markup language
- A computational independent model (CIM) with rules represented in a natural or visual language

The *CIM level* comprises visual and verbal rendering and rule modeling, e.g. via graphical representation or a controlled natural language syntax for rules, mainly intended for human consumption. Graphical representations such as UML diagrams or template-driven/controlled languages can also be used as presentation languages.

In order to facilitate rule modeling, R2ML provides a UML-based Rule Modeling Language (URML) (Lukichev and Wagner, 2006) which allows visual rule modeling based on UML class models and OCL constraints. RuleML on the CIM level provides several tools that use a controlled natural rule language approach. Among them are TRANSLATOR (Hirtle, 2006), which is based on Attempto Controlled English (ACE) (Fuchs et al, 2006), the open source Reaction RuleML editor (http://ibis.in.tum.de/research/ReactionRuleML/index.htm#editor), which uses a template driven approach, and the commercial RuleManager (Ensig, 2007). The Protégé tool (http://protege.stanford.edu/) provides facilities for modeling SWRL rules, but only on the PIM level, i.e. rules are directly written in the concrete SWRL XML syntax. RIF, being a rather new standard under development, currently does not provide any such tool support.

The *PIM level* should enable platform-independent machine interpretation, processing, interchange and translation into multiple PSM execution syntaxes of concrete rule engines. Hence, the concrete XML (or RDF/XML-based) syntax of a Web rule language such as RuleML, SWRL or R2ML resides on this level, whereas the abstract syntax is on the borderline between the PIM and CIM levels. The abstract syntax can be defined, e.g., with the help of a suitably general grammar definition language such as the EBNF formalism, used, e.g., in the definition of the abstract syntax of OWL, RuleML, RIF, and SWRL, or with the help of a MOF/UML model, as, e.g., in PRR, R2ML, and RuleML. (Wagner et al, 2004) (Giurca and Wagner, 2005).

The *PSM level* is the result of translating/mapping PIM rule (interchange) languages into execution syntaxes which can be directly used in a specific execution environment such as a rule engine. A general distinction can be made between a compiled language approach, where the rules are statically translated into byte code (at compile time), as e.g. done in the rule engines Take (http://code.google.com/p/take/) and Drools (www.jboss.org/drools/) versus interpreted scripting languages, which are dynamically interpreted (at run-time), as e.g. in the rule engines Prova (Paschke, 2006b) and OO jDREW (Ball et al., 2005). While the compiled approach has obvious efficiency benefits, the interpreted approach is more dynamic and facilitates, e.g., updates at run-time. Often, Semantic Web Rule Languages are directly executable by their respective rule engines; hence reside on the PSM level. As an intermediate step between the concrete PSM level and the PIM level an abstract representation is often introduced, such as N3, which provides an abstract rule syntax based on the RDF syntax, or POSL and Prova, which both provide ANTLR grammars (http://www.jdrew.org/oojdrew/demo/translator, http://www.prova.ws/gram.html) which are transformed into ASTs as the basis for further translation into interchange markup languages such as RuleML or other, specific execution formats.

The correct execution of an interchanged PIM-level rule set serialized in a rule markup language depends on the semantics of both the rule program and the platform-specific rule inference engine (IE). To address this issue, the IE and the interchanged rule set must reveal their intended/implemented semantics. This may be solved via explicit annotations based on a common vocabulary, e.g. an (Semantic Web) ontology which classifies the semantics. Annotations describing the semantics of an interchanged rule set could even be used to find appropriate IEs on the Web to correctly and efficiently interpret and execute the rule program; for example, (1) by configuring the rule engine for a particular semantics in case it supports different ones, (2) by executing an applicable variant of several interchanged semantic alternatives of the rule program, or (3) by automatic transformation approaches which transform the interchanged rule program into a rule program with an applicable semantics; cf. XTAN (http://www.w3.org/2008/02/xtan/). Another approach is to specify additional meta test cases for testing typical properties of well-known semantics, where by the combination of succeeded and failed meta tests the unknown semantics of an IE can often be uniquely determined (Paschke, 2006).

We remark that, traditionally, rule-based systems have been supported by two types of inferencing algorithms: forward-chaining and backward-chaining. A general rule markup language, as a lingua franca, should support translation and interpretation of both reasoning directions, perhaps again using pragmatic annotations (where by default chaining should be bidirectional, as with the direction attribute in RuleML).

Independently from the semantics of an interchanged rule program, the pragmatic context in which the interchange takes place is important for the target environment, in order to know how the received information should be used and which actions should be taken with respect to the pragmatic aspects. A standard nomenclature of pragmatic performatives is defined by the Knowledge Query and Manipulation Language (KQML) (www.cs.umbc.edu/kqml/) and the FIPA Agent Communication Language (ACL) (FIPA, 2000), which define several speech-act-theory-based communicative acts.

3. Modular Specialized Schema Layers vs. Flat General Schema

There are two basic design principles for the concrete rule markup syntax. The language (or language family) may be implemented in one flat (monolithic) general XML schema or in a layered structure, where semantically related constructs are defined within separate modules that are added to the different language layers of the Web rule language (cf. http://www.ruleml.org/modularization/) . This leads to a hierarchical structure where higher language layers build on sublayers and add more expressiveness by extending them. The layers are not necessarily organized around expressiveness/efficiency to the language core.

R2ML follows the first approach and provides one quite large, flat XML schema for all different rule types and language constructs. In contrast, RuleML (also SWRL and RIF) follow the layered design principle and define new constructs within separate modules which are added to the respective layers in the RuleML language family. The layered and uniform design makes it easier to learn the language and to understand the relationship between the different features, and it provides a certain guidance to users who might be interested only in a particular subset of the features and who do not need support for the full expressiveness of the language. The modularization allows for easy extension of the language's representation capabilities, using the extensibility of XML Schema (e.g. a redefine of an XML Schema group definition), without breaking the core language standard. This development path provides a stable, useful, and implementable language design for rule developers to manage the rapid pace of change on the Semantic Web and modern rule systems. Apart from that, modules facilitate the practical and extensible development of a rule language family by bundling language constructs into layers which can be developed, compiled, tested and managed separately. The modularization also enforces the principle of information hiding and can provide a basis for data abstraction. However, a monolithic schema is easier to read by humans than an unevenly modularized one and, by now, some of the extant XML processing tools and editors do not fully support modular XML Schema definitions. This calls for flattening a layered schema on demand via automatic modular-to-monolithic translators, thus combining the advantages of modular development and maintenance with the advantages of monolithic delivery (for some validators and (object model) transformers, e.g. based on JAXB https://jaxb.dev.java.net/).

4. XML Elements vs. Attributes

A general question regarding the implementation of a concrete rule markup language is where to use XML elements and where attributes to define the rule constructs and the rule information content. A general discussion on this element-vs.-attribute issue can be found in the OASIS Cover pages (http://xml.coverpages.org/elementsAndAttrs.html):

- If the information in question could be itself marked up with elements, put it in an element.
- If the information is suitable for attribute form, but could end up as multiple attributes of the same name on the same element, use child elements instead.
- If the information is required to be in a standard DTD-like attribute type such as ID, IDREF, or ENTITY, use an attribute.
- If the information should not be normalized for white space, use elements. (XML processors normalize attributes in ways that can change the raw text of the attribute value.) (cf. http://www.ibm.com/developerworks/xml/library/x-eleatt.html)

Accordingly, RuleML's general markup conventions provide common principles for its language hierarchy. XML elements are used for representing language constructs as trees while XML attributes are used for distinguishing variations of a given element and, as in RDF, for webizing. Variation can thus be achieved by different attribute values rather than requiring different elements. Since the same attribute can occur in different elements, an orthogonal, two-dimensional classification ensues, which has the potential of quadratic tag reduction.

For example, recent work in RuleML led to orthogonal dimensions extending the RuleML 0.9 role tags for argument, <arg . . .>, and slots, <slot>. So far, the *unkeyed* <arg index="..."> was always *ordered*, as indicated by the index attribute, and the *keyed* <slot> was always *unordered*, as indicated by the lack of an index attribute. This was generalized by allowing an optional index attribute for both role tags, as shown by the independent distinctions in the following key-order matrix:

```
ordered unordered
keyed <slot index=”...”> <slot>
unkeyed <arg index=”...”> <arg>
```

Two extra orthogonal combinations are obtained from this system. First, *keyed*, *ordered* children permit positionalized slots, as in this cost fact (see Figure 2).

Here, slot names item, price, and taxes are provided, e.g. for readability, as well as index

Figure 2.

```
<Atom>
  <Rel>cost</Rel>
  <slot index="1"><Ind>item</Ind><Ind>jewel</Ind></slot>
  <slot index="2"><Ind>price</Ind><Data>6000</Data></slot>
  <slot index="3"><Ind>taxes</Ind><Data>2000</Data></slot>
</Atom>
```

positions 1-3, e.g. for efficiency.

Second, *unkeyed*, *unordered* children permit elements acting like those in a bag (finite multiset), as in this transport fact:

```
<Atom>
<Rel>transport</Rel>
<arg><Ind>chair</Ind></arg>
<arg><Ind>chair</Ind></arg>
<arg><Ind>table</Ind></arg>
</Atom>
```

Here, the arguments are specified to be commutative and 'non-idempotent' (duplicates are kept).

For a general discussion of positional vs. unordered representations see (Boley, 2006).

R2ML differs from RuleML, SWRL and RIF as it implements an attribute solution and defines user information content in attributes. For instance a typed object variable "?driver" is represented as follows:

```
<r2ml:ObjectVariable
r2ml:name="driver"
r2ml:classID="userv:Driver" />
```

A distinction of positional vs. slotted (named-argument) predicates and functions, as in RuleML and RIF, does not exist in R2ML.

Expressive Layering

From the perspective of knowledge representation, the main adequacy criterion for a rule markup language is its *epistemological adequacy*, which addresses the ability of the language to represent all relevant knowledge under consideration. Among other representation issues, a general rule interchange format should allow to coherently represent derivation rules, reaction rules, integrity rules, and deontic rules in a homogeneous syntax (Wagner et al, 2005). We use the following general rule classification:

- Facts may comprise various kinds of information such as asserted atoms (formulas), individual-class memberships (of ontology classes), (object-oriented) instances, stored data (e.g., relational, XML), states and event occurrences which might be qualified, e.g., by priorities, temporally, etc.
- Derivation rules infer conclusions from conditions (as in Datalog and Horn logic), where facts (see above) are a special case with constantly true conditions
- Transformation rules specify term rewriting, which can be considered as derivation rules of logics with (oriented) equality
- Integrity rules (or integrity constraints) are assertions which express conditions (or queries) that must always be satisfied. Besides enforcing data integrity, they can constrain, e.g., the rule system structure, its information content, or its behavior:

Figure 3. RuleML rule language family

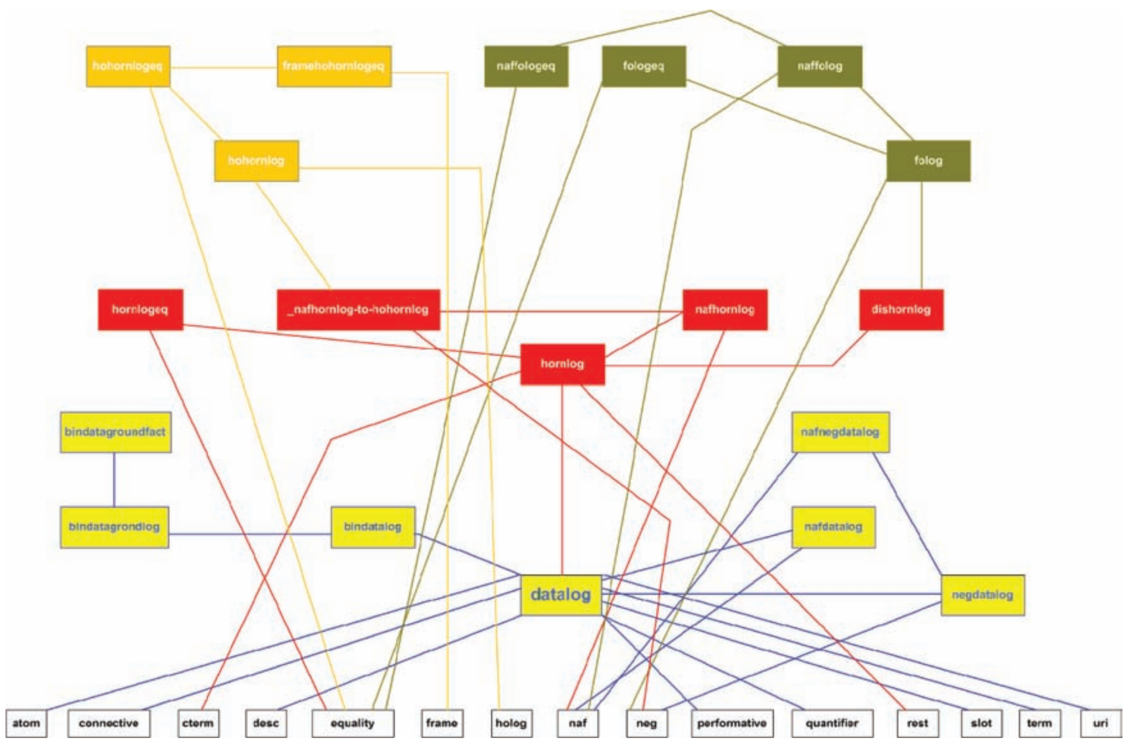
   - *Structural constraints* (deontic assignments)
   - *State constraints*
   - *Process constraints*
- Deontic rules describe rights and obligations, e.g., of institutions and agents in the context of evolving states (situations triggered by events/actions) and state transitions, where integrity rules (see above) are a special case ('introspectively') affecting the rule set itself
- Reaction rules are (behavioral / action) rules that react on occurred events (external events or changed conditions) by executing actions, where production rules are a special case with events restricted to changed conditions

Because of this broad variety of rules relevant to the Semantic Web, a general rule markup language such as RuleML should have a hierarchical structure that reflects the relevant rule dialects or sublanguages, covering the knowledge representation needs of various subcommunities (cf. Figures 3 and 4).

The main branches contain subbranches, e.g. derivation rules monotonically disallowing or non-monotonically allowing negation as failure (NAF). Branches also exhibit a layering structure with sublanguages of different expressive power, e.g. for monotonic derivation rules proceeding from function-free Horn logic (Datalog) through either full Horn logic or disjunctive Datalog up to first-order logic (FOL). This hierarchy does not form a strict tree (but a directed acyclic graph), i.e. some sublanguages are shared by several more expressive languages; e.g., a sublanguage of conditions is shared by derivation rules and reaction rules. A basic classification of rule languages is introducted by the RuleML family with Derivation Rule Markup Languages (that is, Derivation RuleML), Production Rule Markup Languages (that is, Production RuleML which is a subfamily of Reaction RuleML), Reaction RuleML Markup Languages (that is, Reaction RuleML, http://ibis.in.tum.de/research/ReactionRuleML/), and Transformation Markup Languages (that is, Functional RuleML, http://www.ruleml.org/fun/), as well as other specializations, e.g. dialects for deontic rules (e.g. covered by the RBSLA language (Paschke, 2005)), defeasible rules (Defeasible RuleML, http://defeasible.org/RuleML/) and uncertainty / fuzziness (Fuzzy RuleML, http://www.image.ntua.gr/FuzzyRuleML/).

The coverage of rule markup languages can be roughly divided into logic-based rule formalisms, usually variants of first-order predicate logic, and not logic-based rule formalisms such as (early) production rule systems. In this chapter, we mainly focus on logic-based derivation rule markup languages, but most of the general rule markup languages such as RuleML and R2ML also support the serialization of production rules and reaction rules (e.g., Reaction RuleML covers different types of reaction rule languages). In fact, RuleML and R2ML provide a roughly similar coverage, whereas, e.g., SWRL acts as a more specialized language for homogeneously combining Datalog rules with OWL, hence does not cover, e.g., reaction rules.

Figure 4. RuleML 0.91 derivation RuleML subfamily



Rules and Object Descriptions

With its URIs (http://www.w3.org/Addressing/), the Web provides a global addressing (URL) and naming (URN) mechanism for objects. A URI consists of a URI scheme name (http:, file:, etc.) followed by other information that is interpreted relative to the URI scheme. The method for assigning meanings to names varies from one URI scheme to the next, and within each scheme for different sets of names. Each scheme's specification describes how its URIs are intended to be used in certain contexts. As a result, any naming framework must provide mechanisms to enable the creation of new names while avoiding conflicts with existing ones. URIs are also central to the Semantic Web, where RDF metadata are used to describe those objects or resources with classes and properties, which are themselves defined by ontologies (in RDF Schema or OWL). Since SHOE (Heflin et al, 1999), Semantic Web rule languages have associated URIs with constant symbols, predicate names, and other language constructs for reference and disambiguation. For example, the constant symbol Georgia could be associated with the unique 'homepage' URI http://www.georgia.gov to refer to and disambiguate the state in the Southeastern U.S. in contrast to other entities having the same English name such as the country at the east coast of the Black Sea.

There have been attempts to differentiate the Web notion of URIs into two subnotions, as discussed in (Halpin, 2006): URLs (Uniform Resource Locators), for access, and URNs (Uniform Resource Names), for naming. This distinction is independent from the recent IRI (Internationalized) versions of URIs. In the context of Web knowledge representation, especially for Web rules as explored in POSL, RuleML, and RIF, three central URI uses are emerging (Boley, 2007), given here in the order of further needed research (orthogonal to research in URI normalization (Boley, 2003)).

First, a URI can be used, URL/access-style, for module import (transitive import for nested modules), where it is an error if dereferencing the URI does not yield a knowledge base valid with respect to the expected representation language.

Second, a URI can be used, URN/naming-style, as the identifier of an individual constant in the representation language, where URI dereferencing is not intended as part of the formal knowledge representation. If dereferencing is attempted as part of the metadata about the informal knowledge representation, it should retrieve a descriptive 'homepage' about the individual.

Third, a URI can be used, naming-style, as the identifier of a class, property, relation, or function, and at the same time, access-style, where dereferencing yields (a "#"-anchor into) a knowledge base formally defining that identifier (albeit perhaps partially only, as for an RDF Schema knowledge base just giving the superclasses of a class).

Here are examples for the three URI uses in connection with rules.

First, a module of U.S. states could be imported into the current rulebase using the URL/access-style URI http://modeg.org#us-state.

Second, the URI http://en.wikipedia.org/wiki/Pluto can be used URN/naming-style to refer to a celestial body originally considered a planet, as in this rule specifying its years of planethood (a URI is enclosed in a pair of angular brackets, <... >):

```
planet(<http://en.wikipedia.org/
wiki/Pluto>,AD[?year]):-
lessThanOrEqual(1930,?year),
lessThanOrEqual(?year,2006).
```

As part of the formal rule knowledge, the Pluto URI is employed only for naming. The rule can also be employed as metadata about informal knowledge through ('semantic search engine') queries like planet(?which,2005), because one of its solutions will bind ?which to the URI, whose dereferencing ('clicking') will then retrieve Pluto's Wikipedia entry.

Third, for certain formal purposes a URI like http://termeg.org#MiniVan is needed just to provide a name; for other formal purposes, also to provide a total or partial definition found by using that same URI access-style (say, the partial definition of being rdfs:subClassOf both http://termeg.org#Van and http://termeg.org#PassengerVehicle).

In most rule markup languages as well as the specific Semantic Web rule languages, the (user-defined) vocabulary names are globally unique standard identifiers in the form of URI references. Morover, they often define specific builtins for handling URIs such as the SWRL builtins *swrlb:resolveURI (from XQuery op:resolve-uri)*, which is satisfied iff the URI reference in the first argument is equal to the value of the URI reference in the second argument resolved relative to the base URI in the third argument, or *swrlb:anyURI*, which is satisfied iff the first argument is a URI reference consisting of the scheme in the second argument, host in the third argument, port in the fourth argument, path in the fifth argument, query in the sixth argument, and fragment in the seventh argument.

All classes in R2ML are URI references. A class is a type entity for R2ML objects and object variables. Similarily, a *reference property* as well as a *datatype predicate* in R2ML is a URI reference.

RIF uses *internationalized resource identifiers* or *IRIs* (symbol space rif:iri) as constants similar to RDF resources.

Rule-Ontology Combination

A rule markup language should be reasonably integrated with the Semantic Web and should be able to refer to external Semantic Web vocabularies by means of URIs or IRIs, e.g. to use their taxonomic vocabularies as type systems and their individuals as external constants/objects. Domain-independent rules can then be interpreted (relative to each vocabulary) in a domain-dependent manner (with a precise semantics). Accordingly, the original rule set can be much easier interchanged and managed/maintained in a distributed environment. Also, the core Web rule language stays compact and can be easily extended for different vocabulary languages (RDFS, OWL, OWL 2, etc.) on a "per-need-basis".

In recent years, quite an effort has been made to develop a dual expressiveness layering of assertional and terminological knowledge as well as their blends (Antoniou et al., 2005, Kifer et al, 2005). To retain decidability of querying, the *assertional bottom layer* usually consists of Datalog (function-free) assertions, perhaps restricted to unary/binary predicates. For the *terminological bottom layer*, an irreflexive version of RDF Schema's subClassOf can be employed, which could later be extended towards the rhoDF (Munoz et al., 2007) fragment of RDF. The two layers can be blended through a hybrid combination (rhoDF classes used as types for Datalog constants and variables, and subClassOf defined with order-sorted semantics) or a homogeneous integration (rhoDF classes used as unary predicates in the body of Datalog rules, and subClassOf defined as special rules with Herbrand-model semantics).

The higher layers can develop Datalog into Horn (as in Prova's or OO jDREW's hybrid implementation) and FOL (First-Order Logic) assertions, rhoDF into ALC and SHIQ terminologies with classes and properties, and appropriate blends (Rosati, 2006) (Rosati, 2006a), e.g. as advancements of our hybrid DatalogDL (Mei et al, 2007b) or homogeneous ALCuP (Mei et al, 2007). For certain purposes, especially in the early modeling phases, the assertional layers can move even beyond FOL, including towards higher-order and modal logics, as started as part of the RuleML family (Boley, 2006).

To permit the specification of terminologies independent of assertions, a hybrid approach is proposed here adopting the CARIN (Levy and Rousset, 1998) principle as a working hypothesis: A terminological predicate is not permitted in the head of a rule. Intuitively, terminological classes cannot be (re)defined by assertional clauses, because a terminology establishes more stable 'background' knowledge extended by assertions that constitute more volatile 'foreground' knowledge.

Such a hybrid lower layer can use sort restrictions as simple terminological queries in Datalog rule bodies, which in higher layers are extended to terminological queries involving properties, ALC expressions, etc. In the spirit of (Kifer et al, 2005), this should lead to a more realistic Semantic Web architecture with simplified foundations and better computational properties. Our fine-grained bottom-up approach also complements the recent differentiation of OWL-Lite into OWL 1.1 (later: OWL 2) Tractable Fragments (Grau et al., 2006).

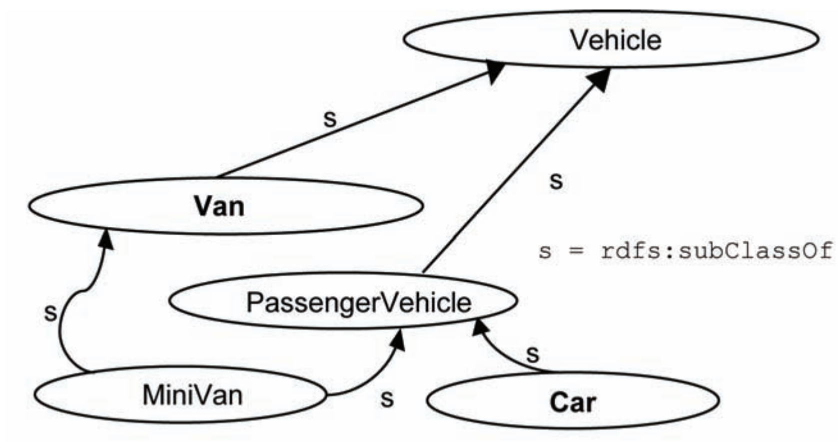
The following example uses classes of a subClassOf terminology as variable sorts (types) of slightly extended Datalog rules, namely of Horn logic rules employing (unary) functions only for measurement units.

The terminology forms a DAG (cf. Figure 5) that introduces Vehicle-rooted classes and exemplifies multiple inheritance of MiniVan from Van and PassengerVehicle (the ">" infix is used between a superclass and a subclass):

```
Vehicle > Van
Vehicle > PassengerVehicle
Van > MiniVan
PassengerVehicle > MiniVan
PassengerVehicle > Car
```

The following RuleML/POSL rules specify registration fees for vehicles. The first rule specifies a vehicle variable typed by the Van class, while the second refers to the Car class (the ":" infix is used between a variable and its type):

Figure 5. A vehicle terminology (cf. (W3C, 2000))



```
registration(?V:Van,CAD[?R:Deci
mal]):-
emission(?V,CO2[?E]),
weight(?V,kg[?W]),
emiweight(CAD[?R],CO2[?E],kg[?W
]).
registration(?V:Car,CAD[?R:Deci
mal]):-
emission(?V,CO2[?E]),
speed(?V,kmh[?S]),
emispeed(CAD[?R],CO2[?E],kmh[?S
]).
```

A registration query for a given vehicle class will thus unify only with correspondingly sorted rule conclusions, hence directly branch into the appropriate rule premises (the emiweight and emispeed premises compute the fees from the emissions as well as the weights and speeds for Vans and Cars, respectively). The previous section has shown URI-'webized' versions of these terminological classes.

R2ML rules may refer to a vocabulary which can be R2ML's own vocabulary or an imported one (such as RDF(S) and OWL). R2ML's internal default vocabulary is a serialization of a UML fragment of class diagrams. R2ML uses XML Schema datatypes as its standard datatype set. R2ML distinguishes between plain and typed literals and typed and untyped variables. A *DataTerm* is a *DataVariable*, a *DataLiteral*, or a *DataFunctionTerm*. An *ObjectVariable* is a variable that stand for objects of a particular class type, a *DataVariable* is a variable that stand for data literals, and a *GenericVariable* is a variable that does not have a type. For instance, an *ObjectVariable* contains an optional reference to a class which is used as its type:

```
<r2ml:ObjectVariable
r2ml:name="driver"
r2ml:classID="userv:Driver" />
```

R2ML allows both typed and untyped individuals. For instance, a *TypedLiteral* consist in a lexical value and a type that is an RDF datatype or a user defined datatype (subclass of rdfs:Literal):

```
<r2ml:TypedLiteral r2ml:type
Literal="xs:positiveInteger"
r2ml:lexicalValue="90"/>
```

RuleML supports order-sorted terms permitting typed individuals, variables (exemplified above) and data literals (Boley, 2003). Therefore, RuleML/XML defines an optional type attribute for specifying a term's (user-defined) type. Besides referring to the default XML Schema datatypes, typed terms may also link into external object class hierarchies via their fully qualified class names (e.g. Java classes) or taxonomies such as RDF Schema class hierarchies, thus reusing the OO class models and Semantic Web's light-weight ontologies as pluggable external order-sorted type systems. For example:

```
<Var type="rdf://
owl:Vehicle">V</Var>
<Ind type="xml://
xsd:string">abc</Ind>
<Var type="java://java.lang.
Number">X</Var>
```

A *Data* term in RuleML contains a fixed value, like an RDF literal. It may be optionally associated with an XML Schema built-in datatypeusing the xsi:type attribute. For example:

```
<Data
xsi:type="xs:dateTime">2002-10-
10T17:00:00Z</Data>
```

This open order-sorted typing approach of RuleML provides higher levels of abstractions and allows ad-hoc polymorphism with respect to coercion, i.e., automatic type conversion between subtypes, and overloading, i.e., defining multiple cases (rules with the same head except for types) taking different argument types. The ability to integrate external Semantic Web vocabularies, data types and object oriented class hierarchies as type systems provides syntactic expressiveness for easy extension of the language with domain-specific terminologies, and it facilities rule interchange across domain boundaries due to the explicit semantic definition of the used vocabulary, e.g., a Semantic Web ontology.

As in RuleML, RIF provides an optional type attribute for typed constants / individuals and a set of default XML Schema primitive data types such as xsd:long, xsd:integer, xsd:decimal, xsd:string, rdf:XMLLiteral and rif:text. For example:

```
<Const
type="rif:iri">dc:creator</
Const>
<Const type="xsd:string">abc</
Const>
```

However, variables are not typed directly in a prescriptive form using, e.g., the type attribute in the variable construct to denote that a variable *X* is of type *T*, i.e. *X:T*. Instead, RIF defines classification terms for class memberships, and also for subclass relationships (cf. F-logic's ":" and "::"):

- t#s is a *membership term* if t and s are terms.
- t##s is a *subclass term* if t and s are terms.

These classification terms are used to describe subclass hierarchies and membership constraints, e.g. expressing that a variable is of a certain class (type).

In SWRL, a homogeneous combination of OWL (OWL DL and OWL Lite) and RuleML (Unary/Binary Datalog), atoms can be of the form *C(x)*, *P(x,y)*, *sameAs(x,y) differentFrom(x,y)*, or *builtIn(r,x,...)* where *C* is an OWL description or data range, *P* is an OWL property, *r* is a built-in relation, *x* and *y* are either variables, OWL individuals or OWL data values, as appropriate. In the context of OWL Lite, descriptions in atoms of the form *C(x)* may be restricted to class names. That is, SWRL defines a rule language on top of OWL ontologies and hence directly supports the definition of class ontologies and their properties which can be used to type variables. For an example, see Figure 6.

Figure 6.

```
<!-- Each person that is a qualified driver can be added to a car rental as
additional driver-->
<ruleml:Implies
  xmlns:ruleml="http://www.ruleml.org/0.91/xsd"
  xmlns:owlx="http://www.w3.org/2003/05/owl-xml"
  xmlns:swrlx="http://www.w3.org/2003/11/swrlx"
  xmlns:srv="http://www.eurobizrules.org/ebrc2005/eurentcs">

  <ruleml:body>
    <swrlx:classAtom>
      <owlx:Class owlx:name="srv:Rental"/>
      <ruleml:Var>rental</ruleml:Var>
    </swrlx:classAtom>
    <swrlx:classAtom>
      <owlx:Class owlx:name="srv:Person"/>
      <ruleml:Var>person</ruleml:Var>
    </swrlx:classAtom>
    <swrlx:classAtom>
      <owlx:Class owlx:name="srv:QualifiedDriver"/>
      <ruleml:Var>person</ruleml:Var>
    </swrlx:classAtom>
  </ruleml:body>
  <ruleml:head>
    <swrlx:individualPropertyAtom swrlx:property="srv:additionalDriver">
      <ruleml:Var>rental</ruleml:Var>
      <ruleml:Var>person</ruleml:Var>
    </swrlx:individualPropertyAtom>
  </ruleml:head>
</ruleml:Implies>
```

This homogeneous integration approach is adopted by R2ML from SWRL, while in RuleML without OWL one would refer to the external ontology which defines the vocabulary classes and their properties.

EXTERNAL DATA INTEGRATION AND DATA PROCESSING

Often Web rules refer to or describe functions and queries over data stored in an external database which can be anything from log files to Web sources or relational databases, data warehouses, or XML or RDF databases such as native XML databases or RDF triple stores. The rule language must allow for the direct dynamic integration of these secondary data storages as facts or object values into the rules in order to reduce redundancy and high memory consumption. It should also support outsourcing of expensive (pre-)processing of data to external systems, e.g., of mathematical functions to procedural implementations such as Java, or of SQL/SPARQL aggregation queries (constructive views) to database management systems or RDF triple stores. A tight combination of declarative and object-oriented programming with rich procedural attachments and language built-ins, e.g. for querying, will facilitate the integration of existing functionalities, tools, and external data sources into rule executions at run time.

Procedural attachments are procedure calls to external user-defined computational models of a standard programming language, e.g., directly to

Figure 7.

```
<swrlx:builtinAtom swrlx:builtin="&swrlb;#multiply">
    <ruleml:var>inches</ruleml:var>
    <ruleml:var>feet</ruleml:var>
    <owlx:DataValue owlx:datatype="&xsd;#int">12</owlx:DataValue>
</swrlx:builtinAtom>
```

Java or C# methods. Therefore, procedural attachments are a crucial extension of a modern Web rule language. They permit the combination of the benefits of declarative (rule-based) as well as procedural and object-oriented languages, e.g., to delegate computation-intensive tasks to optimized object code or to invoke procedure calls on object methods which cannot be easily expressed in a declarative rule-based way. Procedural attachments should be supplemented with a typed logic approach with external type systems such as Java or Semantic Web ontologies, e.g. to assign external objects to typed variables, and with mode declarations in order to safeguard the usage of built-ins and calls to external functionalities.

(Procedural Attachments). A procedural attachment is a function or predicate whose implementation is given by an external procedure. Two types of procedural attachments are distinguished:

- *Boolean-valued attachments (or predicate attachments)* which call methods that return a Boolean value, i.e., that are of Boolean sort (type).
- *Object-valued attachments (or functional attachments)* which are treated as functions that take arguments and return one or more objects, i.e., that are of a function sort. This also includes access to public object fields.

(Built-Ins). Built-in predicates or functions are special restricted predicate or function symbols in the rule language for concrete domains, e.g., built-ins for strings, numerics, Boolean values, date, time, intervals, lists, etc.

All Web rule languages discussed in this chapter provide support for built-ins and some of them also for general procedural attachments.

SWRL provides an extensible library of built-in functions (http://www.daml.org/2004/04/swrl/builtins.html) co-developed with RuleML. SWRL's built-ins approach is based on the reuse of existing built-ins in XQuery and XPath, which are themselves based on XML Schema Part 2: Datatypes. SWRL built-ins are called via a built-in atom, swrlx:builtinAtom, which identifies a built-in using the swrlx:builtin attribute and lists its arguments as subelements. SWRL built-ins are identified using the http://www.w3.org/2003/11/swrlb namespace, currently also used by RuleML. This is an example of calling the multiply built-in (see Figure 7).

SWRL does not provide direct support for procedural attachments, but it could easily adopt this feature from Reaction RuleML.

R2ML by default supports SWRL and XPath2 built-ins as predicate names of atoms *r2ml:DatatypePredicateAtom* and symbols of functions *r2ml:DatatypeFunctionTerm*. Functions and operators like addition, subtraction, etc. are translated into corresponding R2ML function terms. The operands of the functions implied by the built-ins are enclosed by *r2ml:dataArguments* and might be class attributes, class operations, data variables, typed variables, or further nested built-in functions. However, mode declarations are missing (see Figure 8).

R2ML supports procedural attachments in order to access public data fields of objects which might be bound to object variables (see

Figure 8.

```
<r2ml:DatatypePredicateAtom
 r2ml:datatypePredicate="swrlb:lessThan">
   <r2ml:dataArguments>
      <r2ml:DataVariable r2ml:name="y"/>
      <r2ml:TypedLiteral r2ml:lexicalValue="4"
                         r2ml:datatype="xs:positiveInteger"/>
   </r2ml:dataArguments>
</r2ml:DatatypePredicateAtom>
```

Figure 9.

```
<r2ml:AttributeFunctionTerm r2ml:attributeID="userv:Car.price">
   <r2ml:contextArgument>
      <r2ml:ObjectVariable r2ml:name="car"
                           r2ml:classID="userv:Car"/>
   </r2ml:contextArgument>
</r2ml:AttributeFunctionTerm>
```

Figure 9).

For reactive rules such as production rules, R2ML supports assignments of action expressions in order to call object methods as actions in the action part (see Figure 10).

The RIF built-ins (http://www.w3.org/2005/rules/wiki/DTB) overlap with the functions and predicates defined in XQuery 1.0 and XPath 2.0 Functions and Operators.

Syntactically, built-in predicates and functions in RIF are enclosed by external terms of the form:

```
'External' '(' Expr ')'
```

where Expr is a UNITERM, i.e. either a Boolean-valued function expression / predicate or an object-valued functional expression. Since RIF does not support a general typed rule language, it requires special guard predicates for all of its supported datatypes to ensure the correct usage of the arguments of built-ins:

Figure 10.

```
<r2ml:AssignActionExpression r2ml:propertyID="status">
   <r2ml:contextArgument>
      <r2ml:ObjectVariable r2ml:name="ticket"/>
   </r2ml:contextArgument>
   <r2ml:TypedLiteral r2ml:lexicalValue="Escalate"
                      r2ml:datatypeID="xs:string"/>
</r2ml:AssignActionExpression>
```

Figure 11.

```
<!— a call to a builtin function -->
<Expr>
   <Fun per="builtin" uri="swrlb:stringConcat"/>
   <Var type="java://java.lang.String" mode="+">String1</Var>
   <Var type="java://java.lang.String" mode="+">String2</Var>
</Expr>

<!-- a call to a builtin predicate -->
<Atom>
   <Rel per="builtin" uri="rif:dateTime-equal"/>
   <Var type="xml://xs:dateTime" mode="+">Time1</Var>
   <Var type="xml://xs:dateTime" mode="+">Time2</Var>
</Atom>
```

```
External("op:numeric-greater-
than"^^rif:iri(
?diffdays
"10"^^xsd:integer))
External(
"www.w3.org/2007/rif-builtin-
predicates#isInteger"^^rif:iri(
?diffdays))
```

Note that the above example shows the RIF presentation syntax, not the concrete RIF XML syntax.

RIF-FLD foresees procedurally attached user-defined function terms or predicates to be wrapped as external terms but does not define a concrete approach for calling procedural actions yet. However, it supports frame terms *t[p1->v1 ... pn->vn]* which can be used to describe properties of objects.

The RuleML family (through its Reaction RuleML branch) provides an open flexible approach for pluggable external built-in libraries safeguarded by type and mode declarations. It explicitly denotes the usage by the attribute per= "*plain|value|effect|modal|builtin*" on functional expressions and atomic relations. A <*Rel*> or <*Fun*> using "plain" is left uninterpreted, using "*value*" is interpreted purely for its value, using "*effect*" is interpreted impurely both for its value and its (side-)effect action, e.g. by a procedural attachment, using "*modal*" is interpreted as pure modality, and using "*builtin*" as a built-in (Figure 11).

The mode ("+": input; "-": output; "?": input or output) and type declarations ensure the correct usage of arguments in built-ins, i.e. that built-ins are called with ground values (not free variables) of the expected types.

RuleML provides a concise integration of procedural attachments. Methods of external object classes can be called, including calls to object constructors and calls to object instance and static object methods as well as access to public object fields. Constructed objects and returned result objects can be assigned to variables. Nested selection patterns can be defined over the result object collections such as "forall ?X where ?X=Person(age > 30 and age < 40)" (see Figure 12).

Most of the specific Semantic Web rule languages such as Jena and Prova support all "standard" built-ins of Web Rule languages as well as many additional built-ins e.g. for meta interpretations of literals, exception handling, console printouts, collections, iterations/enumerations, object property constraints, or access to system environment properties. For instance, Prova supports several query built-ins to access

Figure 12.

```
<!-- Assign the constructed Java object to the variable
     Date = java.io.Calendar.getInstance() -->
<Equal>
  <Var>Date</Var>
  <Expr>
     <!-- class -->
     <oid><Ind uri="java://java.util.Calendar"/></oid>
     <!-- constructor -->
     <Fun per="effect">getInstance</Fun>
  </Expr>
</Equal>

<!-- Use the bound object of the variable and call a function
     "isSet" of the object -->
<Atom>
   <!-- object previously assigned to Date -->
   <oid><Var>Date</Var></oid>
   <Rel per="effect">isSet</Rel>
   <Data>1</Data>
</Atom>

<!-- Call a static C# method -->
<Atom>
  <oid><Ind uri="c-sharp://System.Console"/></oid>
  <Rel uri="WriteLine"/>
  <Data>Hello World</Data>
</Atom>
```

files, XML data sources via DOM, XPath, and XQuery, RDF data sources via RDF triples and SPARQL and RDFS/OWL ontologies, as well as various homogeneous or heterogeneous inference queries using external DL reasoners such as, e.g., Pellet. Prova also provides a tight and natural Java integration. Methods of classes in arbitrary Java packages can be dynamically invoked from Prova rules. The method invocations include calls to Java constructors creating Java variables and calls to instance and static methods for Java classes as well as public object data fields.

FUTURE TRENDS

A general rule markup language such as RuleML or RIF covers many different rule types and rule families. Some of the language families such as classical production rules historically only define an operational semantics, while other rule families such as logical rules (see RuleML family in the section about expressive layering) are based on a model-theoretic and/or proof-theoretic semantics. A general research question is whether there exists a unifying semantic framework for all different rule types. Work in this direction is pursued, e.g. in RIF (http://www.w3.org/2005/rules/wiki/FLD) and Reaction RuleML (transactional transition semantics for reaction rules subsuming all other RuleML rules). However, since there is no general consensus on one particular semantics for all expressive rule languages, an exclusive commitment to one particular semantics for a Web rule language should be avoided (even in well-researched fields such as logic programming several semantics such as well-founded semantics and answer set semantics are competing). Nevertheless, for certain subfamilies a preferred semantics can still be given and semantic mappings between rule families be defined.

General rule markup languages need to include practical language constructs which might not (yet) have a standard formal semantics based on classical model-theoretic logic. For instance, procedural calls to external (object) functions, operational systems, data sources and terminological descriptions, are often vital to deal with practical real-world settings of distributed Web applications. Recent research, e.g. in RuleML and RIF-PRD, is done on adopting such practical language constructs without a standard formal semantics but with a non-standard one. While there is a risk that these concessions to non-standard semantics might endanger the benefits of formal semantics for the overall rule language, they turn out to be a crucial means to avoid limitations of standard rule representations in the exploration of rule markup languages. The rule component will rarely run in isolation, but interact with various external components, hence call for functionalities such as efficient object-oriented or relational/SQL-style retrieval and aggregation methods that are common in modern information systems.
